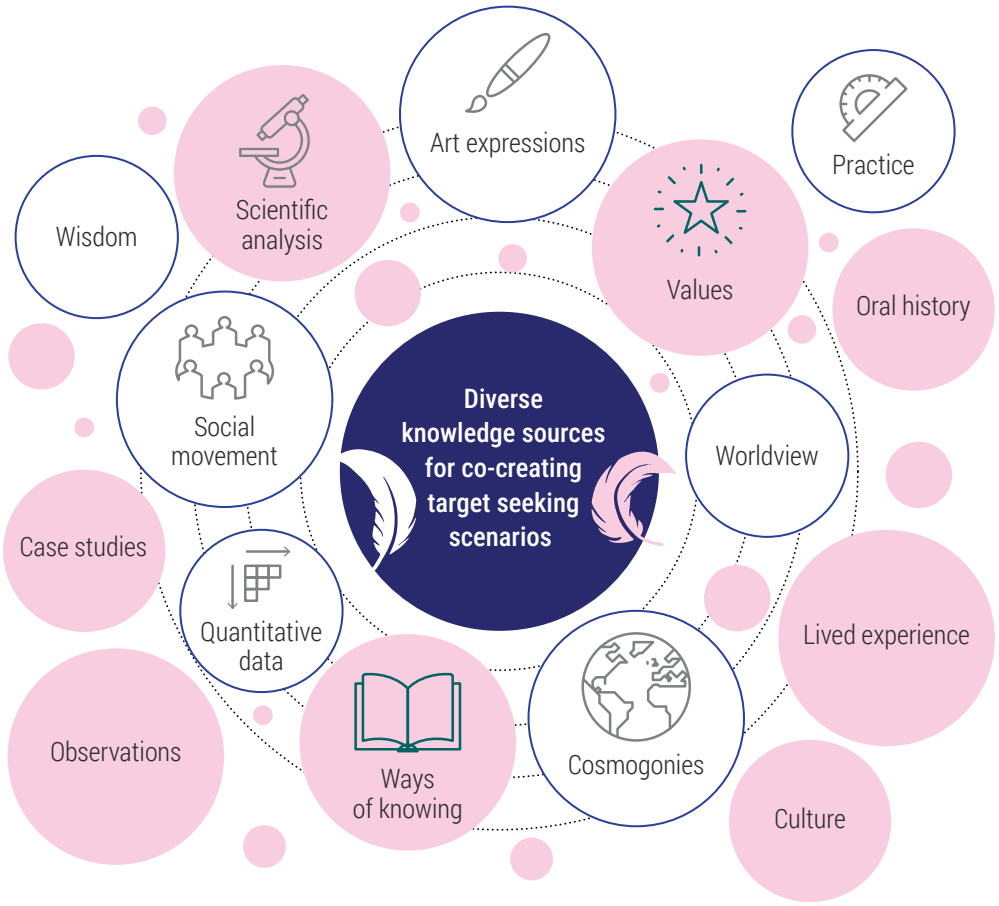
Transformation Pathways towards Achieving Global Goals: Global Implications



Indigenous Knowledge and Local Knowledge Chapeau C

Perspectives from Indigenous Knowledge and Local Knowledge can foster a co-creation process that is necessary for building responsible and resilient scenarios for future generations. Indigenous Knowledge and Local Knowledge play an active role in the generation of relational understanding, which often includes gender-specific experiences (Jessen 2021; Ibarra et al. 2023; IK & LK Dialogues 2025).

In addition to enabling holistic insight into ongoing environmental challenges and possible futures, need to center Indigenous Knowledge and Local Knowledge perspectives in scenario analysis. Existing scenario approaches struggle to engage the knowledge, observations, and aspirations of Indigenous Peoples (Aguiar et al. 2020; Pereira et al. 2021). Indeed, scenario analysis typically relies on quantifiable indicators, while Indigenous Knowledge and wisdom cannot be easily quantified. If not handled carefully, scenario analysis can lead to disempowerment of place-based narratives, erosion of trust-building and result in the silencing or appropriation of Indigenous Knowledge (Bates 2007; Camara-Leret et al. 2019; Carmona et al. 2023). Indigenous perspectives involve cyclic rather than linear relationships, along with unique forms of sentience between humans and non-human beings, which can be difficult or even incommensurable to capture in conventional scenario frameworks (Natcher et al. 2007; Cadman et al. 2023).

The co-creation of knowledge is an approach to intercultural collaboration that shares different types of knowledge and experiences to inform high-level policy decisions (Brock et al. 2024; IK & LK Dialogues 2025). This approach values multiple knowledge systems promoting equity between knowledge holders while expanding the scope of data in modelling exercises. By centring Indigenous Knowledge and Local Knowledge in the co-creation process, new scenario analysis can better represent changes occurring across different locations and ecological systems, capturing nuances that might be overlooked by conventional scientific approaches alone (Pearman-Gillman et al. 2020; Cadman et al. 2023). This inclusive approach supports the development of diverse and culturally relevant future scenarios, which are crucial for achieving global policy commitments, such as climate change mitigation, land and biodiversity conservation, and access to resources (Ibarra et al. 2023). These new scenarios, which employ Indigenous approaches to scenario building, can inform local actions, ensuring that global goals are translated into context-relevant strategies (Hérivaux et al. 2021; Hallberg-Sramek et al. 2023). Poor in-depth knowledge and limited willingness to engage with Indigenous Peoples knowledge systems have led to the neglect of Indigenous needs, values and observations in scenario planning (Jesse et al. 2021). During the GEO-7 Indigenous Knowledge and Local Knowledge Dialogues, participants provided

Figure C.1: Diverse knowledge sources for co-creating target seeking scenarios that sustain people and Mother Nature

Note: Worldviews refer to how humans and other entities exist and co-exist in places (e.g., communities, countries, or the planet), which can inform how different knowledge systems understand what is real. Cosmogonies are predominant among Indigenous Peoples, referring to how humans are related to their surroundings, where values like relationality and reciprocity are key to observing, respecting, and sustaining Mother Nature. In this context, multiple methodologies can be used, such as arts, quantitative data, observation, listening, scientific analysis, etc. To truly enable a co-creation space, it is necessary to intentionally balance power asymmetries and apply rights-based frameworks to ensure that Indigenous Peoples and their knowledges are equitably included in the co-creation process and are not exploited.

Source: adapted from Global Alliance for the Future of Food (2021)

key insights on desirable futures and pathways to achieve environmental and social sustainability (IK & LK Dialogues 2025).

Additionally, they stressed the urgency of addressing historical and current injustices especially those tied to colonial legacies and violations of Indigenous rights as essential for fostering reconciliation and decolonization for the next generations from the Haudenosaunee (Iroquois) Indigenous Peoples to respect and honour both ancestors and descendants. It is a way to stay connected with ones past family and show care for those yet to be born, reflecting a perspective of continuity. For scenario planning to be effective, it must recognize Indigenous Peoples inherent rights, including their customary land rights, self-determination, Indigenous data sovereignty and Free,Prior and Informed Consent (FPIC). At the same time, it must address the legacy of colonialism in science and the education system, particularly concerning cultural suppression, forced relocation and social exclusion (IK & LK Dialogues 2025). Furthermore, the involvement of Indigenous Peoples in designing, reviewing and implementing the outcomes of the co-creation process is essential to minimize the risk of unintentional harm. Their participation also ensures that the resulting practices are culturally appropriate and aligned with gender-specific roles and responsibilities, thereby reducing the risk of excluding women, girls, and elders (Mayo D'Arrigo 2019; Hallberg-Sramek et al. 2023; Jacobi et al. 2022).

Chapter summary

Credit: Ikunl/Envato

Scenario analysis helps envision plausible futures, which can be assessed both qualitatively using narrative and quantitatively using models (*well established*). Scenarios provide a simplified description of how the future may unfold, based on a coherent and internally consistent set of assumptions about key driving forces and their interrelationships. The qualitative narratives and quantitative models used in scenario development complement each other. Narratives provide an overall logic, while models allow the elaboration of possible trends for those parameters that can be quantified. By considering the interrelations between different systems, environmental and socioeconomic challenges, and social groups, model-based scenarios can help address synergies and trade-offs among various developments, aspirations and measures. {9.2}

The scenario analysis in GEO-7 examines the environmental and socioeconomic implications of continuing today's trends, as well as alternative routes that address the global environmental crises. The *Current Trends Scenario* is an explorative scenario and represents a continuation of current policies and practices. It is used to assess the environmental and socioeconomic implications of failing to address the global environmental crises effectively. The target-seeking scenarios are normative scenarios that describe alternative routes to achieve a set of internationally agreed goals related to the global environmental crises. The goals include limiting global warming in line with the Paris Agreement, halting and reversing biodiversity loss in line with the Kunming-Montreal Global Biodiversity Framework, and achieving land degradation neutrality in line with the United Nations Convention to Combat Desertification 2018–2030 Strategic Framework, alongside improving air quality, ending hunger, and achieving universal access to clean water and modern energy services in line with related Sustainable Development Goals. {9.2, 9.3}

Two contrasting target-seeking scenarios are developed, representing Transformation Pathways, that combine different solutions across the five systems to achieve internationally agreed goals. Multiple pathways are possible and can

coexist in different contexts. To facilitate the understanding of the core assumptions and how they affect different systems, for this 7th Global Environment Outlook (GEO-7) report, two contrasting scenarios are developed and discussed. Their narratives are based on alternative assumptions about societal values and approaches to solving global environmental crises while improving human well-being. Both affect production and consumption patterns, as well as environmental management, but with a diverging rationale, assuming different forms of structural change in society. The *Behaviour-focused Transformation Pathway* envisions a profound transformation in society's values, beliefs and norms, accompanied by a significant decrease in consumption, particularly in affluent countries. The *Technology-focused Transformation Pathway* envisions massive investments in technology development, aiming for efficiency and clean-technology gains in an economically globalized, commodified, liberal and urbanized world. Based on these general assumptions, the two scenarios combine specific solutions for each system. {9.4}

The Transformation Pathways can foster discussions about possible pathways towards a more sustainable future among multiple actors at different levels (*well established*). The pathways are neither predictions nor prescriptions, and no likelihood is attached to them. Instead, they illustrate, under a set of general and system-specific internally consistent assumptions, how different interrelated systems may dynamically evolve over time and what their environmental and socioeconomic implications are. They are archetypes of alternative transformations and act as a heuristic device to explore the solution space of possible pathways to achieve internationally agreed goals. As such, they illustrate – in general terms – the type, extent and effort required to meet the goals; the critical choices involved; related socioeconomic implications; the associated synergies and trade-offs across the goals, measures, and systems; and the possible challenges and opportunities that may arise. They are aimed at fostering discussions about possible pathways towards a more sustainable future, among multiple actors at different levels. {9.2, 9.4}

The GEO-7 scenario methodology combines unique narratives with a suite of well-established and linked models to describe diverse aspects of the future evolution of human and environmental systems in an interactive way. New narratives were constructed to illustrate alternative transformations of the five systems, and a suite of models is used to quantify these narratives. Together, these models cover key elements of the five systems, global environmental crises and their related goals, and the environmental and socioeconomic implications. The models are linked to enable cross-system interactions and thereby enhance the representation of the overall system by explicitly accounting for critical interdependencies and feedback between the component models. Results are compared with established scenario databases and existing literature to address uncertainty and consistency with the broader scenario community. While the methodology provides valuable insights, it is limited in terms of scenario scope, issue coverage and the level of aggregation. {9.4, 9.5, 9.6}

9.1 Introduction

Part B of this assessment demonstrates that most environmental systems are under severe pressure and that trends in environmental degradation are on the rise. These trends are disrupting people's lives and their livelihoods worldwide. Key questions for Part C include:

- What are the likely environmental and socioeconomic implications of a continuation of these trends? and
- What is needed to achieve internationally agreed goals related to the global environmental crises – climate change, biodiversity loss and land degradation, and pollution and waste – and to ensure this also helps achieve the Sustainable Development Goals (SDGs)?

To address these questions, three scenarios are developed, utilizing both qualitative and quantitative methods. This chapter presents the methodological approach for developing these scenarios.

9.2 Explorative and target-seeking scenarios

Scenarios provide simplified descriptions of how the future may take shape based on a coherent and internally consistent set of assumptions about key driving forces and their relationships (Raskin et al. 2005; van Vuuren et al. 2012; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem [IPBES] 2016). They can contain a combination of qualitative and quantitative elements using narratives and models (Raskin et al. 2005). These elements complement each other, as narratives can provide an overall logic while models can help elaborate possible trends for those parameters that can be quantified (**Figure 9.1**). Furthermore, where narratives can include important qualitative factors such as values, behaviour and institutions, model-based scenarios offer structure, discipline and rigour (Raskin et al. 2005). By considering the interrelations of different systems, environmental and socioeconomic challenges, and social groups, model-based scenarios can help address synergies and trade-offs among various developments, aspirations and measures.

Many scenarios have been discussed in the scientific literature (Lauer et al. 2024) and used in global environmental assessments (UNEP 2021) such as the Intergovernmental Panel on Climate Change (IPCC 2018; IPCC 2022), Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem (IPBES 2019), United Nations Convention to Combat Desertification (UNCCD 2022) and United Nations Environment Programme (UNEP 2024). In earlier Global Environmental Outlooks (GEOs), scenario analysis has played a prominent role (Bakkes et al. 2022), with the emphasis shifting from what could happen using exploratory scenarios (UNEP 2002;

Credit: image Envato

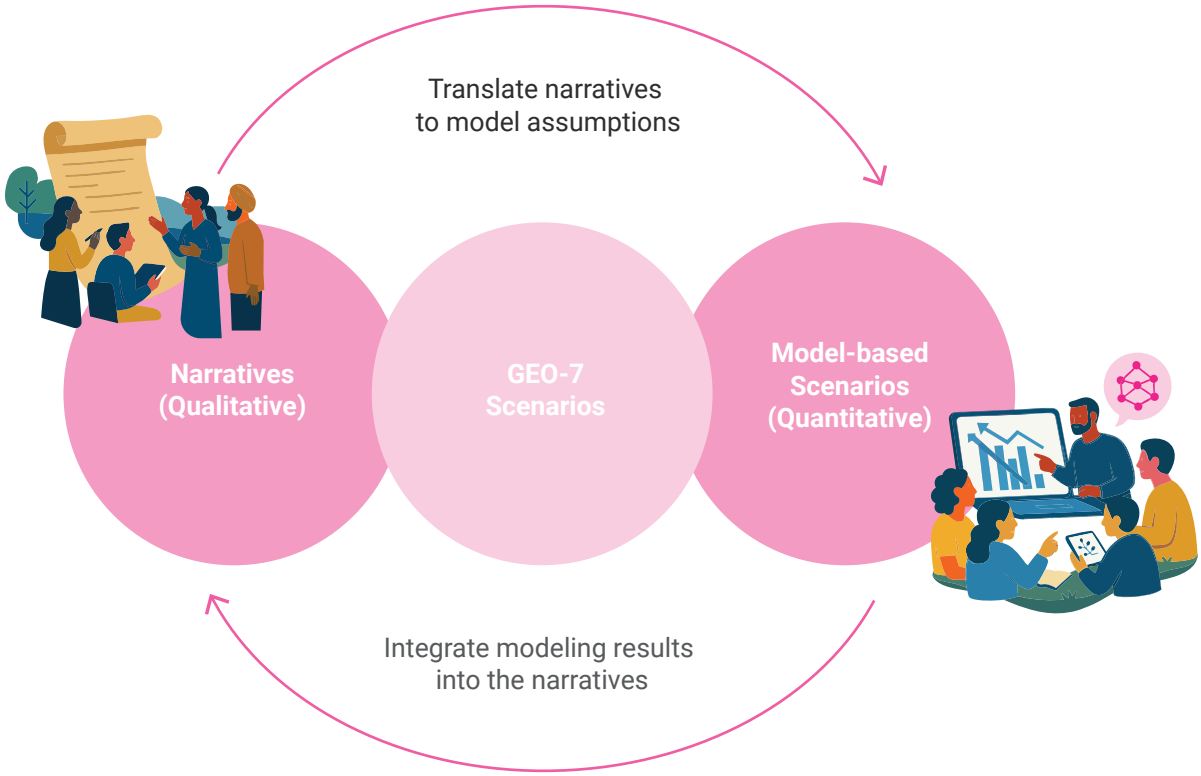
UNEP 2007) to what should happen using normative target-seeking scenarios (UNEP 2012; UNEP 2019).

Building on previous assessments, particularly GEO-6, the emphasis in GEO-7 is on systems transformation to achieve internationally agreed goals related to the global environmental crises. As the scenario literature addressing this question is limited, GEO-7's Outlook Chapters (Part C: Chapters 9, 10 and 11) provide a comprehensive and tailored analysis of new scenarios. Other new elements include a focus on the five systems of economy and finance, food, energy, materials and waste, and environment; an assessment of both environmental and socioeconomic implications of system transformation; and an accounting of plural, conditional possible futures through the development of two distinct Transformation Pathways.

To address the overarching questions of GEO-7, three scenarios are developed: one exploratory scenario called the Current Trends scenario and two alternative target-seeking scenarios, outlined as Transformation Pathways (**Figure 9.2**). The methodology is based on the Story and Simulation approach (Alcamo 2008; Elsawah et al., 2020), which combines qualitative and

Credit: image Envato

Figure 9.1: Feedback and complementary aspects between qualitative and quantitative aspects of the GEO-7 scenarios



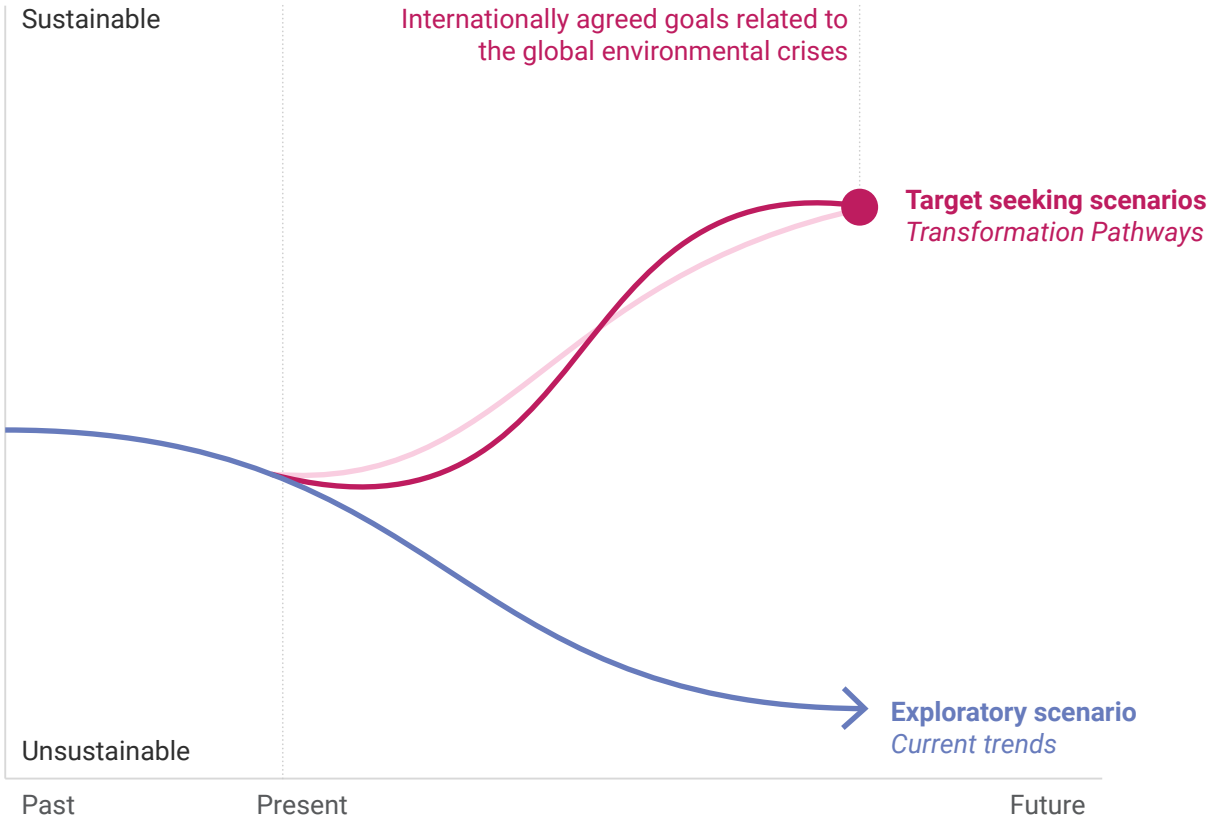


Figure 9.2: Scenarios used in the outlook chapters

quantitative elements. For the Current Trends scenario, the narrative is based on O'Neill et al. (2017), while the narratives for the two Transformation Pathways are specifically developed for GEO-7 (Section 9.4). All three scenarios are formalized using analytical models (Section 9.5). The narratives provide consistency in assumptions across the five systems to enable quantification, while they are also critical to facilitate the understanding and analysis of the quantitative results.

The Current Trends Scenario describes how the five systems develop under a continuation of current trends and efforts, and allows for an assessment of environmental and socioeconomic implications in the absence of stricter policies to address the global environmental crises. It is based on the middle-of-the-road scenario of the Shared Socioeconomic Pathways (SSPs), which describes a world that "…follows a path in which social, economic, and technological trends do not shift markedly from historical patterns…" (O'Neill et al. 2017). While the SSPs were developed principally to support climate change research (van Vuuren et al. 2014), they have also been used for other fields, including biodiversity loss (Pereira et al. 2024), land degradation (van der Esch et al. 2021) and air pollution (Rao et al. 2017). The scenario is not a simple extrapolation of recent experience but rather a development pathway that is consistent with typical patterns observed in the past. The scenario does not include policies and policy objectives that are currently being implemented. While such climate change-related policies are relatively well recognized and utilized in scenario studies (UNEP 2024), this is not the case for the other global environmental crises. Moreover, the primary objective is to examine the likely outcomes of current trends.

The two Transformation Pathways are normative. They describe alternative routes to a desired future scenario defined by a set of internationally agreed goals (Section 9.3). They allow assessment of the required extent and effort, the related socioeconomic implications, key interactions across the five systems, the critical choices involved, and the associated synergies and trade-offs across goals, as well as potential challenges and opportunities. They are driven by integrated solutions that transform the five systems based on alternative assumptions about

societal values and approaches to solving the global environmental crises while improving human well-being. It is crucial to recognize that these Transformation Pathways outline what can be achieved in each system to attain the desirable futures but do not specify how to implement these solutions. The implementation of Solution Pathways is discussed in Part D, Chapters 12–18.

The three scenarios are not predictions or prescriptions, nor is there any likelihood attached to them. Instead, they illustrate, under a set of general and system-specific internally consistent assumptions, how different interrelated systems may dynamically evolve over time and what their environmental and socioeconomic implications are. The two Transformation Pathways are archetypes of alternative possible transformations. They are not mutually exclusive but act as a heuristic device to explore the solution space of possible pathways to achieve globally agreed goals. As such, they aim to foster discussion about possible pathways towards more sustainable futures among multiple actors at different levels.

9.3 Internationally agreed goals used in the scenario analysis

The scenario analysis is guided by a selection of internationally agreed goals related to the global environmental crises (**Table 9.1**). The GEO-7 Current Trends Scenario is used to assess the extent to which these goals are being achieved without stepped-up efforts. In contrast, the two Transformation Pathways are used to illustrate different combinations of measures tailored to achieve these goals.

Given the modelling complexity, the set of goals includes one goal per global environmental crisis. The broader complexity and impacts of the global environmental crises, for example the multiple dimensions of biodiversity, aquatic systems, and the broad range of pollutants, are discussed in Part B, Chapters 3–6, although not in a forward-looking perspective. For each goal, an indicator and a target value are defined in line with international treaties and agreements. The goals for climate change, and biodiversity loss and land degradation are based on the agreed goals within their respective Rio Conventions: The United Nations Framework Convention on Climate Change (UNFCCC), the Convention on Biological Diversity (CBD) and and the United Nations Convention to Combat Desertification (UNCCD). Where possible, the goals link to specific SDG targets. For pollution and waste, the goal is based on the 2030 Agenda for Sustainable Development.

- The climate change goal is based on the long-term temperature goal of the Paris Agreement: "…holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels…" (UNFCCC 2015). Global mean temperature increase is used as an indicator to assess future trends in climate change.

- The goal for biodiversity loss is based on the Kunming-Montreal Global Biodiversity Framework (GBF) of the United Nations Convention on Biological Diversity (CBD 2022). Goal A of the GBF is about protecting and restoring biodiversity to bend the trend of biodiversity loss, with increasing biodiversity again by 2050. Target 1 aims to reduce the loss of areas of high biodiversity importance to near zero by 2030. To assess trends in biodiversity loss, the Mean Species Abundance indicator is used, which measures biodiversity intactness (Schipper et al. 2020; Pereira et al. 2013). Given the modelling constraints, the analysis focuses on terrestrial systems only.

- The goal for addressing land degradation is based on the UNCCD 2018–2030 Strategic Framework (UNCCD 2018) and the GBF (CBD 2022). The overall goal of the UNCCD is to achieve land degradation neutrality. Target 2 of the GBF is to restore 30 per cent of degraded ecosystems by 2030. To assess trends in land degradation, two of the three SDG 15.3 sub indicators are used – land cover and soil organic carbon – as these are sufficiently well represented in the model framework.

- The pollution goal focuses on air pollution and is based on SDGs 3.9 and 11.6 (United Nations 2015) and the World Health Organization (WHO) air quality guidelines (WHO 2021). Ambient air pollution and toxic chemical pollution are among the most pressing and increasing modern risks to human and planetary health, with air pollution causing the highest number of deaths from environmental factors and

Table 9.1: Goals to be achieved in the two Transformation Pathways.

	Goal	Indicator	Target value	Global agreement	Related SDG target
Climate change	Limit global warming	Global mean temperature increase	1.5° C by 2100	Paris Agreement (UNFCCC 2015)	SDG 13
Biodiversity loss	Protect biodiversity	Mean Species Abundance in terrestrial systems	No further loss of biodiversity by 2030 and an increase towards 2050	Kunming-Montreal Global Biodiversity Framework (CBD 2022)	SDG 15.5
Land degradation	Achieve land degradation neutrality	Conversion of natural land and soil organic carbon	Halt loss of natural land by 2030; increase in soil organic carbon on 30% and 50% of agricultural lands by 2030 and 2050	UNCCD 2018-2030 Strategic Framework (UNCCD 2018); Kunming-Montreal Global Biodiversity Framework (CBD 2022)	SDG 15.3
Pollution	Improve air quality	Population exposed to ambient $PM_{2.5}$ > 25 µg/m³	<20% by 2030 and <10% by 2050	2030 Agenda for Sustainable Development (UN 2015) and WHO air quality guidelines (WHO 2021)	SDG 3.9 and 11.6
Food security	End hunger	Prevalence of undernourishment	0% by 2050*	2030 Agenda for Sustainable Development (UN 2015)	SDG 2.1
Water access	Achieve universal access to safe drinking water and adequate sanitation	Population using safely managed drinking water services and population using safely managed sanitation services	100% by 2050*	2030 Agenda for Sustainable Development (UN 2015)	SDG 6.1 and 6.2
Energy access	Ensure universal access to modern energy services	Population with access to electricity and population with primary reliance on clean fuels and technology	100% by 2050*	2030 Agenda for Sustainable Development (UN 2015)	SDG 7.1

Note: * Given that these SDGs are still largely off-track and the short time frame between publication of GEO-7 and 2030, the target year of the SDGs, the target year for these goals has been extended to 2050.

being the second-largest of all factors globally (Fuller et al. 2022). The WHO air quality guidelines include health-based, quantitative recommendations aimed at substantially reducing the health risks associated with exposure to ambient air pollution (WHO 2021). To assess trends in air pollution, the second interim target for $PM_{2.5}$ of 25 µg/m³ was selected, which coincides with the annual average threshold value of the European Union. The target values are based on van Vuuren et al. (2022).

There can be trade-offs between addressing the environmental crises and achieving human development goals if the transformations are not well-managed. To account for these interlinkages in the Transformation Pathways, three additional human development goals are incorporated into the set. These goals address the basic material needs aspect of human well-being (Rao and Min 2018) and are based on the 2030 Agenda for Sustainable Development (United Nations 2015). They include ending hunger (SDG 2.1), achieving universal access to safe drinking water and adequate sanitation (SDG 6.1 and SDG 6.2), and ensuring universal access

to modern energy services (SDG 7.1). Achieving these goals imposes additional constraints on the food, energy and resource systems. Including these additional targets in the analysis of Transformation Pathways provides good insights into the required effort for achieving environmental and human well-being goals simultaneously. Achieving many other SDGs have implications for resource use too and the three chosen SDGs have a much broader scope than only providing basic material needs. However, given the complexity involved, including the broad scope of the SDGs, it is impossible to address with the global models involved.

The two Transformation Pathways are designed to meet the seven goals simultaneously. In addition to these seven goals, a much broader set of indicators is used to assess the environmental and socioeconomic implications associated with the three scenarios. These indicators are based on the 2030 Agenda for Sustainable Development (UN 2015). For the assessment of environmental implications, additional indicators for water nutrient pollution (SDG 6.3) and freshwater scarcity (SDG 6.4) are used. To assess the socioeconomic implications, a range of indicators is used, structured according to Amartya Sen's development-as-freedom approach (Sen 1999). This approach defines the impact on human well-being as the effects on the freedom of choices and actions to meet basic material needs, achieve good health, attain gender equality, thrive in a fair and just society, and experience security (Rao and Min 2018; UNDP 2022). Implications are discussed along four dimensions of well-being: basic material needs (SDGs 2, 6 and 7), good health (SDG 3), fair and just societies (SDGs 1 and 10), and human security (SDG 16). Gender equality (SDG 5) is treated as a cross-cutting issue where possible when discussing these dimensions. The two Transformation Pathways do not assume that these goals are being met but, in line with the underlying narratives, they are expected to improve.

9.4 Process of building the narratives for the target-seeking scenarios

Historically, most global environmental scenarios were exploratory, asking, "Which futures might unfold under specified conditions and what are their implications?" (IPBES 2016). However, over the past decades, narratives have been developed for both exploratory (van't Klooster and van Asselt 2006; Alcamo 2008; Kok et al. 2015; IPBES 2016) and target-seeking scenarios (Aguiar et al. 2020). Interest in developing sustainability-oriented target-seeking scenarios on the global level was catalysed by the United Nations 2030 Agenda and its SDGs, as well as the Paris Agreement (van Vuuren et al. 2015; Nakicenovic et al. 2018; Rogelj et al. 2018; Soergel et al. 2021). Global target-seeking scenarios represent alternative Transformation Pathways to reach such globally defined goals. GEO-7's target-seeking scenarios are focused on the transformation of five systems to achieve a set of seven internationally agreed goals related to the global environmental crises (**Table 9.1**). This section details the process of building the narratives for these scenarios.

Previous research suggests that narratives of target-seeking scenarios should capture multiple perspectives and key debates in society about sustainability, explore alternatives, and compare their outcomes, thereby fostering debate about possible pathways at multiple levels (Rosa et al. 2017; Aguiar et al. 2020; Pereira et al. 2020). Since an infinite number of possible alternative pathways exist in each system and their combinations, the crucial challenge is how to select which pathways to represent, and the level of detail required to represent them. As such, the design of the GEO-7 narratives used two steps. The first step defined the general characteristics and core assumptions about the narratives. Rooted on these general assumptions, the second step defined coherent sets of solutions for each system.

Step 1: General characteristics and core assumptions

The first step involved a literature review covering environmental scenario archetypes (Hunt et al. 2012; van Vuuren et al. 2012; IPBES 2016; Raskin and Swart 2020; Carlsen et al. 2024) and typologies of sustainability pathways (Stirling 2011; Geels et al. 2014; Luederitz et al. 2017; D'Amato 2021). Additionally, the review incorporated global target-seeking scenario narratives (van Vuuren et al. 2015; Rogelj et al. 2019; Soergel et al. 2021, 2024; Kok et al. 2023) and the multiple perspectives on nature proposed in the IPBES Nature Futures Framework (Pereira 2020). Most studies explore two or three alternative combinations of assumptions around selected dimensions. In general, these scenario studies differ in their emphasis on changing consumption patterns, the role of technology, the focus on global versus more localized approaches, and the way nature is valued.

Based on this review, the decision was made to represent two contrasting Transformation Pathways. The rationale for selecting only two alternative pathways is to facilitate an understanding of the core assumptions and solutions adopted in each system, as well as the analysis of the results. Both narratives affect production and consumption patterns, but from a different rationale, assuming different degrees of structural change in society. The narratives are archetypal, representing extremes, and are meant to facilitate exploration of the solution space of possible pathways. Creating a third pathway combining solutions from both pathways could create the wrong perception of a prescriptive best option and was therefore omitted. The two narratives represent different perspectives about what a sustainable future would look like.

The two narratives are:

- Behaviour-focused Transformation Pathway: This pathway envisions a deep transformation in society's values, beliefs and norms towards sufficiency, moving away from human materialism and consumerism (Luederitz et al. 2017; Raskin and Swart 2020). The importance of living in a more communal and symbiotic relationship with nature increases, largely inspired by the philosophies and ways of living of Indigenous Peoples and local communities, aligning with the "Nature as Culture" perspective proposed by the IPBES Nature Futures Frameworks (Pereira et al. 2020). Solutions to environmental and social problems are sought by combining multiple forms of knowledge, including mainstream science and the philosophies, practices and values of Indigenous Peoples and local communities, for example, in the food and environmental systems. This transformation entails structural changes in production and consumption systems, including a balance among global, regional and local markets, as well as a significant decrease in consumption – particularly in affluent countries – while the basic needs of humanity are met.

- Technology-focused Transformation Pathway: This pathway envisions massive investments in technology development aimed at achieving efficiency gains and green technologies to address the global environmental crises. It aligns with and expands upon the taking the Green Road scenario of the SSPs (O'Neill et al. 2017) and the Global Sustainability archetype (van Vuuren et al. 2012), envisioning an economically globalized, commodified, liberal and urbanized world. In this narrative, the overall economic system remains unchanged, but the well-regulated and appropriately priced green economy becomes the dominant paradigm, shifting consumption towards environmentally and socially responsible products (D'Amato 2021). Indigenous Peoples live in protected areas, receiving payment for ecosystem services and integrated into a well-functioning bioeconomy market. The dominant perspective about nature is aligned with the "Nature as Service" and "Nature for Nature" perspectives proposed by the IPBES Nature Futures Frameworks (Pereira et al. 2020).

Step 2: System-level solutions

The alternative solutions in each system reflect key debates about sustainability, relating to the general assumptions of each narrative and creating cohesive stories. For example, a food system debate focuses on how to reconcile food production and conservation (Godfray and Robinson 2015; Bennett 2017). The definition of solutions for the systems in each Transformation Pathway was based on the analysis of recent and similar scenario exercises (Kok et al. 2023; Soergel et al. 2024), refined through internal consultation with systems experts (Chapters 14–18) and regional experts (Chapter 20). A series of Indigenous Knowledge and local knowledge dialogues were held to help GEO-7 strengthen that perspective in the narratives (IK & LK Dialogues 2025). The resulting narratives for each Transformation Pathway and the debates they capture are presented in full detail in Section 11.2.

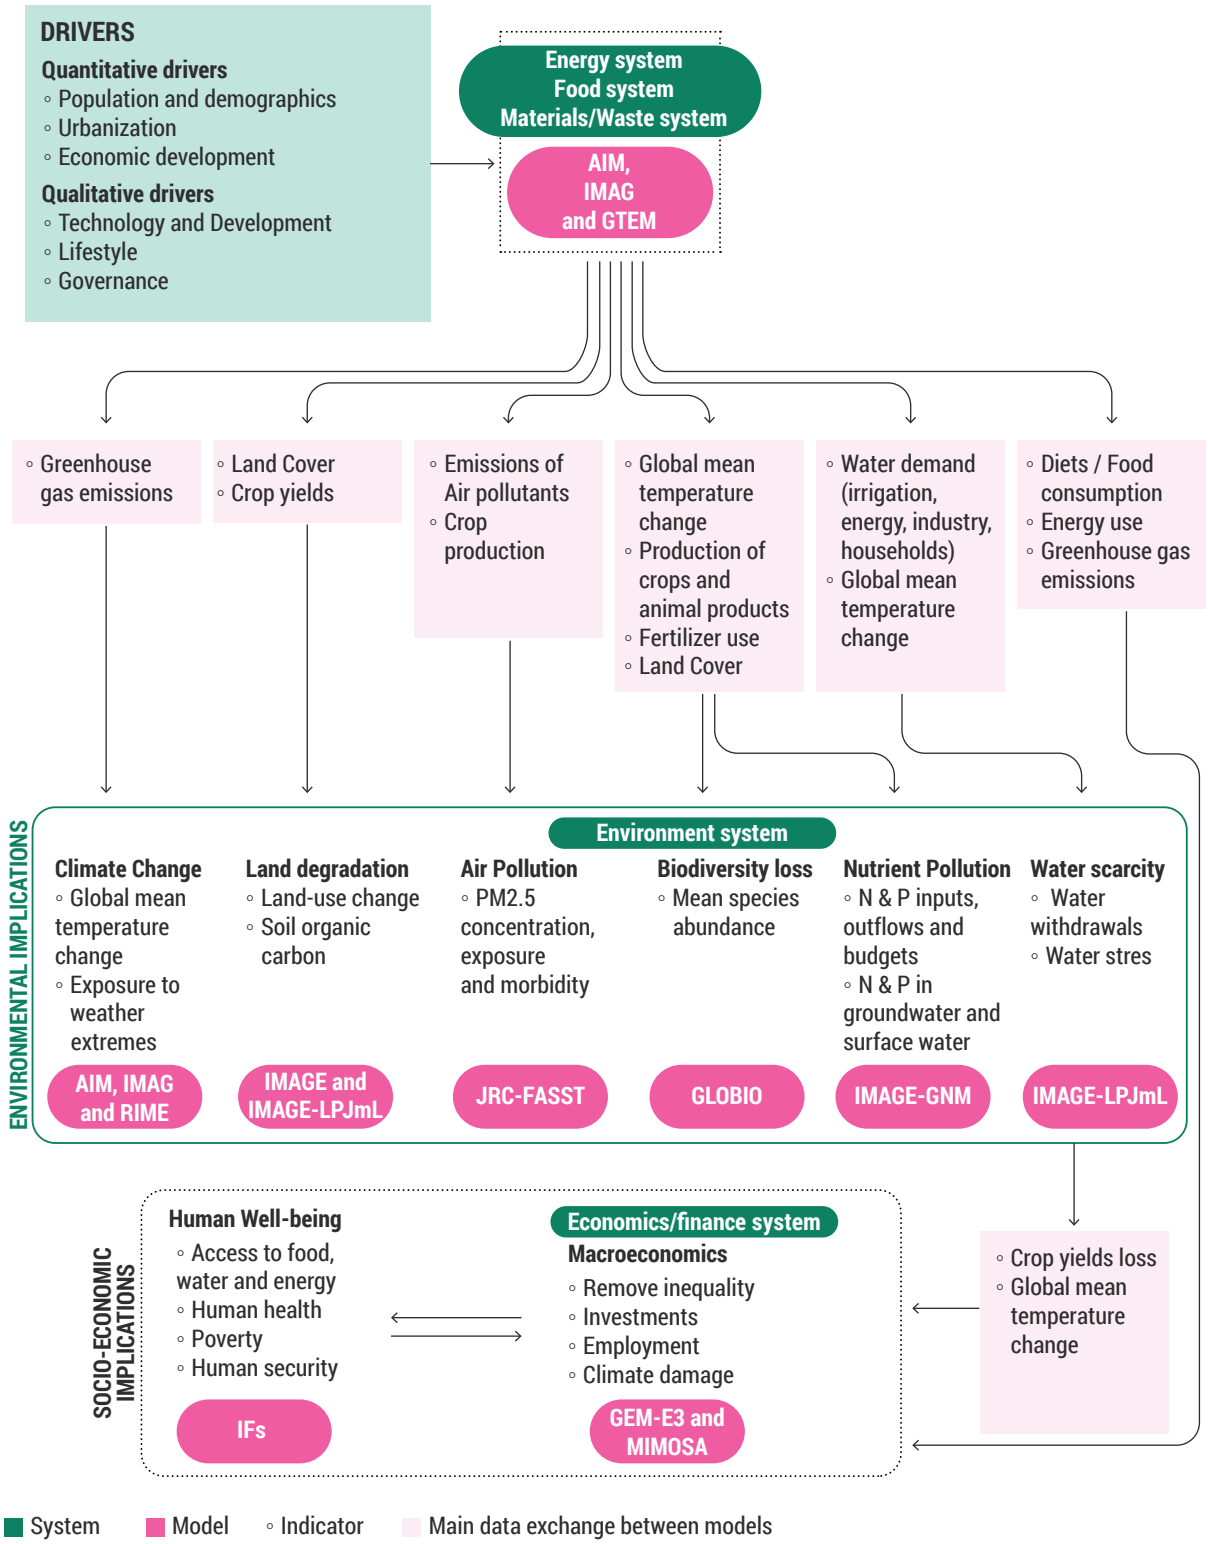
The narratives provide sufficient detail to support the scenario quantification process without duplicating content from subsequent chapters while providing key elements to enrich discussions about transformative pathways for specific income groupings (Chapter 19) and regions (Chapter 20). The Solution Pathways analysis of Chapters 14–18 further explores key solutions in the narratives, providing details about the necessary levers and actions, as well as the responsible actors, for implementing these transformations. Besides avoiding redundancy, this design aims to ensure consistency across GEO-7. The narratives are defined at the solution

level of the Goal-Solution-Lever framework proposed in Chapter 13. Appendix 11.A shows how the solutions combined in the narratives relate to the solutions discussed in the Solution Pathways of Chapters 14–18.

The importance and use of the scenario narratives

The two Transformation Pathways should not be taken in isolation. The future will likely be shaped by combinations of them – depending on the context and priorities of a given country or region – as well as by unexpected turns of events, technological disruptions and cultural resistance, among other influences. By comparing their outcomes, it is possible to identify the roles of different pressures and the dynamics that drive various synergies and trade-offs.

On their own, the narratives are key to fostering discussion and further analysis about alternative solutions in each system transformation and region. However, their core use in this report is to provide consistency in assumptions across the five systems for the process of quantification. The next step for building the quantitative scenarios is to translate the qualitative assumptions into numeric assumptions used by the models, such as altering "reduction in meat consumption" to "50 per cent reduction in relation to current values". During the whole process of narrative development, modellers were consulted to guarantee that the modelling parameters required to inform the quantification of the scenario could be extracted from the narratives. Appendix 11.A describes the modelling protocol in terms of a translation from qualitative description in the narratives to quantitative assumptions for the modelling.



9.5 Models used to quantify the scenarios

A suite of models is used to quantify the three scenarios. Together, these models address most of the relevant issues for assessing future developments in the five systems, global environmental crises, and related goals, as well as environmental and socioeconomic implications (**Figure 9.3**). The models are all well-established and validated in the literature and extensively used in scientific assessments, including earlier GEOs, reports from the IPCC (Byers et al. 2022; IPCC 2022), the Global Assessment Report on Biodiversity and Ecosystem Services (IPBES 2019), the Global Resources Outlook (UNEP 2024), the Global Land Outlooks (UNCCD 2017; UNCCD 2022) and the International Nitrogen Assessment (UNEP forthcoming). To create the integrated scenarios, these models are soft-linked, where the outputs of one model serve as input for other models (**Figure 9.3**). Model linking enhances the representation of the overall system by explicitly accounting for critical interdependencies and feedback between the component models. For a brief description of each model, its use in GEO-7, how they are interrelated, and further documentation and references, see Appendix 9.A.

Two Integrated Assessment Models – AIM (Fujimori et al. 2017) and IMAGE (Stehfest et al. 2014) – are central to the analyses, covering the energy and food systems, as well as climate change and land degradation. The results presented for the Current Trends scenario are based on AIM and for the two Transformation Pathways on IMAGE. This model choice is based on their respective strengths in representing the underlying dynamics. The AIM model is a hybrid computable general equilibrium model linked to an energy system optimization model. It is well-suited to capture the incremental, market-driven adjustments characteristic of continuing existing market and policy trends, including responses to established policy instruments. The IMAGE model is a hybrid system dynamics model with a detailed representation of technological and behavioural aspects of production and consumption. It is thereby well-suited to model the more systemic shifts in consumption, technology and policy that distinguish the Transformation Pathways. In addition, GTEM (Cai et al. 2015) was used for the projections of resource use for both scenario types. This model, together with IMAGE, was central to the resource use projections in the Global Resources Outlook (UNEP 2024). Together, the three models provide projections for the energy, food, and materials systems, as well as related pressures, such as emissions, land use, and resource exploitation.

Connected to the outcome from these three models, additional models are used to assess the environmental and socioeconomic implications. These models are used for all three scenarios. For the environmental implications, RIME (Werning et al. 2024; Byers et al. 2025) was used for climate change impacts, GLOBIO (Schipper et al. 2020) for biodiversity loss, IMAGE-GNM (Stehfest et al. 2014) for nutrient pollution, IMAGE-LPJmL (Schaphoff et al. 2018) for land degradation and water scarcity, and JRC-FASST (van Dingenen et al. 2018) for air pollution. For the socioeconomic implications, international futures (Hughes 2019) was used for human

Figure 9.3: Models used, their role in framework and connections to the other models

well-being, and GEM-E3 (Capros et al. 2013) and MIMOSA (van der Wijst et al. 2023) for economic effects.

The scenarios are implemented in the different models by adjusting appropriate parameters in line with the narratives. These include, for example, technology availability and learning rates, consumption patterns, protected areas, government and private spending, and food distribution. The key drivers – population, urbanization and gross domestic product – are exogenous to the models and similar for all three scenarios. They are based

on the SSP2 "middle-of-the-road" scenario (Chapter 10, Section 10.2). For the Transformation Pathways, the models are explicitly constrained to achieve the goals described in **Table 9.1**. The climate change goal is achieved by setting a budget on greenhouse gas emissions in line with the Paris Agreement, while the elimination of hunger, universal access to clean water and sanitation, and modern energy services are enforced via explicit food and energy access. Further adjustments were made to technology developments and lifestyle changes to ensure the achievement of the goals related to biodiversity loss and land degradation, and pollution and waste.

9.6 Challenges and limitations of the scenario approach

The applied methodology has its drawbacks and limitations, including the scope of scenarios, structural and parametric uncertainties, limited translation of narratives into model parameters, partial coverage of the global environmental crises, aggregation levels, and challenges in model integration. Appendix 9.A provides model descriptions, including a high-level overview of each model's limitations.

First, this assessment only evaluates three scenarios, which clearly does not cover the full spectrum of possible futures. To ameliorate this limitation, results are presented with ranges from established scenario databases, such as the IPCC AR6 scenarios database (Byers et al. 2022; IPCC 2022), and existing literature. This approach helps identify to what extent they belong to the uncertainty space of wider scenario exercises. It allows for an assessment of the consistency of the projections with widely recognized benchmarks, thereby reinforcing their validity.

Second, the models employed have several limitations due to structural and parametric uncertainties. Structural uncertainty can arise from an incomplete representation of relationships and processes of the represented system within the model framework, while parametric uncertainty stems from the imprecise nature of the parameter values used in these models (Pastor et al. 2020). For example, while average climate damages are included in the analysis, high-impact weather events, which may have disproportionate and cascading consequences, are only represented simplistically as understanding and appropriate modelling for these outcomes are not currently available (Raymond et al. 2020; Seneviratne et al. 2023). To address this caveat, an extra section on tipping points linked to the global environmental crises is added to Chapter 10, based on the literature. Furthermore, as the models only cover some of the feedback between environmental change and human activities, where relevant, Chapter 10 also draws on the broader literature to provide additional evidence of the consequences of the global environmental crises on human well-being projections.

Third, not all the details of the narratives developed for the target-seeking scenarios could be rendered into model parameters. For example, while the narratives do, to a certain extent, account for Indigenous Knowledge systems, this is not quantified in the models. Challenges include incorporating uncertainty, addressing bias, ensuring reliability, and aligning the scale of experiential knowledge with regional and global scales (Stern and Humphries 2022). For Indigenous Peoples, time is viewed as a cycle (Pereira et al. 2024), which significantly influences how the scenarios are interpreted. Furthermore, due to a techno-economic focus and normative cost-optimization in most models used, the two Transformation Pathways are heavily assessed in terms of their techno-economic feasibility; however, the cultural, political and social feasibilities of these pathways are not explicitly modelled. This lapse is partly addressed in Chapters 14–18, which discuss necessary levers, actions and actors for implementing the Transformation Pathways.

Fourth, due to the practical limitations of analytic capacity, the analysis focuses on a limited set of environmental challenges and related consequences. Pollution, for example, only focuses on ambient air pollution and freshwater nutrient pollution, while oceans and marine life are not addressed at all. These missing issues are partly covered in Part B State and Trends Chapters 3–6 of this report, but without a forward-looking perspective.

Fifth, the modelled scenarios are not appropriate for interpretation at the national or subnational level. The regional aggregation level in most models is typically restricted to large regions comprising country aggregates, which limits insights at more detailed spatial levels. Consequently, the results are only presented at the global scale, in Chapters 10 and 11, or for large, aggregated regions as in Chapters 19 and 20. For certain biophysical indicators, such as land and water use, air pollution, and biodiversity

Credit: CreativeNature_nl/Envato

loss, the analysis is conducted on a gridded level, and appropriate maps are presented.

Finally, while the data exchange between models ensures internal consistency, it can create possible biases in the results due to the limited selection of variables that are exchanged. Model linking also introduces various interconnection challenges. Fundamentally, models are built with differing purposes, system and regional boundaries, and underlying assumptions that complicate their integration. Bridging differences in temporal and spatial granularity, such as annual versus hourly data or global versus regional scope, requires careful aggregation and disaggregation techniques and introduces further assumptions (Belete et al. 2017). Again, this is partly addressed by presenting the results within ranges from established scenarios, databases and literature, where available.

9.7 Presentation of results

The analysis focuses on the timeline from 2020 to 2050, a period that is critical for understanding the consequences of Current Trends and policy actions on future environmental and socioeconomic conditions. This time frame aligns with many of the goals that the Transformation Pathways aim to achieve and is also a relevant time frame for policymaking. For climate change, the time frame is extended to 2100 to ensure consistency with the long-term climate target of the Paris Agreement.

The scenario results are presented and discussed in different ways throughout GEO-7. Chapter 10 uses the Current Trends scenario to discuss the extent to which the world is on track to achieve internationally agreed goals related to the global environmental crises and examines related environmental and socioeconomic consequences. Chapter 11 uses the two Transformation Pathways to discuss alternative routes to achieve these internationally agreed goals, including synergies and trade-offs across the goals and systems, as well as related challenges and opportunities. Both chapters focus on global-level results only.

The global Transformation Pathways offer a framework for addressing the global environmental crises. However, their practical effectiveness hinges on their adaptation to regional contexts through concrete, multidimensional targets and inclusive governance that address both technological and sociopolitical challenges (Wolff et al. 2024). These will be discussed in subsequent chapters. Chapters 14–18 discuss the necessary levers, actions and actors for implementing the Transformation Pathways for the five systems. Chapter 19 examines the Transformation Pathways for countries at various stages of economic development, highlighting the challenges, opportunities and best practices that support this transformation. Chapter 20 discusses the regional implications of the Current Trends scenario and the two Transformation Pathways. It presents and discusses the scenario results aggregated to the five UNEP-defined regions in combination with peer-reviewed literature, focusing on regional similarities and differences.

Appendix 9.1: Models used in global analysis (Chapters 10 and 11)

Model name	IMAGE 3.3 (Integrated Model to Assess the Global Environment)
Purpose of model	IMAGE is an integrated assessment modeling framework that simulates the environmental consequences of human activities worldwide. It represents interactions between society, the biosphere and the climate system to assess sustainability issues such as climate change, biodiversity and human well-being. The model can be used to explore the long-term pathways for future environmental and sustainable development problems as well as possible response strategies. It has representations of the energy, agriculture, land use, and climate systems. Typical outputs include projections of energy supply and demand, agricultural production, land use and land cover change, emissions of greenhouse gasses and other pollutants, and demand for water and material resources. The model is calibrated to datasets of energy supply and demand (International Energy Agency) and Agricultural production and land cover (Food and Agricultural Organisation). IMAGE participates in multiple model intercomparison projects covering energy, agriculture, emission scenarios, and sustainable development.
Solution mechanism	IMAGE is a hybrid systems dynamics model. It employs stylized optimization techniques when meeting climate targets. The model simulates the human and natural environment from 1971 to 2100, with the 1971-2018 period acting as a calibration and spin-up period. The model works on an annual timestep.
Main drivers / exogenous inputs	Population, economic activity are key exogenous drivers. Assumptions (across the food and energy systems) on technology availability and development, behavioural and lifestyle choices are also inputs. The model can incorporate land protection, energy, and other quantifiable policies.
Regional aggregation	IMAGE is a global model. Biophysical and land use are represented at a 0.5x0.5 degree grid, while socioeconomic processes are modelled on 26 regions. For details see the documentation.
Limitations	Model has a high level of aggregation concerning technologies, as well as social and economic dynamics. Thus, it may lack specific dynamics or insights concerning technological diffusion, bottlenecks, political/social constraints, and behavioural effects. Required changes in governance systems and consumer behaviour are enforced without assessing possible feedbacks.
Contribution to GEO7	**Use of results in GEO7** The IMAGE model is used to project the human-nature interaction of the Behavioural and Technology focused transformation Pathways. It provides the

	projections of the energy supply and demand, agricultural production, land use and land cover change, emissions of greenhouse gases and other pollutants, and demand for water. Its projections are presented in Chapter 12, particularly 12.3.1 and 12.3.2.
	Data received from other participating models None

Model name	**AIM 2.0 (Asia and the Pacific Integrated Model)**
Purpose of model	AIM is an integrated assessment model framework that primarily aims to give information to better understand climate change mitigation policy implications by simulating long-term human and relevant environmental systems. The model can also be used for the more general assessment of environmental consequences induced by human systems and policy changes, such as biodiversity and air pollution. Moreover, the socioeconomic implications associated with measures of environmental problems such as poverty, hunger and health. The AIM model consists of several independent models that represent economy, energy, land use, and household consumption. The core of the AIM is AIM-Hub (formerly named AIM/CGE), which represents the entire economic activities with detailed sectoral classifications as a computable general equilibrium model. This AIM-Hub model integrates the latter land-use and energy system model outputs and also provides the exogenous conditions for other models, such as regionally aggregated land use, income levels, etc. AIM-PLUM deals with spatial explicit land use and provides land-use change CO_2 emissions and bioenergy supply curve. Regarding energy representation, AIM-Technology (formerly named AIM/Enduse) is used, which represents greater resolution in energy technologies. The climate (radiative forcing and global mean temperature), atmospheric ($PM_{2.5}$ concentration, nitrogen depositions, etc.), and biodiversity conditions are computed by MAGICC, GEOS-Chem and AIM-Biodiversity.

Solution mechanism	• Energy system model AIM-Technology is optimization model and annually solved towards 2100. • Computable general equilibrium model AIM-Hub is CGE and annually solved towards 2100. • Land-use model AIM-PLUM is an optimization model and 10 years step towards 2100. • Other models are simulation-type models.
Main drivers / exogenous inputs	The main drivers of the overall AIM are population, income growth, demand preferences (such as dietary preferences), technological progress in energy, agriculture and the general economy, and inequality conditions. Most of the drivers are built upon the Share Socioeconomic Pathways assumptions mostly described in Fujimori *et al.* (2017).
Regional aggregation	• The AIM-Hub geographical resolution is 17 socioeconomic regions. • The AIM-Technology geographical resolution is 31 socioeconomic regions. • The AIM-PLUM and AIM-Biodiversity geographical resolution is 0.5 degrees. • GEOS-Chem is normally run by 4 x 5 degrees.
Limitations	Representation in energy technology is very detailed, with more than 500 in total from both sides of demand and supply. However, behavioural representation is not well detailed. The land use and agricultural representation in regional aggregates could be realistic to an extent, but spatial distribution is resolved under optimization, which may include some differences from reality. In that sense, the interpretation of the spatial land use map would need special consideration.
Contribution to GEO7	**Use of results in GEO7** The AIM model is used to project the human–nature interaction of the Current Trends pathway. It provides the projections of the energy supply and demand, agricultural production, land use and land cover change, emissions of greenhouse gases and other pollutants, and demand for water. **Data received from other participating models** Changes in GDP projections from the GEM-E3 model were input into AIM

Contribution to Global Environmental Assessments	IPCC AR6 WGIII report

Model name	GTEM-Resource_2023 (Global Trade and Environment Model with a Resource module)
Purpose of model	GTEM is a global dynamic computable general equilibrium (CGE) model. It is a hybrid model that combines the top-down macroeconomic representation of a CGE model with the bottom-up engineering details of energy production along with a representation of greenhouse gas (GHG) emissions by economic sector. With a module of accounting for the physical flows of resources and materials built-in GTEM, GTEM-Resource is able to provide the global and regional demand for various categories of materials and resources that are consistent with the UN IRP database. By adding the module, its outputs can also be used to compute and project the material footprints into the future. In this version, the model baseline is calibrated to the SSP2 GDP and population projections, and the baseline global primary energy production and energy mix is calibrated to the STEPS scenario from the International Agency of Energy 's World Energy Outlook (WEO) 2021. The typical outputs from the model include GDP, GHG emissions, material uses (DE, DMC, etc.) by 61 categories, sector outputs, household demand by commodity, commodity prices, and international trade flows by region. GTEM can also integrate with GLOBIOM to provide LULUCF emissions and land use change.
Solution mechanism	GTEM is a recursive dynamic CGE model. It is solved on a yearly basis. In this version, the simulation goes to 2060, but it can be solved for 2100 for long-term purposes.
Main drivers / exogenous inputs	The population is exogenous input; the GDP in the *Current Trends* scenario is exogenous input, while the GDP in the Transformation Pathway scenario is endogenous output. The various energy efficiencies and material efficiencies are exogenous inputs. In the Transformation Pathway scenario, various policy shocks, technological changes and behavioural changes are exogenous inputs.
Regional aggregation	In this version of GTEM-Resource, the model has 34 regions, of which there are 28 individual countries covering most of the important countries in the world in terms of economic development and resource use.
Limitations	The model assumes homogenous households and therefore the behavioral changes across different income groups within a region are homogenous, which may cause some bias in the results. The model does not have explicit representation of biofuels, therefore results on biofuels are not available.
Contribution to GEO7	**Use of results in GEO7** GTEM-Resource provides the GEO-7 report with results on economy-wide material use on both global and regional levels. **Data received from other participating models** GTEM-Resource receives the GHG emissions pathways from

	IMAGE in the Behaviour-focused and Technology-focused Transformation Pathways.

Contribution to Global Environmental Assessments	UNEP-IRP Global Resource Outlook 2019 and 2024

Model name	**JRC-FASST (JRC-FAst Scenario Screening Tool)**
Purpose of model	JRC-FASST is a global reduced-form air quality source–receptor model that has been designed to compute ambient pollutant concentrations as well as a broad range of pollutant-related impacts on human health, agricultural crop production, and short-lived pollutant climate metrics, taking as input annual pollutant emission data aggregated at the national or regional level. The annual average concentrations of air pollutants generated by JRC-FASST are tested by comparison with the Chemical Transport Model that was used to develop the emission-concentration sensitivities (see below). In addition, the historical years in the base-case scenario are validated by comparison with other models and with measurements.
Solution mechanism	JRC-FASST is based on linearized emission-concentration sensitivities derived with a full chemistry transport model (EMEP GLOBAL) and EDGAR emissions of atmospheric pollutants (https://edgar.jrc.ec.europa.eu).
Main drivers / exogenous inputs	The main exogenous input is the annual emissions of air pollutant precursors SO2, NOx, NH3, BC, OC, non-methane volatile organic carbon (NMVOC), CO, and CH4 in 76 source regions covering the entire globe. Population, all-cause and cause-specific mortality are used to estimate the share attributable to air pollution. Specific crop production and crop growing seasons are used to estimate the annual yield losses.
Regional aggregation	The model generates a gridded air pollution concentration output at 0.5 x 0.5 degree resolution. The impacts (health outcomes, crops, vegetation) are typically provided at the country level worldwide.

Limitations	The applied methodology is based on a reduced form model which reproduces the results of a full chemistry and transport model (EMEP) with a <5% uncertainty. The model adopts a simplified approach to estimate future climate-chemistry interactions.
Contribution to GEO7	**Use of results in GEO7** JRC-FASST is used to report the concentration of pollutants ($PM_{2.5}$, ozone), exposure indicators for human population and vegetation, number and share of population exposed to high pollution levels ($PM_{2.5}$ > 25 µg/m^3), mortality and morbidity attributable air pollution, and crop yield losses attributable to air pollution. **Data received from other participating models** Projected emissions of air pollutants and crop production are provided by AIM and IMAGE.

Contribution to Global Environmental Assessments	IPCC AR6 WGI report

Model name	**GLOBIO 4.0 (Global Biodiversity Model for Policy Support)**
Purpose of model	The GLOBIO model quantifies local terrestrial biodiversity intactness, expressed as the Mean Species Abundance (MSA) indicator as a function of climate change, atmospheric nitrogen deposition, land use, roads, and hunting (tropical regions). The impact of habitat fragmentation, resulting from both land use and roads, is also included. The impact of the different pressures on MSA is quantified for plants and vertebrates separately and then combined into one overall MSA value. In this study, we applied version 4 of the GLOBIO model.

Solution mechanism	GLOBIO 4.0 is based pressure-impact relationships established through meta-analytical approaches based on empirical data in combination with data on pressure levels. Regression equations for each independent pressure factor are estimated using generalized linear mixed models.
Main drivers / exogenous inputs	Population changes and economic activity are key exogenous factors driving land use change, climate change and nitrogen pollution. These pressures are exogenous inputs for the GLOBIO model. Additional assumptions on nature protection and the level of protection, land use configuration and the level of infrastructure use can be adapted to address scenario assumptions and policies. The ESA-CCI land cover product is used as the basis for land use change calculations (ESA 2017). Global road data are from the GRIP database (Meijer et al. 2018). To quantify hunting pressure in tropical regions, the distance to settlements is required. We obtained locations of settlements from OpenStreetMap (http://download.geofabrik.de), the Humanitarian Data Exchange (www.data.humdata.org) and national databases.
Regional aggregation	GLOBIO is a global model. Biodiversity intactness is calculated using downscaled land use information at a resolution of 10 arcseconds. Aggregation of results can be calculated at all coarser resolutions.
Limitations	The model parameters are data-driven and data are derived from published scientific literature and other open sources. The distribution of available data are, therefore, unequally distributed. Major data gaps are from Europe, for a lack of pristine ecosystems, and eastern Asia, for a lack of accessible literature.
Contribution to GEO7	**Use of results in GEO7** The GLOBIO model is used to assess biodiversity intactness changes as projected in the baseline scenario and in the Transformation Pathways. **Data received from other participating models** Changes in land use, climate and nitrogen deposition are derived for the IMAGE model.
Key Reference(s)	Alkemade, R., Van Oorschot, M., Miles, L., Nellemann, C., Bakkenes, M., & Ten Brink, B. Contribution to Global Environmental Assessments	CBD Global Biodiversity Outlooks 2–5 , IPBES regional and global assessments, UNEP GEO-4, OECD Environmental Outlooks, and UNCCD Global Land Outlook 1 and 2.

Model name	IMAGE-GNM (Integrated Model to Assess the Global Environment – Global Nutrient Model)
Purpose of model	IMAGE-GNM is a globally distributed, spatially explicit model using hydrology from PCRGLOBWB as the basis for describing nitrogen (N) and phosphorus (P) delivery to surface water, transport and in-stream retention in rivers, lakes and reservoirs. IMAGE-GNM is hard-linked to the integrated assessment modelling framework IMAGE. IMAGE-GNM uses the land use information and nitrogen deposition from IMAGE and the associated agricultural production (grass, crop and animal production) to estimate the N and P fertilizer use for cropland and grassland. Human protein consumption is used to estimate the delivery of human and industrial sewage to rivers. Also, the delivery of nutrients from natural land to the rivers is estimated. The load is transported by the rivers to the coastal seas, taking into account the in-stream loss processes in the river. The model can be used to explore the long-term pathways for future environmental and sustainable development problems as well as possible response strategies. Typical outputs include projections of nutrient delivery to the rivers and the export of nutrients to the coastal seas, including the distribution of different nutrient sources.
Solution mechanism	IMAGE is a globally, distributed, spatially explicit model. The model works on an annual timestep but takes into account the historical loads. The model starts in 1900. This is needed to incorporate the storage of nitrogen in groundwater and the storage of phosphorus in the soil pools. The model is validated on a long-term time series of observed N and P concentrations in several river basins (e.g. Mississippi, Rhine, Meuse, Yangtze).
Main drivers / exogenous inputs	Next to the data that is used from IMAGE, there are other assumptions that are not provided by the IMAGE model. Nitrogen Efficiency Use (NUE) is used as the main driver to calculate future N fertilizer use. The P fertilizer use is determined by the P content of the soil and the P availability for the plant. The recycling of manure and soil conservation in the agricultural sector are policy options which can lead to a more sustainable sector. Assumptions on the number of people connected to a sewage system and the efficiency of the sewage treatment plants can improve the population's health and water quality. The production of aquaculture is another direct input of nutrients in the rivers and is one of the scenario assumptions.
Regional aggregation	IMAGE-GNM is a global model. Biophysical and land use are represented at a 0.5 x 0.5 degree grid.
Limitations	The IMAGE-GNM model uses land use information from the IMAGE model. This land use is consistent with the regional statistics but could deviate on a national scale. For example, the combination of total fertilizer use on a national scale with the IMAGE land use data could give high results in kg/ha. The total fertilizer is preserved on preserved a national level.

Contribution to GEO7	**Use of results in GEO7** The IMAGE-GNM model is used to project N and P pollution of groundwater and surface water. **Data received from other participating models** IMAGE-GNM is hard-linked to the IMAGE model, where it receives information concerning land cover, agricultural production (crops and animals), nitrogen deposition, population and human protein consumption.

Contribution to Global Environmental Assessments	OECD Environmental Outlook to 2050, UNCCD Global Land Outlook 1 and 2, INMS (Integral Nitrogen Management System), World Water Quality Assessment

Model name	**LPJmL 4: Lund Potsdam Jena managed Land**
Purpose of model	LPJmL is a global gridded model that describes the coupled carbon and water cycles. It simulates natural vegetation growth, crop growth and hydrology. The human impacts on the hydrological cycle, such as irrigation water withdrawals, other water withdrawals, water supply and the operation of large dams and reservoirs, are included. The effect of water limitation on vegetation growth is simulated. This makes LPJmL a very suitable tool to study the interactions between water and food production. The model is validated against discharge measurements, carbon fluxes, and vegetation patterns and calibrated against crop yields at country level.
Solution mechanism	LPJml is a simulation model based on a representation of biophysical processes. It can be run stand-alone or fully coupled to IMAGE. Daily time step, the time horizon is usually 2100, depending on the time horizon of input data.
Main drivers / exogenous inputs	In GEO, LPJmL is run fully coupled to IMAGE. This means that it gets annually gridded data on climate, non-agricultural water use, land use from IMAGE and sends back annual info on crop yields, agricultural water withdrawals, water availability, natural vegetation growth and the carbon cycle to IMAGE.
Regional aggregation	The LPJmL model represents all biophysical processes at 0.5 x 0.5 degree grid, but water balances are calculated with subgrid variability. Crop management parameters are calibrated at the country level. The model output can subsequently be aggregated to any regional level.

Limitations	Crop yield growth is impacted by climate change through changing temperature, precipitation and CO_2 fertilization, but other processes that affect yields are not represented, such as flooding and waterlogging, and pests and diseases. The hydrological cycle is represented in a simplified way, for example, lakes and lateral flow of deep groundwater is not taken into account.
Contribution to GEO7	**Use of results in GEO7** LPJmL is run fully coupled to IMAGE. In GEO-7 the model will be used in the Outlook chapters, both for the Current Trends as well as the Behaviour-focused and Technology-focused Transformation Pathways. The effects of current trends and measures in both pathways on green and blue water use and water scarcity will be assessed. **Data received from other participating models** Because LPJmL will be run fully coupled to IMAGE, it does not require any direct additional inputs from other participating models.

Contribution to Global Environmental Assessments	OECD Environmental Outlook, UNCCD Global Land Outlook 1 and 2.

Model name	**International Futures (IFs) v 8.26.2**
Purpose of model	International Futures (IFs) is an integrated quantitative tool that forecasts hundreds of variables for 188 countries over long time horizons. The key submodules represented include agriculture, conflict, climate, demographics, economics, education, energy, gender, governance, health, infrastructure, international politics, and technology. The model is a hybrid structure drawing upon a variety of traditions that include a recursive dynamic computable general equilibrium tool with a full social accounting matrix, representation of income inequality and poverty across multiple thresholds by age and sex, partial equilibrium models of agriculture and energy, a cohort component demographic

	model, a proximate-distal driver model of mortality by age, sex across 15 disease categories, probabilistic models of conflict, and a fully elaborated schooling, attainment and education quality model across levels and sex. The underlying code is open source, and the user interface allows analysts to create their own scenarios by adjusting parameters.
Solution mechanism	The model "solves" each year, though it does not achieve equilibrium of supply and demand across any system that represents supply/demand. Instead, the model allows stocks of inventory to carry forward, dynamically "chasing" equilibrium across time.
Main drivers / exogenous inputs	The model has very few exogenous inputs, and population and economic development are endogenously computed for each country across time. The model creates a "base case" or "current path" scenario that is the most likely development trajectory across all indicators and is used as a basis for analysis and scenarios. This scenario generally behaves somewhere between SSP2 and SSP3 (depending on the SSPs and IFs version) and reflects a future development trajectory where most SDG goals are not met by mid-century, and the climate pathway is between RCP4.5 and RCP6.0 in the future.
Regional aggregation	IFs is global and represents development for 188 countries. The inclusion criteria tend to be global data availability and population size above 100,000 individuals, irrespective of sovereign status.
Limitations	The limits of the model are vast. The representation of greenhouse gas emissions in particular and natural systems in general are simplistic and not state-of-the-art. The unit of analysis deployed is geographically fixed, and the model does not have the ability to disaggregate and look at within-country factors. The representation of energy and agricultural systems is not as granular as many other tools in this area. Understanding the forecasting accuracy of the tool is also a significant challenge, and historical validation helps us understand strengths and weaknesses, but the future will be characterized by a different set of factors than the past.
Contribution to GEO7	**Use of results in GEO7** IFs is used to track a reference pathway for human and social development and then to operationalize the transformation pathways using exogenous inputs from IMAGE and JRC-FASST in addition to assumptions related to the distribution of calories, electricity access, and water and sanitation access. The variables presented in GEO from IFs include water and sanitation, electrification, the probability of civil war onset, poverty, and health outcomes across various categories disaggregated by sex. The tool was also used to explain the additional policy steps needed to achieve some of the core human development results, highlighting the complexity of achieving these transformation pathways. Specifically, IFs takes SSP2 pathways for population and the Gini coefficient for income inequality for the reference pathway and SSP1 for population and Gini coefficient for income inequality for the Transformation Pathways. For the Transformation Pathways, the model forces the elimination of poor access to electricity, water, sanitation, and undernutrition. For all GEO-7 scenarios, the model takes projections from IMAGE for agricultural production, land use,

	agricultural yield change, carbon emissions, traditional cookstoves, and total energy production, as well as renewable energy production. In addition, it takes global projections from FASST for air pollution over $PM_{2.5}$. **Data received from other participating models** Data was received from IMAGE concerning projections of the energy and land use systems, including the use of traditional cooking fuels. JCR-FASST provided projections of a population exposed to ambient particulate matter.

Contribution to Global Environmental Assessments	UNEP GEO-4

Model name	**GEM-E3 (General Equilibrium Model for Economy, Energy and Environment)**
Purpose of model	GEM-E3 represents the operation of the economic system and its interaction with energy and environment. It is a global large-scale applied Computable General Equilibrium (CGE) Model that represents all economies simultaneously linking them with endogenous bilateral trade flows (using the Armington assumption). The key innovations of the model relate to the explicit representation of the financial sector, semi-endogenous dynamics based on R&D-induced technical progress and knowledge spillovers, the representation of multiple households, unemployment in the labour market and endogenous formation of labour skills. The model is calibrated to a wide range of datasets comprising Input-Output (IO) tables, financial accounting matrices, institutional transactions, energy balances, GHG inventories, bilateral trade matrices, investment matrices and household budget surveys. Particular focus is placed on the representation of the energy system where specialized bottom-up modules of the power generation, buildings and transport sectors have been developed. The model is founded on rigorous and

	sound microeconomic theory allowing it to study in a consistent framework the interlinkages of the economic sectors and to decompose the impacts of policies to their key driving factors.
Solution mechanism	GEM-E3 is recursive dynamic CGE coupled with a forward-looking expectations mechanism and produces projections of the economic and energy systems until 2100 (the base year is 2021, the first simulation year is 2025 and then five-year time steps until 2100). The model optimizes firms and household behaviour and ensures macroeconomic closure at the global level through the interest rate (alternative closures apply).
Main drivers / exogenous inputs	The key exogenous inputs to the model are: i) Technical Progress/ Productivity (partial exogenous – endogenous R&D and learning can apply); ii) Population, Active Population and Participation Rate; iii) Long Term Expectations on Capital Accumulation; iv) International Energy Prices; v) Energy and Climate policies; vi) Technology Costs, especially for low-carbon technologies.
Regional aggregation	The model is global and aggregates the world in 46 countries/regions. All EU Member states are represented individually, all G-20 countries individually, and main energy-producing countries individually. The model aggregates the economy in 51 economic activities, with a focus on energy supply (coal, oil, gas, electricity, biofuels, renewable energy) and energy-intensive industries (steel, cement and non-metallic minerals, chemicals, paper and pulp).
Limitations	The model does not capture all physical climate impacts and extreme events, and this may lead to an underestimation of the cost of climate change
Contribution to GEO7	**Use of results in GEO7** The GEM-E3 model is used to assess the socioeconomic impacts of the Behaviour-focused and Technology-focused Transformation Pathways. It provides projections of the GDP and sectoral production, employment and unemployment rate by scenario until 2100. **Data received from other participating models** The energy system (fuel mix per industry, power generation mix, fuel mix in transport) is calibrated to the output of IMAGE. The baseline GDP projections are calibrated to the AIM model. Morbidity and labour productivity effects are taken from IFs and impact on land use from the IMAGE model.

Contribution to Global Environmental Assessments	IPCC AR6 WGIII Report

Model name	**RIME (Rapid Impact Model Emulator)**
Purpose of model	RIME enables the rapid assessment of climate impact indicators using global warming level approaches. For a given input global warming scenario, RIME uses multidimensional interpolation methods, primarily based on global warming levels, to produce a suite of climate impact indicators, in both global gridded formats as well as aggregated to regions like countries or river basins. Depending on the input data available, it can be used for a suite of climate impact drivers including temperature, precipitation and hydrological indicators, as well as extending to assess exposure to impacts, for example of population, land area or GDP.
Solution mechanism	RIME's current implementation is deterministic.
Main drivers / exogenous inputs	As inputs, RIME requires: • the global mean surface temperature trajectory through time, e.g. from a simple climate model like FaIR or MAGICC • an input impacts database with data stored by global warming levels, e.g. Werning et al. (2024)
Regional aggregation	RIME is flexible in region aggregation, which depends only on the resolution of input data. Typically: • For gridded data, 0.5 x 0.5 degree gridded data is used, the output being the same • For regional data, RIME has used UNEP 5-region + World data as input and output. Other aggregations, e.g. country, river basin, and IPCC region, are possible but not used here.
Limitations	The pattern-scaling approach means that natural climate variability cannot be captured. Thus, the impact estimates are to be interpreted as a snapshot indicator representative of that global warming level, and indicative of the long-term change. The data should also be used with caution for scenarios exceeding 3°C global mean temperature or scenarios in scenarios with post-peak temperature reductions >0.2°C.
Contribution to GEO7	**Use of results in GEO7** In the case of GEO-7, greenhouse gas emissions from the integrated assessment models IMAGE and AIM are run through MAGICC to provide global mean surface temperature, which is used as input into RIME. The results presented show the regional changes by indicator between 2020 and 2050 for the transformation and reference scenarios, as well as estimates of the population exposed to each climate impact indicator.

	Data received from other participating models Global Mean Temperature timeseries from the IMAGE and AIM models.

Contribution to Global Environmental Assessments	None

Model name	**MIMOSA (Integrated Assessment Model for Cost-Benefit Analysis)**
Purpose of model	MIMOSA is an Integrated Assessment Model (IAM) part of the IMAGE family, with 26 regions covering the whole world. It is a relatively simple Cost-Benefit IAM that still covers the relevant technological and socioeconomic dynamics. The climate impacts are calculated using state-of-the-art COACCH damage functions, and the mitigation costs have been directly calibrated to the IPCC AR6 WGIII database. Its main purpose is to calculate the economic impacts of climate change, costs of inaction, benefit-cost ratios of climate policy, and perform cost-benefit analysis of global climate policy.
Solution mechanism	MIMOSA is a global optimization model that tries to maximize the net present value of welfare. When emission pathways are not imposed beforehand, the model distributes mitigation efforts across regions and time while taking into account each region's marginal mitigation costs, climate damages, and per capita income. The model works on 5-year timesteps from 2020 to 2150, but the results are focused on the period 2020 to 2100 since the years 2100 to 2150 are used to avoid end-of-horizon problems.
Main drivers / exogenous inputs	Population, baseline emissions, technological assumptions and baseline carbon intensity are exogenous and dependent on SSP. The key parameters

	are discount factor, level of climate impacts (in percentiles of literature range), climate sensitivity (TCRE, in percentiles of AR6 range), SSP, and mitigation cost level (in percentiles of AR6 range).
Regional aggregation	MIMOSA is a global model running on the same 26 regions as IMAGE.
Limitations	MIMOSA uses a simple linear relation between cumulative CO_2 emissions and temperature. While this is shown to yield better results than a slightly more detailed 2-box-climate module, this does introduce uncertainty since non-CO_2 gases are not explicitly modelled. Also, the linear (TCRE) relation between cumulative emissions and temperature might not be as accurate after a temperature peak, when emissions become net negative.
Contribution to GEO7	**Use of results in GEO7** MIMOSA is used to calculate the economic impacts of climate change in both transformation pathways and the costs of inaction in the no-policy scenario. **Data received from other participating models** Baseline regional GDP (without mitigation costs or climate impacts) and regional population are used from the IMAGE reference scenario. For the Current Trends Scenario, global emissions are used from AIM, while for the two Transformation Pathway Scenarios, the global emissions are obtained from the IMAGE runs.

Contribution to Global Environmental Assessments	IPCC AR6 WGIII Report

Models used in Regional Analysis (Chapter 21)

Model name	**T21-iSDG® (Integrated Sustainable Development Goal model that evolved from the Threshold 21 model)**
Purpose of model	The iSDG is a modelling framework of the Millennium Institute (MI). The model is designed to support integrated planning and policy analysis for sustainable development at the national level. It allows for scenario analysis, enabling users to

	explore different policy options and evaluate their effects on various sustainability indicators. The iSDG model includes 30 modules that span social, economic, and environmental sectors and includes 78 indicators and relevant policies across all 17 UN SDGs. Additional indicators can be included in the process of customization to a country's characteristics and analytical needs. Model validation is embedded in the broader implementation process. Structural validation tests involve direct verification of the assumptions made in the model structure and parameters. Behavioural validation tests involve the assessment of the model's ability to replicate the historical behaviour through means of calibration. The calibration process evaluates the goodness-of-fit for the model application through statistical indicators.
Solution mechanism	The iSDG model is built using the system dynamics methodology. Depending on the dynamics of interest, it typically simulates the dynamics from 2000 to 2030/2050, with the 2000–present time used for calibration. The model commonly simulates dynamics on a quarterly or annual timestep, with time units at a monthly or yearly scale. The standard calibration process makes use of the Stella® optimization function to obtain a reasonable calibration rapidly.
Main drivers / exogenous inputs	iSDG's fundamental approach is to endogenously represent variables that are considered an essential part of the development mechanisms under analysis. For example, GDP, population, and the demand and supply of natural resources and their main determinants are endogenously calculated. Variables that have an important influence on the issues analysed, but are only weakly influenced by the issues analysed, are exogenously represented. For example, rain cycles, the grants received, or the exchange rate are exogenously determined. Since the focus of iSDG is on long-term development issues, inflation and interest rates are also exogenously represented. For specific country applications, where supported by evidence, these variables can be made endogenous in the model.
Regional aggregation	The base iSDG model is structured as a national model, and, from a geographic perspective, data are aggregated at the national level. The main social, economic and environmental variables are further broken down into subcomponents. For example, population is divided into 101 age cohorts and two genders. Customization of the level of aggregation of iSDG is possible. In this instance, national dynamics can be disaggregated by degree of remoteness or at a regional scale, though this is highly context specific and dependent on data availability. Full details on the level of aggregation are provided in the model documentation.
Limitations	The model's results inherently embed a high degree of uncertainty, being long-term in nature (a large variety of unforeseeable changes can take place) and broad in scope (including a large number of parameters with uncertain future values). The iSDG model is not intended to substitute short-term or sector-specific models.
Contribution to GEO7	**Use of results in GEO7** Outputs from the iSDG model are included in Chapter 20 (Regional similarities and differences) to provide an example of the use of the iSDG to support national development in sub-Saharan Africa. **Data received from other participating models** The iSDG model does not receive data from the models currently used in the

	GEO-7 assessment, though future work can incorporate evaluating the Solution Pathways scenarios for different country contexts. iSDG data is typically sourced from national databases and documents or may be sourced from the government and relevant stakeholders. In the absence of national datasets, global data sources can also be used (e.g. World Bank, IMF, IEA, FAO, UNDP and UNSTATs).

Contribution to Global Environmental Assessments	UNEP GEO-5

Model name	**IMED (Integrated Model of Energy, Environment and Economy for Sustainable Development)**
Purpose of model	The IMED integrated assessment model addresses key scientific challenges and policy imperatives crucial for facilitating green and low-carbon transitions in alignment with national and global sustainability objectives. Central to its investigations are questions surrounding the mitigation costs associated with ambitious climate targets and their co-benefits, particularly in terms of improvements in air pollution, human health, and resource efficiency. Outputs of the IMED model include projections of energy supply and demand, emissions of greenhouse gases and other air pollutants, and demand for various material resources like industrial water use. IMED model can also be connected with the GLOBIOM model from IIASA to get the outputs about land-use change. The model is calibrated to national and global Input-Output tables, air pollutant emissions (multi-resolution Emission Inventory for China), and energy supply and demand (International Energy Agency).
Solution mechanism	The IMED model includes several interconnected submodels. The IMED|CGE is a general equilibrium model solved by Mathematical Programming System for General Equilibrium under the General Algebraic Modeling System (GAMS/MPSGE) at a one-year time step. IMED|TEC model draws on the energy system cost minimization based on linear optimization programming. These two models could be combined with the IMED|HEL model for human health impact assessment and GLOBIOM from IIASA for

	land-use change assessment, forming the core of the entire IMED model system.
Main drivers / exogenous inputs	Exogenous inputs of the IMED model include population and economic activity, the cost of technology in some important sectors, land use data and food production yields. The main drivers are the energy and resource-intensive sectors, future energy services, and low-carbon pathways.
Regional aggregation	The IMED/CGE model includes 31 Chinese provinces and 26 global regions. The IMED/TEC model includes 31 Chinese provinces and the IMED/HEL model operates at a global 0.5 x 0.5 degree grid.
Limitations	Currently, the IMED framework primarily integrates Computable General Equilibrium (CGE) modeling and energy system models centered on economic indicators and energy flows. However, it lacks dedicated modules and foundational datasets for projecting material demands. The absence of algorithms focused on resource and material flows undermines the system's ability to evaluate future policies comprehensively. This limitation not only weakens the accuracy of energy and emission pathway estimations in physical terms, but also constrains the assessment of resource circulation strategies and demand-side management policies.
Contribution to GEO7	**Use of results in GEO7** The IMED model is used for analyzing the Transformation Pathways to reach carbon neutrality by 2060 for China in the national case study box, revealing the subregional and rural–urban differences regarding the water-energy-food nexus and consequently different impacts on air pollution, human health and land use. **Data received from other participating models** GDP projections could be compared with the GEM-E3 model, and air pollutant concentration data could be obtained from the FASST model to calculate health impacts.

Chapter summary

Credit: SeanPavone/Envato

Current socioeconomic development patterns and prevailing approaches to valuing land and nature are failing to meet many internationally agreed environmental goals (*well established*). This chapter discusses future environmental and socioeconomic developments if the current development trajectories continue by presenting and discussing the *GEO-7 Current Trends Scenario,* developed specifically for the seventh Global Environment Outlook (GEO-7) report. This scenario follows historical trajectories of social, economic, and technological developments. Under this scenario, most environmental pressures are projected to intensify, including further rising greenhouse gas (GHG) emissions, continuing land-use change, and intensifying resource exploitation. Major drivers of these trends include population growth, increasing urbanization, further economic growth, and resource-intensive lifestyles. Consequently, negative trends in the global environmental crises of climate change, biodiversity loss, land degradation and desertification, and pollution and waste are projected to worsen through 2050 {10.2, 10.3, 10.4}.

In the energy system, rising energy demand and persistent dependence on fossil fuels drive increases in GHG emissions (*well established*). Despite improvements in energy efficiency, increasing demand leads to an estimated 25 per cent rise in primary energy use between 2020 and 2050. While the share of renewable energy in total energy production increases, by 2050 fossil fuels still dominate the overall energy mix, sustaining high GHG emissions. Air pollution levels gradually decrease but remain high {10.3.1, 10.4.1, 10.4.2}.

In the food system, population growth and shifting preferences to more animal-based foods drive agricultural land expansion, rising GHG emissions, as well as increasing air and nutrient pollution (*well established*). Meeting the growing food demand of a larger, wealthier population with increasing shares of animal-based foods will require a roughly 50 per cent increase in crop production between 2020 and 2050. This demand outpaces projected yield gains, leading to further expansion of agricultural land. Other

environmental pressures include increasing GHG and ammonia emissions linked to crop and livestock production and fertilizer application {10.3.2, 10.4.1, 10.4.2, 10.4.3}.

In the resources system, population growth and economic development are key drivers of a sharp increase in global materials extraction (*well established*). The extraction of material resources, including biomass, fossil fuels, minerals and metals, is projected to rise by 70 per cent between 2020 and 2050, peaking around mid-century. The largest increase comes from non-metallic minerals, primarily driven by rapid increases in infrastructure expansion and construction in low- and middle-income economies that are expected to have rapid economic growth {10.3.3}.

Depending on if and how current policies and Nationally Determined Contributions are implemented, global temperatures could increase to 2.4 - 3.9°C this century, falling short of meeting the Paris Agreement temperature goal (*well established*). Global mean temperature rise is likely to exceed 1.5°C in the early 2030s, while with inadequate implementation of current policies, global mean temperature is projected to increase by about 3.9°C by 2100. Full implementation and continuation of current policies is expected to limit temperature increase this century to approximately 2.9°C (range: 1.8-3.5), while full implementation of unconditional Nationally Determined Contributions could reduce it to about 2.6°C (range: 1.8-3.4) and, for conditional Nationally Determined Contributions, to approximately 2.4°C (range: 1.8-3.3). All projections have at least a 50 per cent likelihood {10.4.1}.

Air and nutrient pollution of water are projected to remain high, with an increasing number of people exposed to levels above World Health Organization guidelines (*established but incomplete*). While globally most air pollution emissions are projected to decrease slightly between 2020 and 2050, the absolute number of people exposed to fine particulate matter concentrations ($PM_{2.5}$) above 25 µg/m^3 is projected to rise from 3.7 billion to 4.2 billion, mainly due to increasing urbanization and population growth in areas with high emissions. As a result, Sustainable Development Goal (SDG) 3.9 on mortality from environmental pollution and 11.6 on reducing environmental impacts of cities are unlikely to be achieved. Nutrient pollution, such as excess nitrogen and phosphorus, is also projected to increase, largely driven by growing levels from agriculture and human waste. The total area of groundwater, exceeding the World Health Organization standard levels of nitrogen concentration for drinking water (11.3 mg N/l), is projected to grow from 5.0 Mkm^2 in 2020 to 5.7 Mkm^2 by 2050 {10.4.2, 10.4.5}.

Land-use change and soil degradation are projected to continue through 2050, undermining progress towards land-degradation neutrality (*established but incomplete*). Around 100 million hectares of natural lands are projected to be lost between 2020 and 2050, mainly from cropland conversion. This is at the lower end of similar scenario projections in the literature. In addition, soil organic carbon in croplands is projected to decline by an average of 2.2 tC/ha, primarily due to intensive farming practices {10.4.3}.

Biodiversity is expected to decline across almost all dimensions, moving further away from the targets set in the Kunming-Montreal Global Biodiversity Framework (*well established*). Mean-species abundance, a measure of biodiversity intactness, is projected to drop from 59 per cent in 2020 to 56 per cent in 2050, compounding similar historic rates of loss since 1900. This loss in biodiversity is equivalent to the conversion of 4.6 million km^2 of pristine habitat, roughly comparable to the size of the European Union, to a habitat where all the original species are extinct. Land-use change remains the dominant driver, although the impacts of climate change on biodiversity are growing {10.4.4}.

The intensifying global environmental crises and associated pressures may trigger major shifts in the Earth system (*well established*). Tipping points, critical thresholds beyond which a system reorganizes, often abruptly and/or irreversibly, are a major concern. At least 25 Earth system tipping points have been identified, and 16 intersect the biosphere. Crossing Earth's tipping points could have catastrophic and hard to reverse impacts, affecting ecosystems and humanity. Examples of such tipping points include arctic sea ice loss that might alter the position and strength of the jet stream and the collapse of parts of the Antarctic and Greenland ice sheets that can cause significant and irreversible sea-level rise. In the tropics, the pressures of temperature rise, drought, deforestation and more intense and frequent wildfires may transform the

Amazon rainforest into a low tree-cover savanna. Similarly, Boreal and Temperate forests face potential dieback, while a 2°C rise in global mean temperature could nearly eliminate warm-water coral. Several tipping points are expected to be exceeded within this century, even with urgent global action. If the Equilibrium Climate Sensitivity is higher than generally assumed many climate-related impacts will be greater than currently estimated, and many climate-related tipping points will be breached much earlier than previously expected {10.5, Box 10.6}.

Not accounting for the full impacts of the global environmental crises, most dimensions of human well-being are projected to improve. However, progress remains unequal and insufficient to achieve socioeconomic SDG targets (*well established*). Basic material needs, such as access to food (SDG2), water (SDG6) and energy (SDG7), are projected to improve, and poverty (SDG1) to reduce. Also, health outcomes, including under-5 mortality (SDG5), are projected to improve over time. Nonetheless, the progress is insufficient to meet related SDG targets by 2030, and likely not even before 2050. {10.6.1, 10.6.2, 10.6.3, 10.6.4}.

Gains in human well-being are increasingly threatened by the intensifying global environmental crises, affecting human health, food systems and livelihoods (*well established*). By the 2050s, climate change could significantly increase the exposure of billions of people to extreme events, including heat waves, heavy rainfall, and droughts. Global environmental crises may reduce crop yields, undermining food security through changes in temperature and precipitation patterns, increasing pollution of air and soils, reduced soil quality, and decreasing pollination and pest control. Urban air pollution with fine particulate matter alone could be causing around 4 million premature deaths annually in 2050, a similar value to that in 2020. Global environmental crises could also increase injuries and the incidence of mental health problems in the general population and exacerbate health inequities for Indigenous Peoples. Additionally, the economic consequences of environmental degradation may slow poverty reduction and widen inequality between and within countries {Box 10.2, Box 10.6, 10.4.1, 10.4.2, 10.6.1, 10.6.2, 10.6.3}.

The economic costs of failing to address the global environmental crises are substantial and increasing over time (*established but incomplete*). While the economic costs and damages of climate change are relatively well investigated,, those associated with other environmental challenges remain fragmented and uncertain. Focusing solely on climate change, median estimates of the economic impacts are projected at about 4 (range: 0-7) per cent of the global gross domestic product in 2050, rising to approximately 20 (range: 3-37) per cent in 2100, including from reduced agricultural yields, damages to assets located in coastal or flood-prone areas, and a decline in labour productivity. As that assessment does not account for all four global environmental crises, broader societal impacts, or tipping points, the true economic burden of insufficient action on the global environmental crises could well be higher than this estimate suggest {10.6.5}.

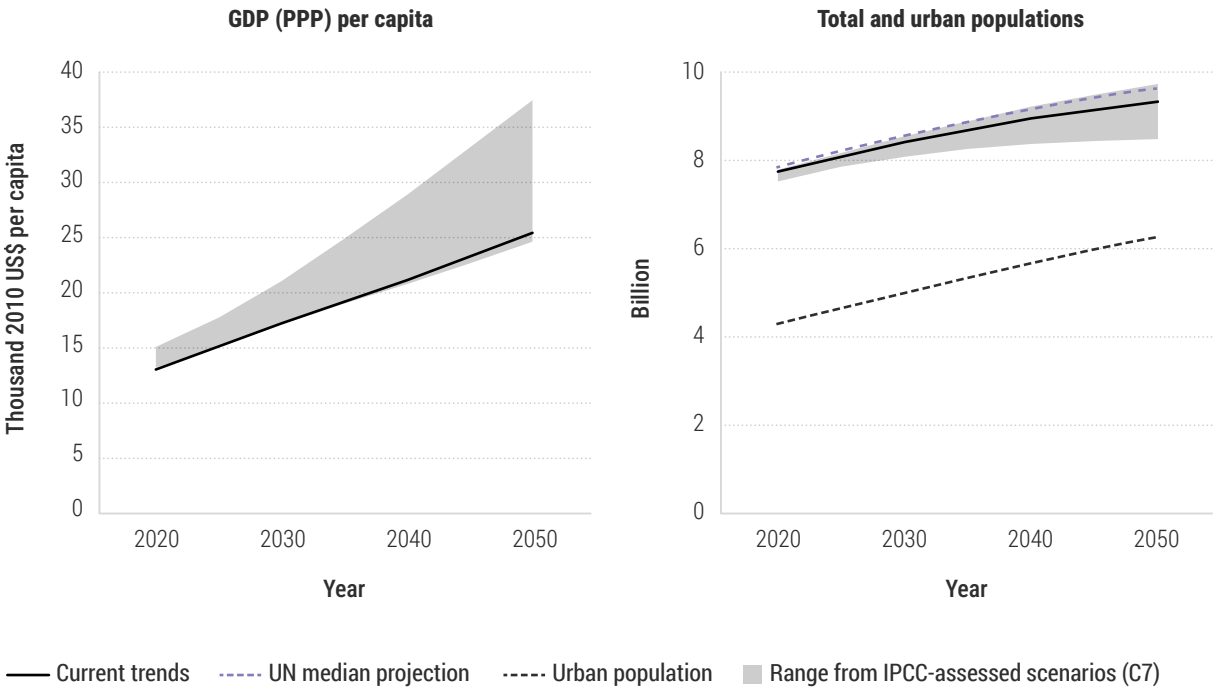
10.1 Introduction

The central question of this chapter is:

What are the likely environmental and socioeconomic outcomes if the current development trajectories continue?

To explore it, this chapter presents and discusses the GEO-7 Current Trends Scenario, developed specifically for this report (9.2). This scenario presents a future in which social, economic, and technological trends follow historical patterns. It is based on the Shared Socioeconomic Pathway 2 (SSP2) middle-of-the road scenario (O'Neill et al. 2017) and does not account for current policies and policy objectives. For climate change and air pollution, additional scenarios that incorporate these are presented, drawing on the existing literature.

By assessing the likely environmental and socioeconomic implications, the scenario is used to assess the extent to which internationally agreed environmental goals (9.3) are to be achieved without increased effort to address the global environmental crises of climate change, biodiversity loss and land degradation, and pollution and waste. In addition, the Current Trends scenario serves as a reference for the Transformation Pathway scenarios discussed in Chapter 11, highlighting the effort required to achieve the internationally agreed environmental goals. Note that this chapter focuses on the global level. Results for different income groupings and geographical regions are discussed in Chapters 19 and 20, respectively.



10.2 Drivers of environmental change under current trends

Chapter 2 provides an in-depth discussion of the drivers of environmental change, primarily focusing on historic trends. In this chapter, we present future projections of three core drivers within the Current Trends scenario: population and demographics, urbanization, and economic development (**Figure 10.1**). These drivers are the main inputs for the models used in the analysis presented in this chapter. Other drivers are incorporated in the overall broader narrative (O'Neill et al. 2017; Box 10.1).

Box 10.1: Narrative of the SSP2 Middle of the Road scenario

The world continues along a path where social, economic, and technological trends follow historical patterns with little deviation. Development and income growth remain uneven, with some countries advancing while others lagging behind. Most economies are politically stable. Globally connected markets function, albeit imperfectly. Technological development continues steadily, but without fundamental breakthroughs. Global population growth is moderate and stabilizes in the second half of the century, transitioning to low birth and death rates as the demographic transition proceeds. However, insufficient investment in education slows the transition to low fertility rates in low-income countries, keeping population growth higher than it could be. Gross Domestic Product (GDP) growth continues, but income inequality persists or improves only slowly, resulting in societal stratification and limited social cohesion. These factors hinder efforts to reduce vulnerability to societal and environmental changes and constrain significant advances in sustainable development.

Source: O'Neill et al. (2017)

It is important to note that the population and urbanization numbers used in the Current Trends scenario differ slightly from those presented in Chapter 2, which follows the United Nations medium projection (United Nations Department of Economic and Social Affairs 2024). Despite these variations, the basic narrative and overall future trends remain similar.

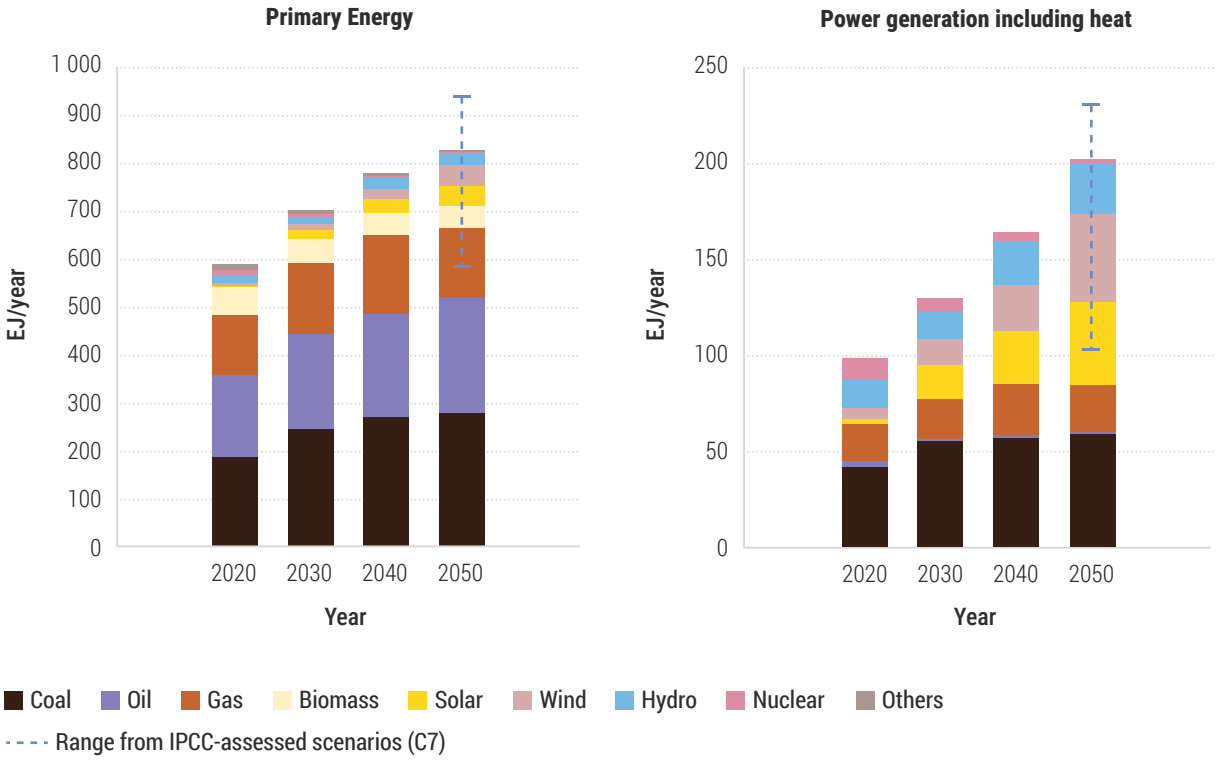
Although the global population growth rate is projected to decline, the population will continue to increase, from 8 billion people in 2020 to around 9.5 billion people in 2050, primarily driven by sustained high growth in Africa (KC and Lutz 2017). Also, urbanization trends are projected to continue, with most growth occurring in low- and middle-income countries. In 2025, around 55 per cent of the global population will live in urban areas, and that share is projected to rise to 67 per cent in 2050 (Jiang and O'Neill 2017). Finally, GDP per capita is projected to grow at around 2 per cent per year, nearly doubling global GDP, from 14,000 US$ (2010/capita) in 2020 to 28 0000 US$ (2010/capita) in 2050 (Dellink et al. 2017). Income inequality follows a generally flat trajectory (Rao et al. 2019).

10.3 Systems development under current trends

10.3.1 Energy

Although a range of international and national policy developments, such as the Paris Agreement and the responses to the 2022 energy crisis, have initiated a gradual shift toward carbon neutrality, the overall progress is insufficient to change the main drivers of greenhouse gas emissions significantly.

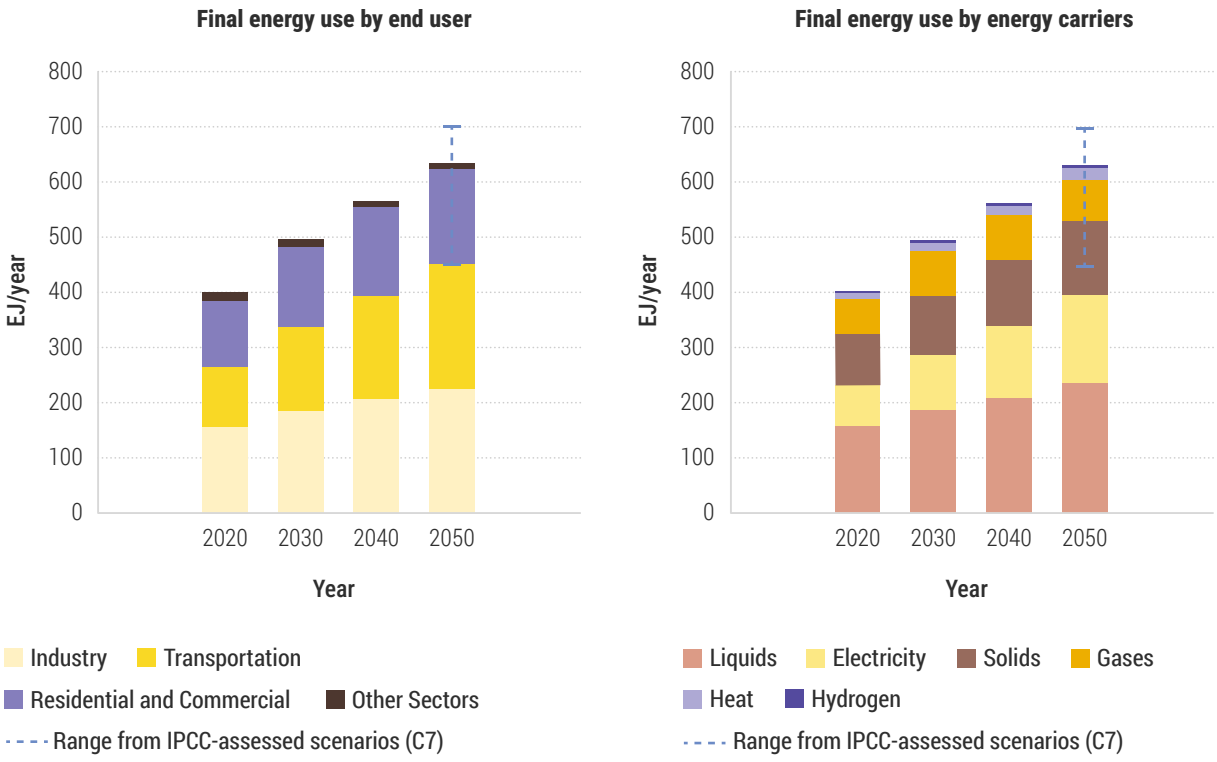
The Current Trends scenario projects a substantial increase in the renewable energy use in the total primary energy supply, driven by advances in technology like solar photovoltaics, wind power, electric vehicles and battery storage (**Figure 10.2**). However, fossil fuels will remain the dominant energy source by 2050. The most significant energy transition progress occurs in power generation, with low-carbon sources, including solar photovoltaics, wind, and nuclear energy, projected to hold a much larger share in 2030 and 2050, while coal use decreases slowly.



Energy demand is projected to increase sharply, but the growth rate varies by sector and over time (**Figure 10.3**). The transport sector shows the most significant growth due to a higher energy service demand and challenging electrification, while the residential and commercial sectors see a more gradual increase.

Technological progress and a shift from solid fuel use, including traditional biomass, to much cleaner and more efficient forms of energy, including electricity and gases, significantly improved energy efficiency in residential and commercial use. However, an increased energy demand driven by population and income growth offsets these efficiency gains.

The rapid increase in electricity in the energy mix is mainly driven by high economic growth in low-income countries where electrification remains limited. Falling costs of renewable electricity generation further enhance this trend (Intergovernmental Panel on Climate Change [IPCC] 2022a). Overall, the share of electricity in total final energy consumption is projected to increase from 15 per cent in 2020 to 25 per cent in 2050.



However, despite the growth in electrification, the overall energy mix remains largely dependent on fossil fuel-based energy carriers, such as coal, oil, and

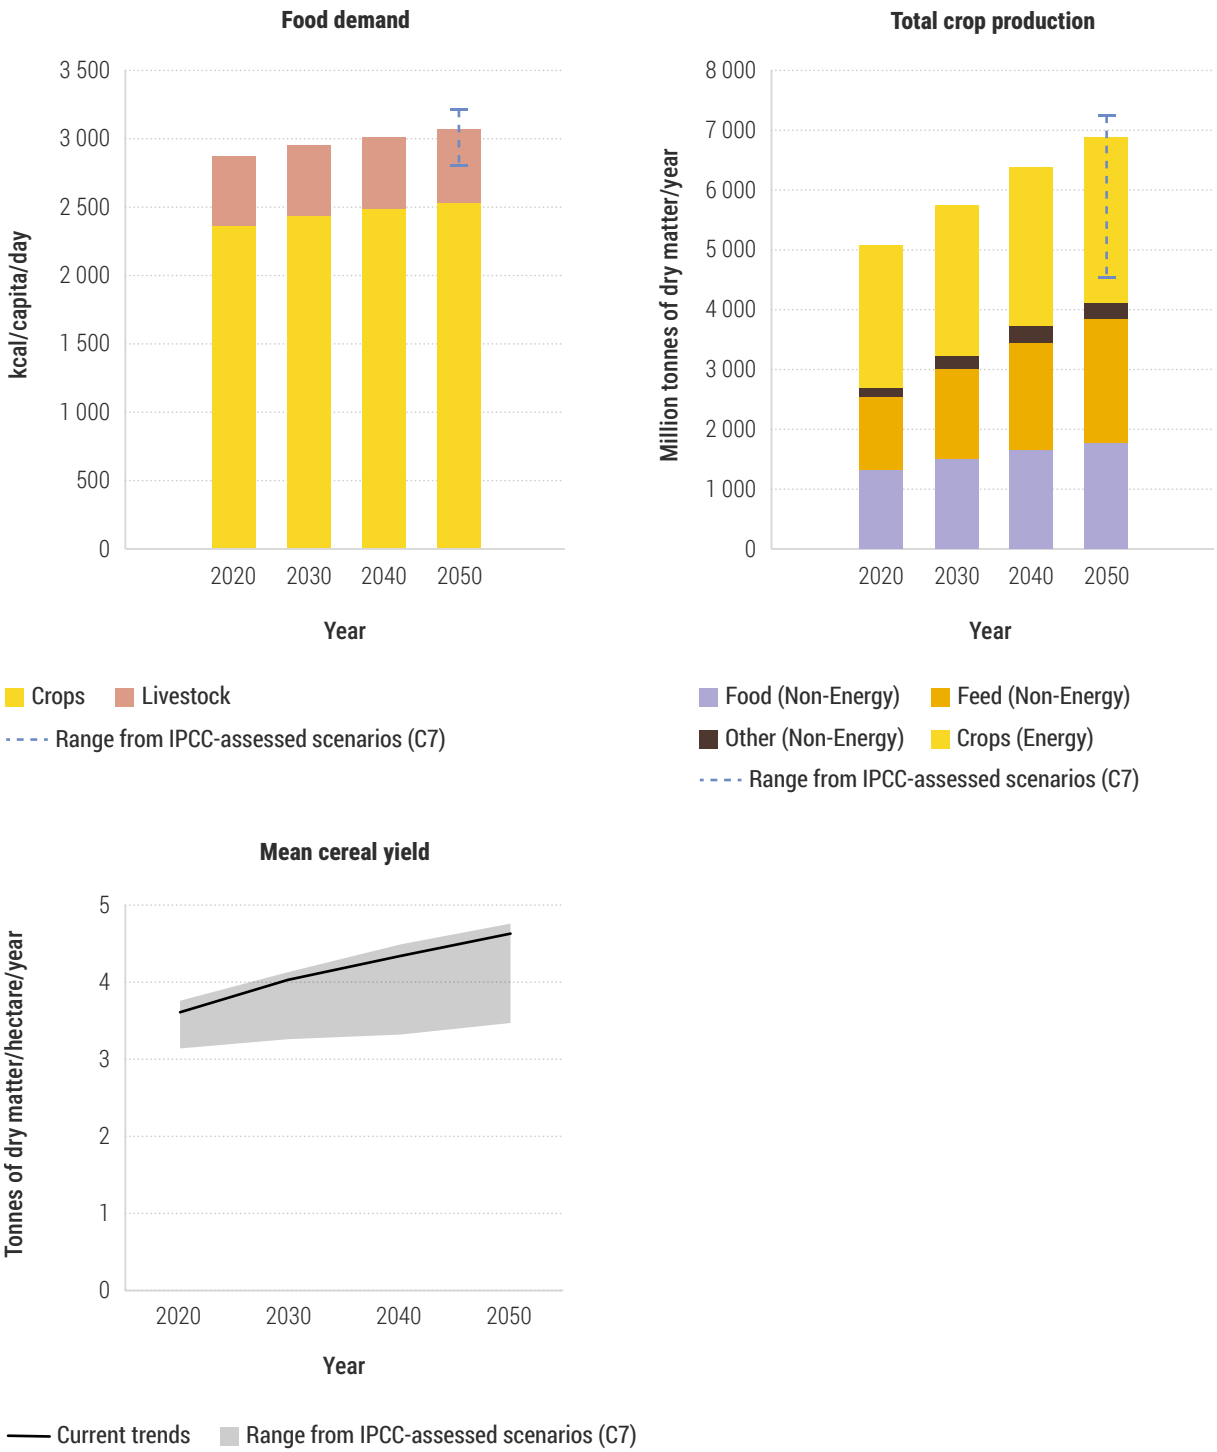
Figure 10.2: Primary energy use and power generation including heat

Source: AIM model and AR6 Scenario Database

Figure 10.3: Final energy use by end user and by technology

Source: AIM model and AR6 Scenario Database

natural gas, due to their relative affordability. As a result, this would imply that greenhouse gas (GHG) emissions remain high (10.4.1).



10.3.2 Food

Under the Current Trends scenario, the global food demand is projected to increase significantly by 2050 (**Figure 10.4**), driven both by an increase in per capita food demand and population growth. As incomes rise worldwide, the average daily food availability is projected to increase from almost 2900 kcal per capita per day in 2020 to a small 3100 kcal per capita per day in 2050. Low-income countries will see faster increases than the global average and the high-income countries, where food consumption rates are expected to remain relatively stable. For low-income populations, even modest income gains lead to sharp growth in food demand, while high-income groups show only slight increases (Muhammad et al. 2011). Moreover, low-income regions are more likely to shift from plant-based food to more animal-based food.

Global crop production is projected to increase by 40 per cent between 2020 and 2050 (**Figure 10.4**). During the same period, the total population is projected to increase by 20 per cent. This growth can be explained by the increase in per capita food consumption and the shift to animal-based diets, which raises the proportion of crops used as animal feed. While demand for biofuels is projected to increase slightly, it is not expected to significantly affect the production of major food crops or global crop production area. Alongside increased production and consumption, the food waste from production, processing, retail, and consumption is expected to rise (United Nations Environment Programme [UNEP] 2024a).

During the same period, the average global crop yield is projected to increase by 0.5 per cent per year (Figure 10.4), with higher gains in low-income regions (0.7 per cent/year) than in high-income regions (0.3 per cent/year), reflecting higher potential to improve agricultural technology and irrigation. The increase in yields is however much lower than the growth in agricultural production, indicating an expansion of agricultural land (10.4.3). However, due to model limitations, these projections only partially account for the effects of the global environmental crises on crop yields (**Box 10.2**).

Figure 10.4: Food demand, total crop production, and mean cereal yield

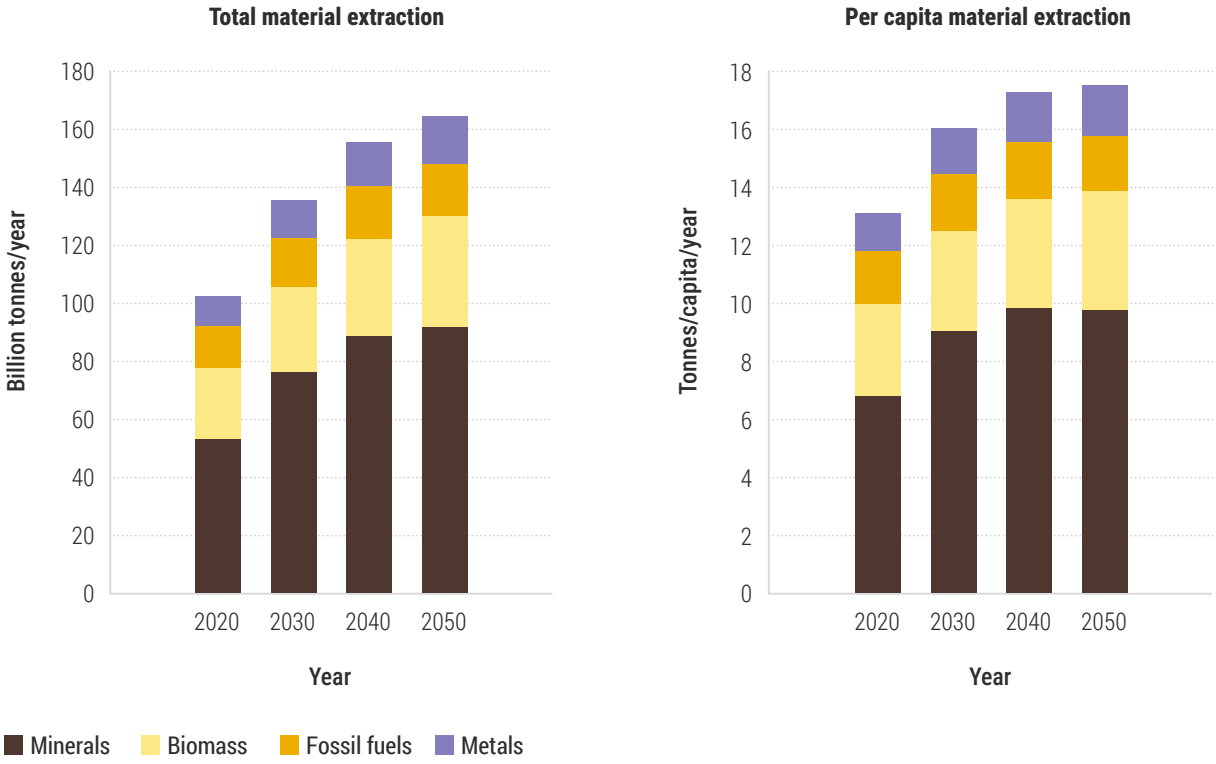
Source: AIM model and AR6 Scenario Database

10.3.3 Material resources

Over the past five decades, the global extraction of material resources – biomass, fossil fuels, metal ores and non-metallic minerals – has increased significantly, rising from 31.1 billion tons in 1970 to 96.5 billion tons in 2020 (UNEP 2024b). However, only 9 per cent of these materials were re-used in manufacturing and construction activities, resulting in significant economic loss and environmental impact.

Under the Current Trends scenario, the global extraction of material resources is projected to peak at 165 billion tons by 2050 (**Figure 10.5**), consistent with earlier

Box 10.2: Impacts of the global environmental crises on crop yields.



The impacts of changing temperature and precipitation patterns, along with higher levels of carbon dioxide (CO_2) fertilization on crop yields, are well documented, although high uncertainty remains. On average, temperate and boreal regions are projected to experience substantial increases in potential crop yields, while tropical regions may experience declines (Jägermeyr et al. 2021). Uncertainty mainly arises from potentially negative impacts of climate change, such as droughts and flooding, indicating the need for continued model development.

Different forms of pollution can affect crop yield. Air pollution leads to higher ozone levels, negatively affecting plant growth. Regions with high air pollution levels may see crop yield losses of up to 20 per cent (Chuwah et al. 2015). Soil pollution, including contamination with heavy metals or persistent organic compounds, directly harms crop yields (van der Esch et al. 2017). Additionally, inefficient irrigation systems or poor-quality water may lead to salinization or sodification, further diminishing productivity.

Land degradation processes significantly affect crop yields (van der Esch et al. 2022). For example, soil carbon loss due to ploughing and insufficient crop residue input leads to lower soil quality and water retention. Soil erosion from water or wind removes the fertile topsoil, while unsustainable soil management leads to crusting or compaction of soils.

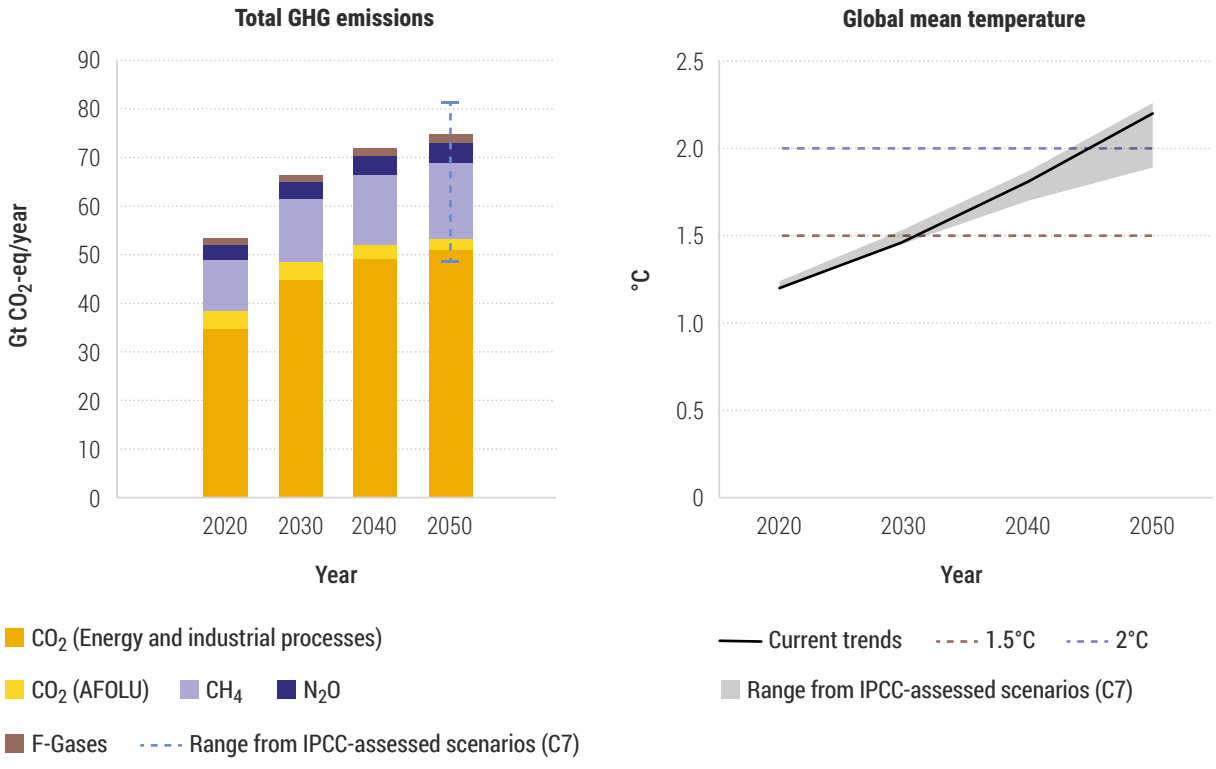
Ecosystem services, such as pollination and pest control that depends on biodiversity, enable agricultural production (Dainese et al. 2019). However, the impact of biodiversity loss on crop yields varies widely per crop type and remains uncertain (Albrecht et al. 2020). Integrating impacts of biodiversity changes in crop and food system projection models remains a major challenge (Seppelt et al. 2020).

Figure 10.5: Total and per capita global material extraction

Source: GTEM Model

studies (Organisation for Economic Co-operation and Development [OECD] 2019; UNEP 2024b). Asia and the Pacific will remain the largest consumers of global materials, peaking at 88 billion tons by 2050 and then gradually declining. The fastest growth is projected in Africa, with demand rising from 7.4 billion tons in 2020 to 19 billion tons in 2050. As a result, if current trends continue, global material per capita will increase from 13 tons per capita in 2020 and peak at 17 tons per capita by 2050.

The share of non-metallic minerals extraction is projected to grow from 52 per cent in 2020 to 56 per cent in 2050, mainly driven by the expansive growth of production in building, infrastructure and construction in low- and middle-income economies in Africa, and Asia and the Pacific that are expected to have rapid economic growth (Bleischwitz et al. 2018). Biomass extraction is also projected to increase, driven by rising food demand and dietary shifts to animal-based food in low-income countries, leading to a greater demand of fast grazed biomass and fodder crops (10.3.2). Due to the energy transition, the global fossil fuel use is projected to increase at a slower rate, compared to other categories of material resources (10.3.1).



10.4 Environmental implications under current trends

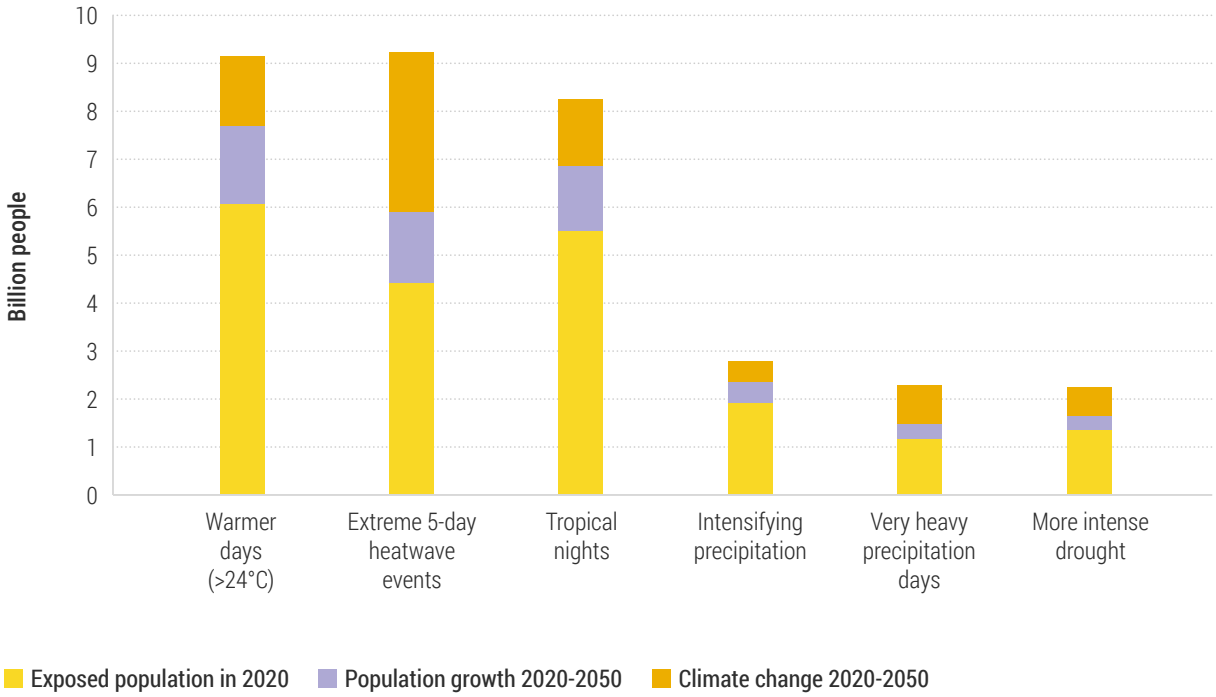
10.4.1 Climate change

The primary drivers of anthropogenic climate change are GHG emissions, including CO_2, methane (CH_4), nitrous oxide (N_2O) and fluorinated gases linked to the energy, food and materials/waste systems. Under the Current Trends scenario, GHG emissions are projected to increase and peak around mid-century (**Figure 10.6**), followed by a slight decline towards the end of the century. The energy sector remains the primary source of CO_2 emissions, due to continued use of fossil fuels (Clarke et al. 2022) (10.3.1). Land-use change is the second largest contributor, mainly driven by crop and pastureland expansion, linked to growing food demand (10.3.1, 10.4.3).

CH_4 and nitrous oxide emissions are projected to continue rising. The major drivers are increased food production through rice crops, livestock, and fertilizer use; waste generation; and other human activities. As a result of increasing GHG emissions, end-of-century warming could reach as high as 3.9°C, with a 50 per cent likelihood

Figure 10.6: Total GHG emissions and global mean temperature increase

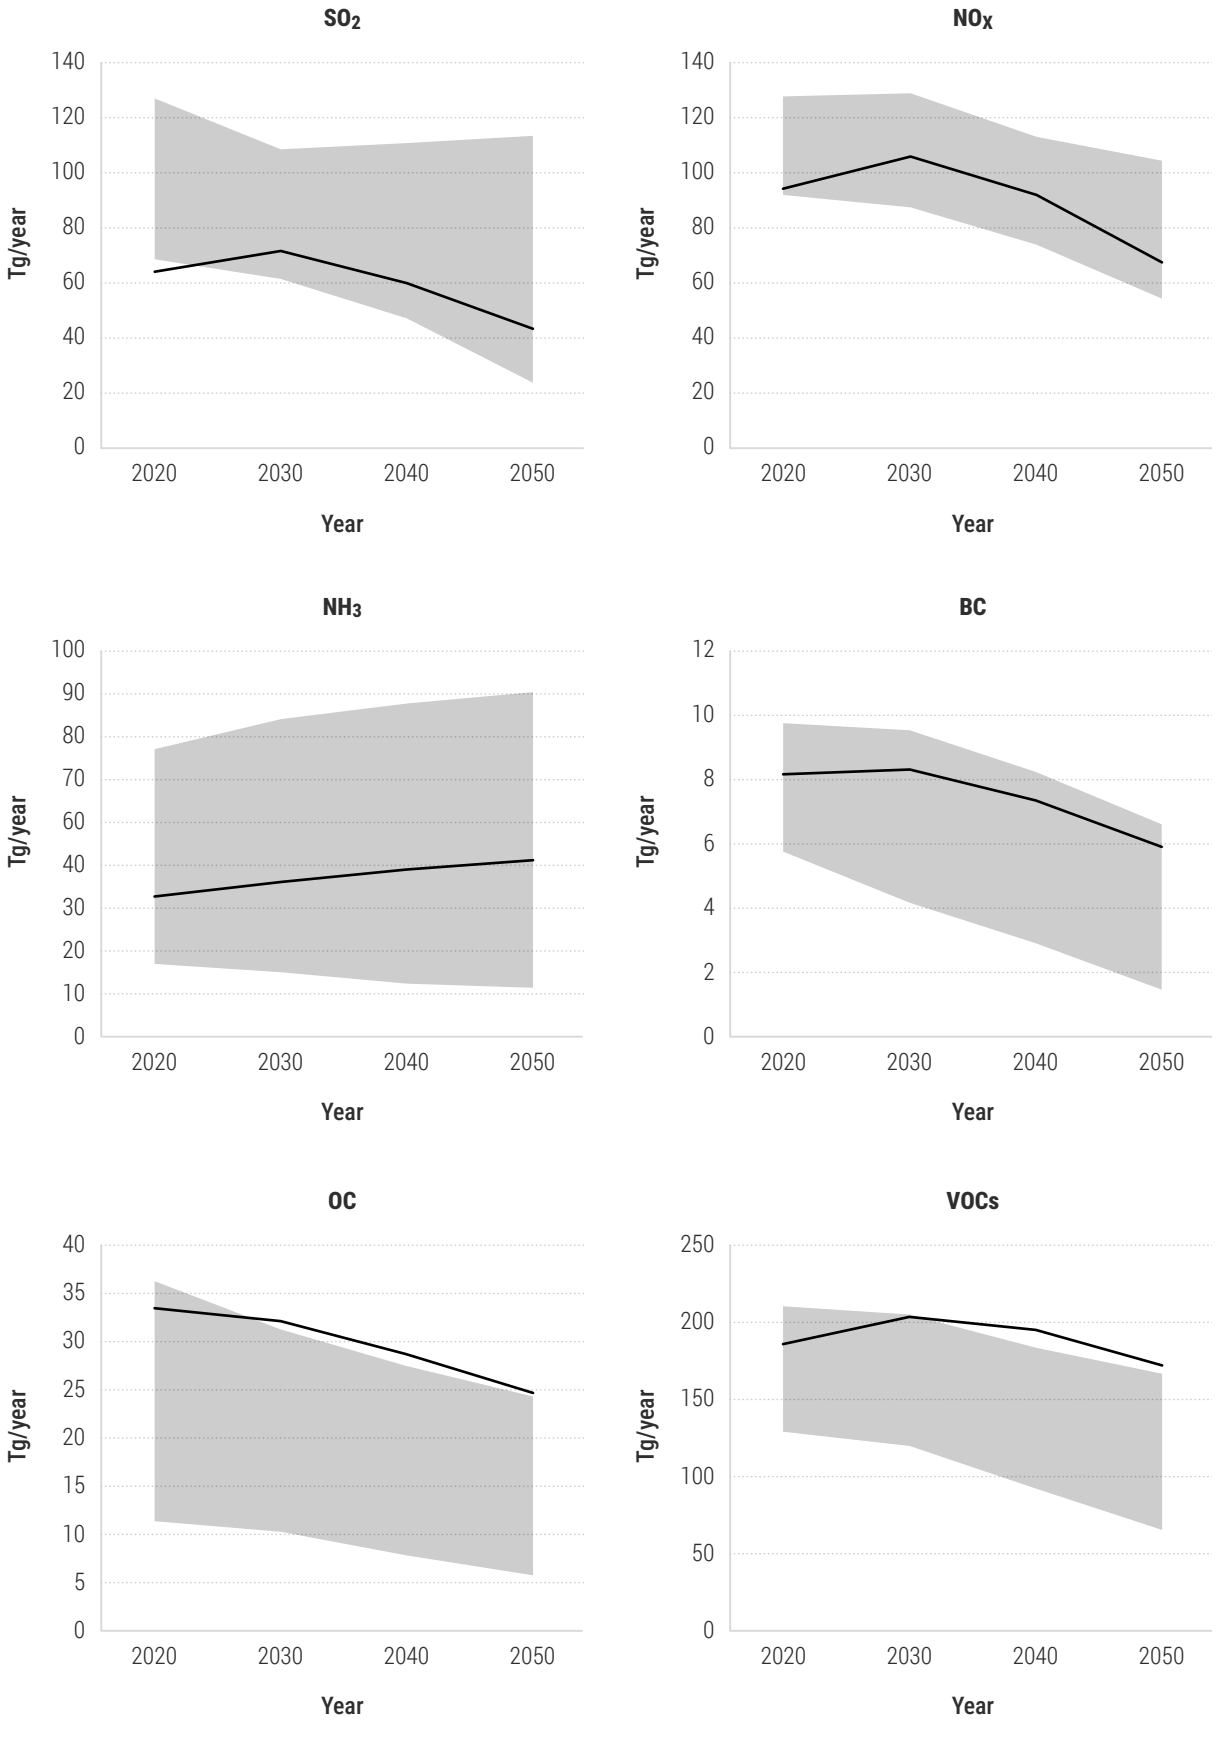
Source: AIM model and AR6 Scenario Database



(Figure 10.6). This projected warming of 3.9°C falls at the high end of the mitigation scenario category C7 presented in the sixth Assessment Report of the International Panel of Climate Change (IPCC), (IPCC 2022).

The Current Trends scenario does not explicitly include policies and policy objectives currently being implemented. UNEP (2024c) concludes that if current mitigation policies continue without integrating future Nationally Determined Contributions (NDCs), the global temperatures would increase this century to 2.9°C (range: 1.8-3.5) above preindustrial levels, with a 50 per cent likelihood. Including NDCs would only reduce the increase to 2.4°C (range 1.8-3.3) for conditional pledges and 2.6°C (range 1.8-3.4) for unconditional pledges. This underscores the importance of current climate policies, while highlighting their insufficiency in meeting the Paris Agreement goal of holding global average temperature increase to well below 2°C, with efforts to limit it to 1.5°C. During the early 2030s, the global mean temperature will likely exceed 1.5°C (IPCC 2023a).

Temperature increase will significantly affect climate system components, some of which will respond over decades, while others will take centuries (IPCC 2021). Under the Current Trends scenario, the global population exposed to the impacts of climate change is projected to increase significantly between 2020 and 2050 (**Figure 10.7**). While the population growth contributes, the primary driver of the increased exposure is climate change itself. Exposure for temperature-based impacts, such as heat stress and increased cooling needs (Tollefson 2025), will be much higher than for hydrological impacts. The number of people exposed to consecutive tropical nights, with minimum air temperatures above 20 °C, will rise, potentially affecting sleep patterns and health. Meanwhile, increased exposure to heavy precipitation poses risks for agriculture and increased flooding, while increased droughts could lead to critical water scarcity (10.4.6).



Climate change adaptation strategies, such as heat action plans, enhanced water management, strengthening agricultural resilience, and safeguarding vulnerable ecosystems, will play a crucial, yet limited role in reducing the impacts of these temperature increases. Soft and hard adaptation limits are already being reached in both human and natural systems, these challenges will intensify with further warming. Achieving climate-resilient development becomes increasingly complex, especially if 1.5°C warming is exceeded in the near term (IPCC 2022a).

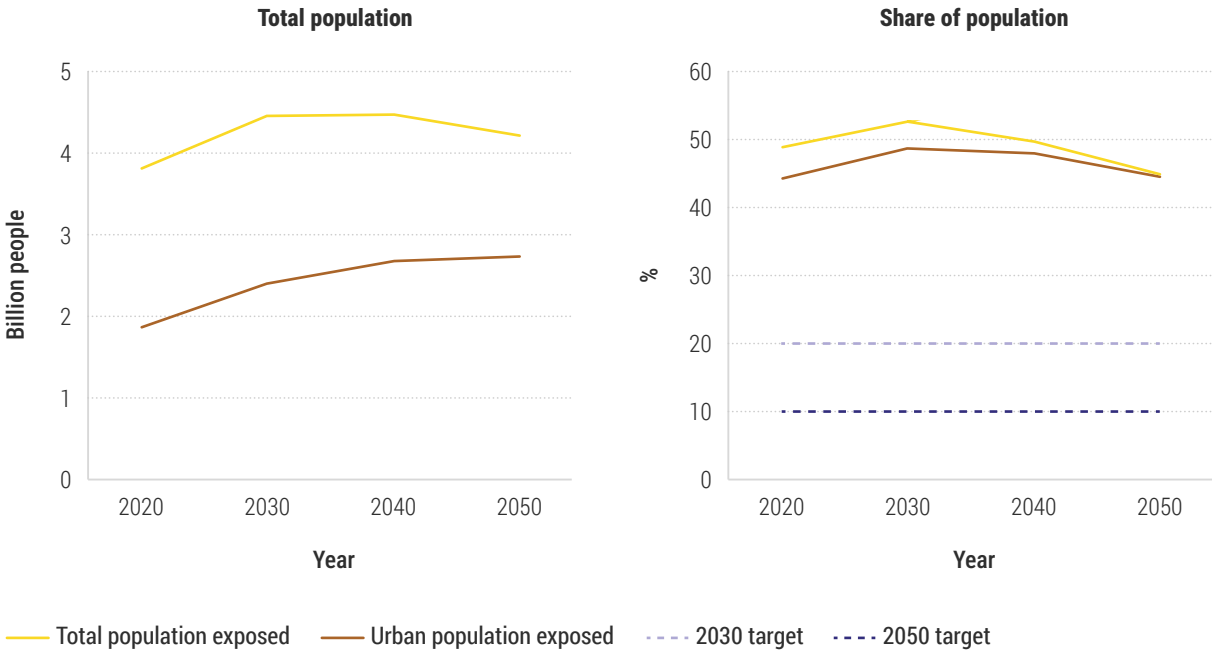
10.4.2 Air pollution



Fine particulate matter ($PM_{2.5}$) and ozone are the most harmful air pollutants for human health and ecosystems (Health Effects Institute 2024; 3.1). Both are mostly secondary pollutants formed in the atmosphere due to physical and chemical processes (Vallero 2014). $PM_{2.5}$ precursors include sulphur dioxide (SO_2), nitrogen oxides (NO_x), ammonia (NH_3), black carbon (CB), and organic carbon (OC). Ozone formation includes NO_x, non-methane volatile organic compounds (VOCs), carbon monoxide (CO), and CH_4.

Under the Current Trends scenario, most air pollution emissions are projected to decline between 2030 and 2050 (**Figure 10.8**). The reduction in sulphur dioxide emissions is mainly associated with reduced use of solid fuels in power plants and industrial facilities. At the same time, the drop in NO_X derives from abatement in the transportation sector and reduced combustion in power generation and other industries. The drop in OC and primary $PM_{2.5}$ emissions, including black carbon, would mainly result from emissions reductions in the building sector, while non-methane volatile organic compounds would primarily be reduced by industrial and residential combustion improvements. CH_4 and NH_3 emissions are projected to increase throughout the observed period. This upward trend is mainly linked to the limited mitigation in agricultural production, particularly in livestock management and fertilizer application.

Driven by these emissions trends, global $PM_{2.5}$ and ozone concentration are projected to decrease slightly by 2050. $PM_{2.5}$ global annual average population-weighted concentration is projected to drop from 28 µg/m^3 in 2020 to 27 µg/m^3 in 2050. Ozone annual average global population-weighted concentration is projected to decrease from 42 ppb in 2020 to 41 ppb in 2050. These pollution levels vary by region. $PM_{2.5}$ concentrations are thehighest in Africa, Asia and the Pacific, while ozone concentrations are most pronounced in Asia and the Pacific.

Despite the slight decrease in $PM_{2.5}$ levels, the number of people exposed to concentrations above 25 µg/m^3 is projected to increase, from 3.7 billion in 2020 to 4.2 billion in 2050 (Figure 10.9), due to population growth, particularly in urban areas in low-income countries. So, while the proportion of the global population exposed to $PM_{2.5}$ levels above 25 µg/m^3 is projected to decrease slightly from 50 per cent in 2020 to 45 per cent in 2050, the urban share of this exposed population remains relatively stable at 45 per cent (**Figure 10.9**). This trend indicates that Sustainable Development Goal (SDG) targets 3.9 and 11.6, which aim to reduce death and illness from air pollution and improve urban air quality, are unlikely to not be met.

Figure 10.9: Total population and share of population exposed to $PM_{2.5}$ levels above 25 µg/m^3

Source: JRC-FASST model

The Current Trends scenario shows only limited improvement in air quality, primarily because it does not account for the announced air pollution abatement measures and the Paris Agreement NDCs. According to the International Institute for Applied Systems Analysis (2019), including these measures could further reduce the global average exposure by 2050: $PM_{2.5}$ by 19 per cent and ozone by 13 per cent. However, these lower levels still fall short of meeting the SDG targets. The projected decrease in air pollution levels mainly stems from significant additional abatement in sulphur dioxide (50 per cent) and NO_X (30 per cent) emissions, driven by a reduction in fossil fuel use in the energy, industrial and transport sectors. Other contributing factors are modest reductions in black carbon and primary $PM_{2.5}$ emissions from the building sector, while there are little to no reductions in NH_3 and CH_4 emissions due to the lack of robust policies targeting the agriculture sector.

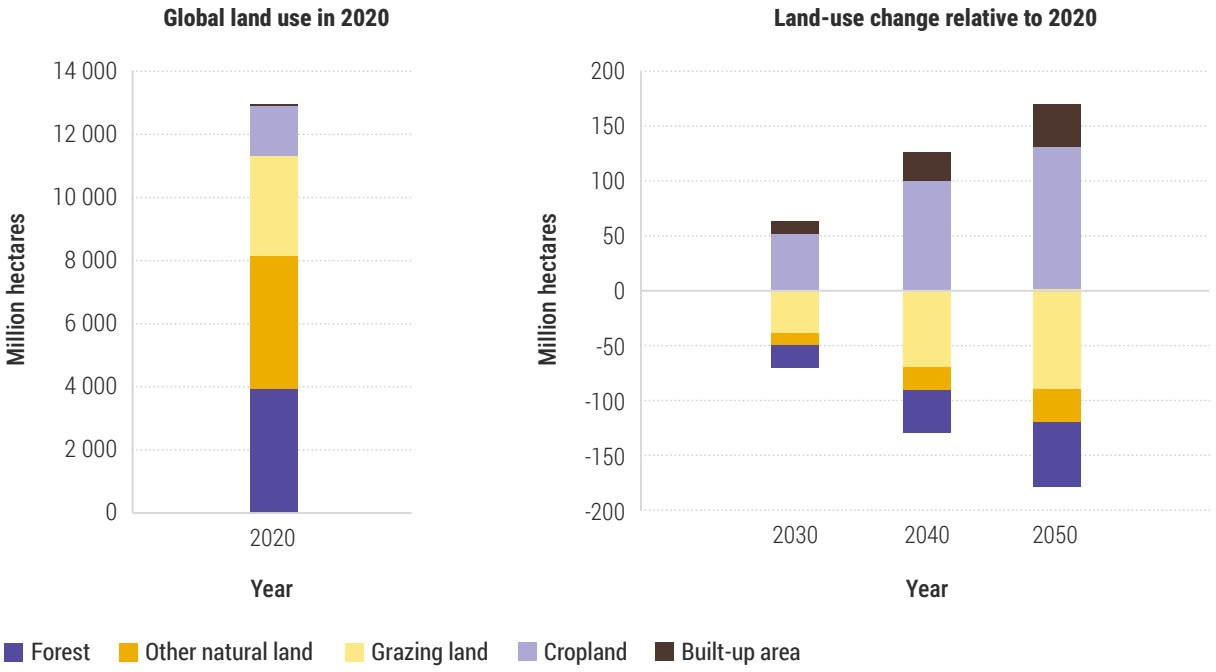
10.4.3 Land degradation

The United Nations Convention to Combat Desertification defines land degradation neutrality as maintaining land's capacity to provide ecosystem services, such as food production, carbon storage and biodiversity, measured by trends in land cover, carbon stocks and land productivity (Orr et al. 2017). The Current Trends scenario projects continued conversion of natural land and soil carbon losses in agricultural lands, implying that land degradation neutrality will not be achieved (**Box 10.3**).

Agricultural land is projected to increase slightly towards 2050, as yield improvements fail to meet the growing food demand (10.3.2). Although to a much lesser extent, increased bioenergy demand, particularly in the transport sector, also contributes to this growth. As a result, total cropland is projected to expand by almost 150 Mha between 2020 and 2050 (**Figure 10.10**). During the same period, both pastureland and natural land are projected to decrease by almost 100 Mha each. This projected decrease in natural land is at the lower end of similar scenario projections (Popp et al. 2017; PBL 2022).

Land-use change and shifts in climate dynamics lead to significant changes in carbon stocks, both above and below ground. Aboveground carbon losses are most pronounced in Sub-Saharan Africa and Latin America, where deforestation and conversion of other natural land, as well as forest degradation related to wood harvesting, reduce carbon storage. Conversely, in the boreal regions, a substantial increase in carbon stocks is projected due to climate change leading to the expansion of forests. Existing forests may also show modest increases in carbon stocks due to CO_2 fertilization. The positive and negative effects

Box 10.3: Land restoration pledges under different conventions.



As of 2020, at least 115 countries have committed to restoring 1 billion hectares of land (Sewell, van der Esch and Löwenhardt 2020). These commitments include:

- 450 million hectares through the land degradation neutrality national voluntary target-setting programme,
- 250 million hectares committed through the NDCs under the Paris Agreement
- 90 million hectares pledged in the National Biodiversity Strategies and Action Plans (NBSAPs) under the Convention on Biological Diversity (CBD).
- 210 million hectares under the Bonn Challenge and associated regional initiatives

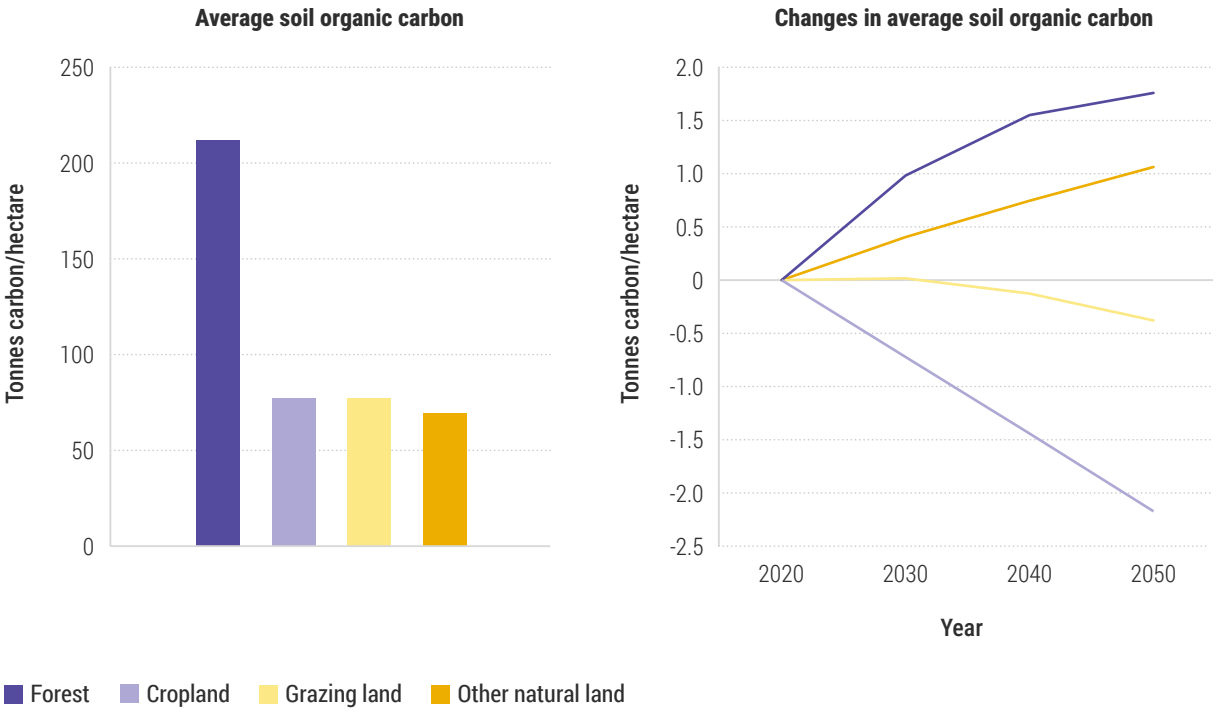
Nearly half of these restoration commitments are concentrated in sub-Saharan Africa. South Asia, China, and Central and South America also have significant commitments relative to their land area.

The commitments are relatively equally divided between ecological restoration and protection, and improved land management and the rehabilitation of degraded land. Overall, the current commitments cover roughly one-fifth of global cropland, one-tenth of all forest area, and a small share of pastures.

Figure 10.10: Global land use and land-use changes relative to 2020

Source: AIM Model

counterbalance on the global scale, leading to a modest net reduction in total vegetation carbon stocks of 14 GtC between 2020 and 2050.



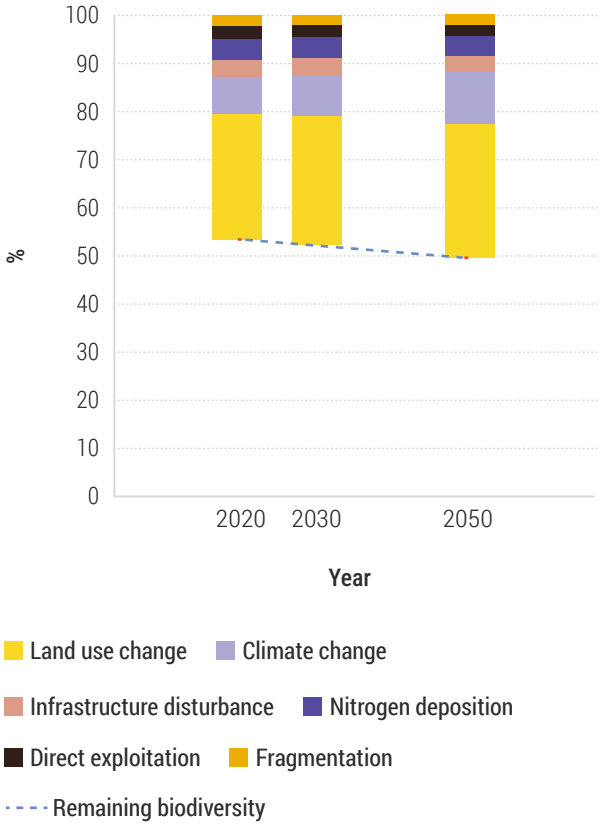
Changes in soil organic carbon (OC) are projected to show mixed patterns, with decreases in soil OC in agricultural lands and increases in natural lands (**Figure 10.11**). In cropland, soil OC continues to decline, with intensive management practices leading to an average loss of 2.2 tC/ha from 2020 to 2050. Additionally, the expansion of agriculture into natural lands reduces soil OC. In natural lands, higher temperatures accelerate decomposition rates, reducing stocks. However, faster vegetation growth rates increase litter input, increasing carbon stocks. Overall, the Current Trends scenario projects a slight increase of 5 GtC in soil OC between 2020 and 2050. It should be noted that these model-based estimates carry considerable uncertainty, and estimates from other studies vary widely (Krause et al. 2017).

10.4.4 Biodiversity loss

Biodiversity loss is driven by a range of factors, including land-use change, climate change, pollution, natural resource use and exploitation, and invasive species (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services 2019; Jaureguiberry et al. 2022). Under the Current Trends scenario, Mean Species Abundance (MSA) (Schipper et al. 2020), a measure of biodiversity intactness, is projected to decrease by 3.5 per cent points, from 59 per cent in 2020 to 56 per cent in 2050 (**Figure 10.12**), compounding similar historic rates of loss since 1900 (Pereira et al. 2024). This decline is equivalent to converting 4.6 million km^2 of pristine habitat, roughly the size of the European Union, to a habitat where all the original species are locally extinct. While the relationship between MSA and species extinction is not linear, the decline in 3.5 per cent points could result in the extinction of approximately 16,000 to 160,000 species (Pereira et al. 2024). As a result, global biodiversity targets, including the halt of biodiversity loss by 2030, are unlikely to be met. **Box 10.4** describes implications of biodiversity loss on Indigenous Knowledge.

Land-use change (10.4.3) remains the most significant driver of biodiversity loss, accounting for 23 per cent of MSA loss in 2020, and increasing to 25 per cent in 2050. The impact of climate change is projected to become increasingly significant, contributing 7 per cent of MSA loss in 2020, and rising to 10 per cent in 2050, driven mainly by global temperature increase (10.4.1). The impacts of nitrogen deposition (10.4.5) remains relatively stable towards 2050, contributing around 4 per cent of MSA loss. Other factors of biodiversity loss, not explicitly accounted for in this projection, include the increase of invasive exotic species and

Figure 10.11: Average soil organic carbon in 2020 and changes in average soil organic carbon



Source: IMAGE-LPJmL Model

ongoing pollution by many different substances, such as pesticides, plastics, medicines and many others (Balvanera et al. 2019) (4.3; 6.5).

The projected trend aligns with earlier studies on MSA projections (Secretariat of the Convention on Biological Diversity [CBD] 2020; Van der Esch et al. 2022; Kok et al. 2023) and is consistent with the broader literature. Model projections indicate negative trends across almost all dimensions of biodiversity, from local population declines and reduced diversity to global species extinction rates (Pereira et al. 2024). The extent of suitable habitats for terrestrial vertebrates, including mammals, birds, amphibians and reptiles, may decrease by about 50 per cent between 2010 and 2100. Estimated global extinctions – species committed to extinction – could range between 2 per cent and 8 per cent by 2100.

Figure 10.12: Loss of Mean Species Abundance (MSA)

Source: GLOBIO Model

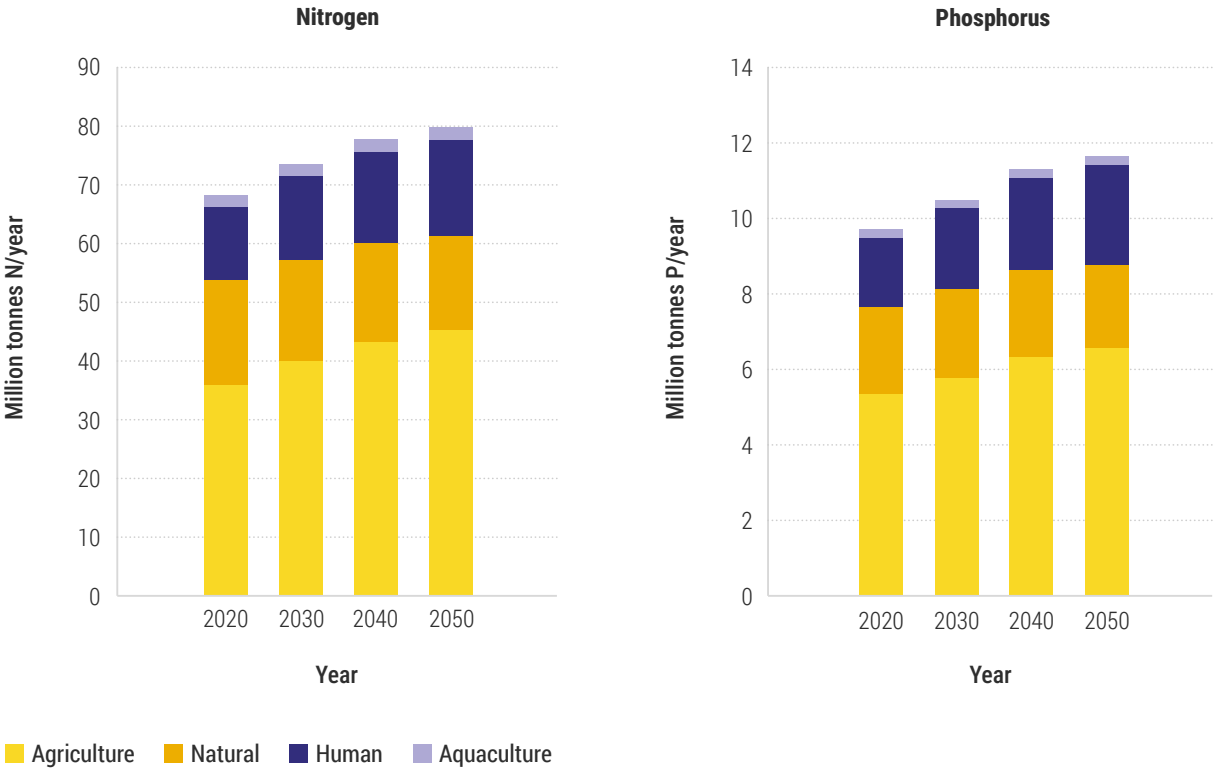
10.4.5 Nutrients pollution

Excess nitrogen (N) and phosphorus (P) are causing eutrophication in freshwater, estuaries and coastal waters (Seitzinger et al. 2010; Bouwman et al. 2024). Eutrophication occurs when nutrient accumulation stimulates overgrowth of organisms that may deplete the oxygen in the water, harming aquatic life. Excess nutrients from agriculture, aquaculture,

Box 10.4: Implications of biodiversity loss on Indigenous Knowledge

Evidence highlights the crucial role of Indigenous Peoples and Indigenous Knowledge and philosophies for biodiversity preservation and enhancement (World Health Organization and the Secretariat of the CBD 2015; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services 2019). Indigenous methods of biodiversity management are deeply rooted in local contexts, emphasizing reciprocity, responsibility, and care toward the soil, animals, plants, and other entities on their lands (Ogar, Pecl, and Mustonen 2020; Reyes et al. 2024). Indigenous Knowledge systems are built on empirical observations of local weather patterns, seasonal cycles, and the behaviours of flora and fauna, passed down through generations (Savo et al. 2016; Nkuba et al. 2020; Fernández-Llamazares et al. 2021).

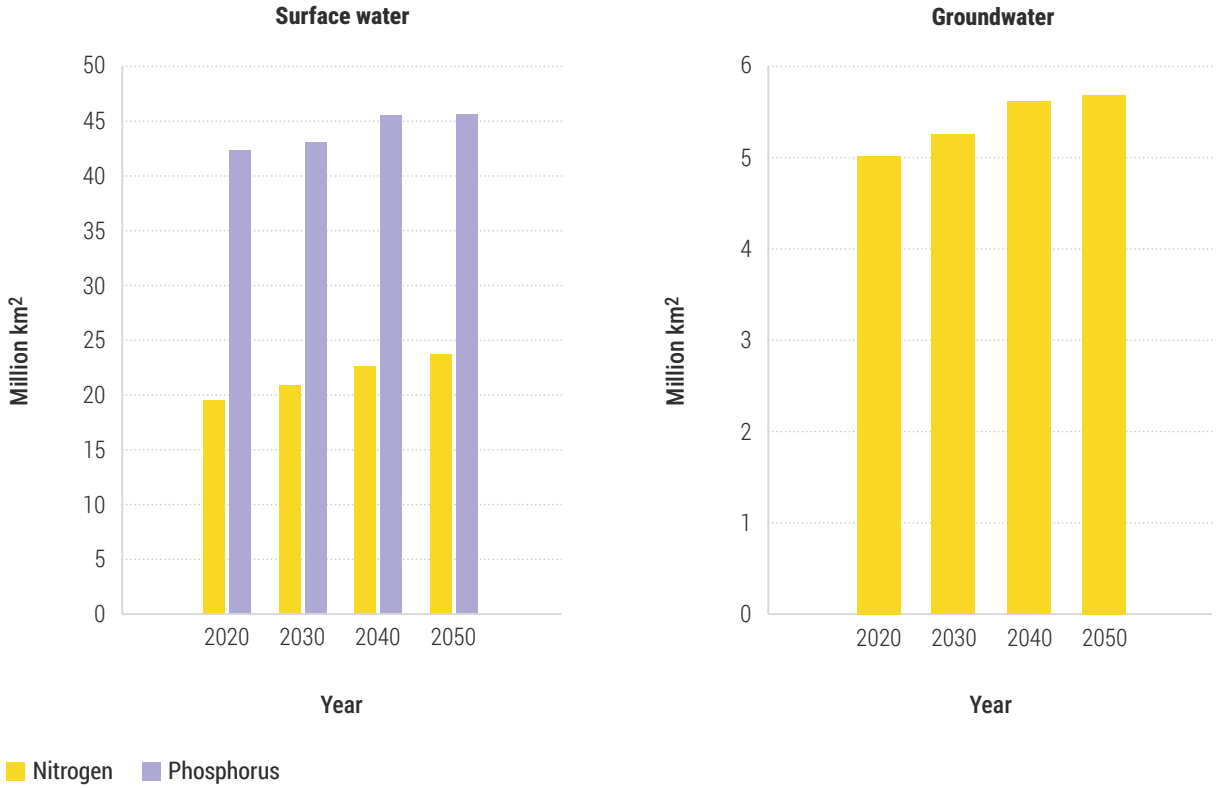
The most biodiverse areas in the world are often inhabited by Indigenous Peoples (Fa et al. 2020, O'Bryan 2021). Biodiversity is integral to various Indigenous cultural, food, medicinal and economic systems (IK & LK Dialogues 2025). In Canada, Indigenous Peoples maintain reciprocal relationships with the entire landscape, encompassing water, air, flora, and wildlife (Galway, Esquega, and Jones-Casey 2022). In the Amazon, Indigenous Peoples sustainably use, conserve, and regenerate forest and farm resources (Arotoma-Rojas et al. 2022; Pesantes et al. 2024). Traditional medicinal knowledge, which is valuable for both Indigenous and public health, plays a significant role, with 40 per cent of pharmaceutical products derived from traditional knowledge (World Health Organization 2023; Chaachouay and Zidane 2024).



Current trends in environmental change threaten the transmission of Indigenous Knowledge. This, in turn undermines the sustainable management of wild and domesticated biodiversity and jeopardizes traditional and allopathic medicines, posing a risk to human health (Mistry, Bilbao and Berardi 2016; Hoffman et al. 2021). Urbanization, pollution, and climate change are key drivers of biodiversity loss in lands inhabited by Indigenous Peoples (Savo et al. 2016; Brubacher et al. 2024). Furthermore, the historical and ongoing impacts of colonization and social exclusion compound with environmental changes, leading to forced displacement and the loss of ancestral lands and languages (Fa et al. 2020; Zavaleta-Cortijo et al. 2020; Redvers et al. 2023). These challenges not only affect the well-being and health of Indigenous Peoples (IK & LK Dialogues 2025), but also have negative repercussions for broader societal efforts to adapt to climate change and foster biodiversity resilience in the future.

and human and industrial waste are key contributors to groundwater and surface water pollution. While industrial wastewater was the leading cause of nutrient pollution in the early 20th century, agriculture has now become the predominant contributor.

In the Current Trends scenario total delivery of N and P to surface water is projected to increase by 2050, primarily driven by agricultural activities and human waste (**Figure 10.13**). The results for N are in line with the International Nitrogen Assessment (forthcoming). Nutrients pollution from agriculture stem from fertilizer use, manure application to cropland and grassland, expansion of soybean cultivation, and nitrogen deposition due to increasing NH_3 and NO_x emissions from livestock production, and NO_x emissions from fossil fuel combustion. The rise of nutrient pollution from human waste is driven by population growth and increased sanitation levels, resulting in higher waste loads, while increased wastewater treatment partly offsets this increase.



As a result of increasing nutrient delivery, water quality is projected to decline, albeit with substantial geographic differences. The total area of groundwater and surface water that exceeds water quality thresholds is projected to grow (**Figure 10.14**). While each country and water body has their thresholds and standards, here, we use the global water quality standards proposed by Bouwman et al. (2024). For N, in 2020, almost 19.5 Mkm^2 exceeded the environmental threshold of 2.5 mg N/l in surface water. This area is projected to increase to 23.7 Million Km^2 by 2050, accounting for 18 per cent of the total land area globally. For P, the area exceeding the ecosystem threshold of 0.1 mg P/l in surface water is projected to increase from 42 Mkm^2 in 2020 to 46 Mkm^2 by 2050. Finally, for groundwater, the area exceeding the World Health Organization drinking water standard threshold of 11.3 mg N/l is estimated to rise from 5.0 Mkm^2 in 2020 to 5.7 Mkm^2 by 2050.

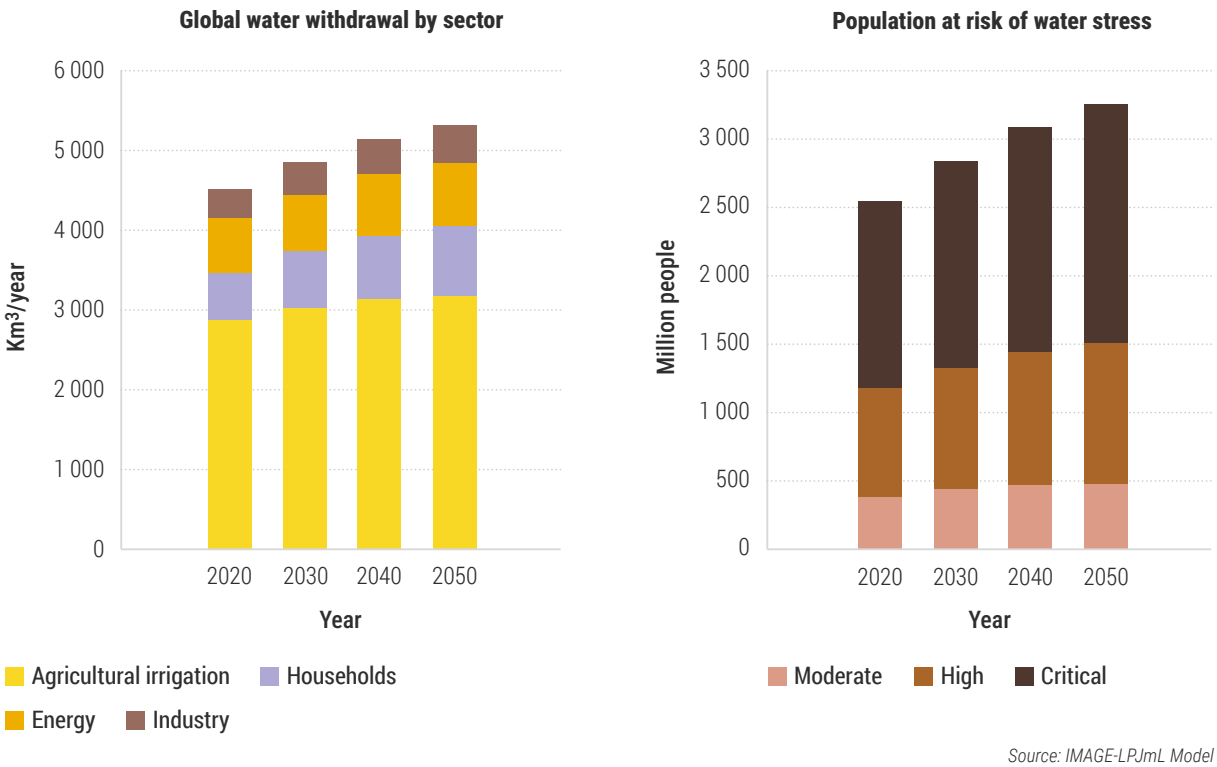
10.4.6 Water scarcity

Increasing water withdrawal, combined with the impacts of climate change on water availability, will intensify pressure on water resources, potentially leading to water scarcity in certain regions. Water scarcity can affect various sectors, including energy generation, domestic use and agriculture. Reduced water availability can decrease hydropower generation and limit cooling capacity in conventional energy plants. Furthermore, restrictions on domestic water use may be necessary, while water scarcity in agriculture can lead to decreased crop yields.



Under the Current Trends scenario, global annual water withdrawal is projected to rise by around 18 per cent (800 km^3) between the 2020 and 2050, with an increase of 11 per cent (310 km^3) for irrigation water, despite improvements in irrigation efficiency, and 30 per cent (490 km^3) for households, industry and energy (**Figure 10.15**). Key drivers are population growth, economic development, cropland expansion, and a growing demand for industrial and cooling water (Wada et al. 2016). A significant increase in total water use is expected from both municipal and industrial sources (Bijl et al. 2016).

Due to changes in precipitation and snowmelt patterns, combined with limited surface water availability, withdrawals from groundwater are projected to increase further. Groundwater is generally not a renewable source, further affecting future water scarcity. Significant withdrawals are expected in South Asia, Northeastern China, the western United States, Mexico, and the Nile region.

A location is considered at risk of water stress if more than 10 per cent of its water withdrawals come from non-renewable sources, such as deep aquifers or desalination, due to the lack of surface water or renewable groundwater. Between 2020 and 2050, the overall area at risk of water stress is projected to increase by 1 per cent, while the number of people living in water-stressed areas is projected to increase by 28 per cent, equivalent to 710 million people (**Figure 10.15**). As, during the same period, the global population is projected to increase by 17 per cent, this trend reflects high population growth in already water-stressed areas.

Agriculture is the major water consumer. In irrigated farming, surface water scarcity will drive the use of non-renewable groundwater, as long as it remains

Figure 10.15: Global water withdrawal and population at risk of water stress

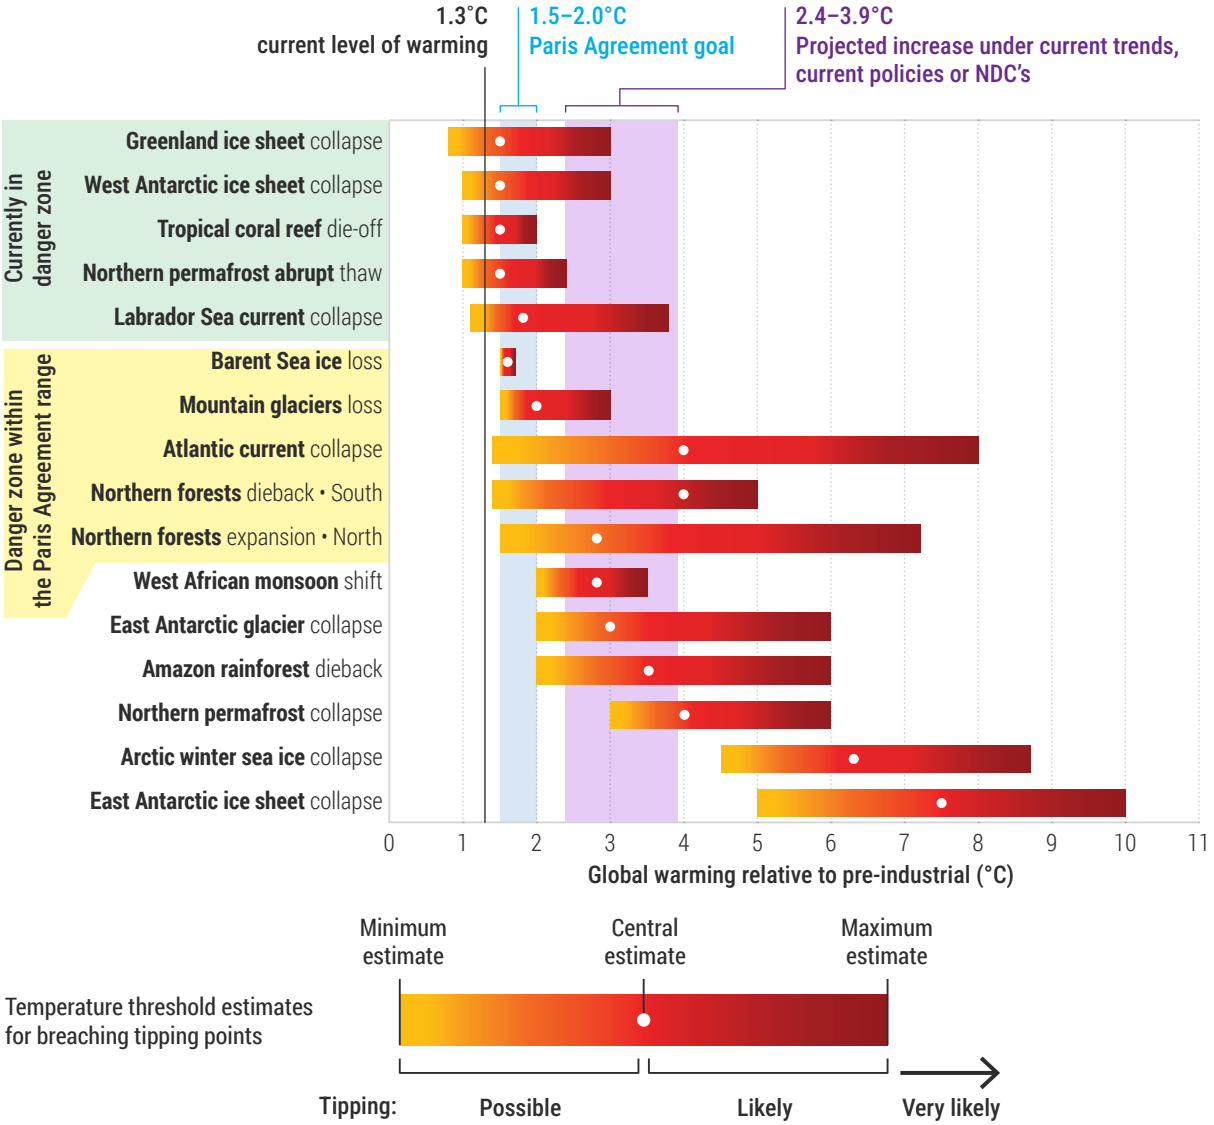
Source: IMAGE-LPJmL Model

Credit: JuiceFlair/Envato

accessible. However, when groundwater levels drop too low, absolute water shortages become inevitable (de Graaf et al. 2019), resulting in a decline in crop production. For rainfed crops, reduced precipitation or "green water scarcity" immediately affects crop yields or can even lead to crop failure. Since rainfed agriculture accounts for approximately 80 per cent of cropland and 60 per cent of total crop production, green water management is crucial for ensuring food security (Liu et al. 2022).

10.5 Tipping points and non-linearities

The global environmental crises pose a significant risk of triggering major shifts in the Earth's system. Tipping points, critical thresholds beyond which a system reorganizes, often abruptly and/or irreversibly (Solé and Levin 2022), are of particular concern (Lenton 2013).



Researchers have identified more than 25 Earth system tipping points, 16 of which intersect the biosphere (Lenton et al. 2019; Lenton et al. 2023). Crossing these tipping points could have catastrophic and potentially irreversible impacts on people and biodiversity (Lenton et al. 2023). Under the Current Trends scenario, several system tipping points are expected to be breached within this century, and even if the Paris Agreement goal of holding global average temperature increase to well below 2°C is met, some may be unavoidable (**Figure 10.16**).

The global environmental crises exhibit non-linear dynamics, characterized by accelerated rates of change and distinct tipping points. As tipping points are not part of the modelling framework, this section is based on literature.

10.5.1 Tipping points in the cryosphere

Arctic sea ice loss: The loss of Arctic sea ice, driven by atmospheric and ocean warming, reduces the Earth's albedo effect, its reflectivity, and influences weather patterns (Stroeve et al. 2012). This is likely to affect mid-latitude Northern Hemisphere weather by altering the position and strength of the jet stream and cyclogenesis (Previdi et al. 2021), resulting in

Figure 10.16: The risk of climate tipping points is rising rapidly as the world heats up

Note: Crossing a tipping point is categorized as "possible" beyond its minimum temperature threshold, "likely" beyond its central estimate, and "very likely" beyond its maximum temperature threshold. Additional tipping points not shown in the diagram include: Congo & SE Asia rainforest dieback, savanna & grassland degradation, dryland degradation, lake eutrophication-driven anoxia, lake invasive species, kelp forest collapse, Southern Ocean Overturning Circulation / Antarctic Overturning, Indian summer monsoon collapse / shift to low-precipitation states and ocean hypoxia.

Data source: McKay et al. (2022), UNEP (2024c), GEO-7 current trends scenario
Illustration: Modified from GLOBAÏA (2025)

more frequent and intense extreme weather events. Such changes could increase the persistence of particular blocking weather systems, which in summer are associated with droughts and heatwaves, and in winter, with extreme snowfall and low temperatures. Some models suggest that the Arctic could be ice-free during parts of the summer by 2030-2050 (National Snow and Ice Data Center 2024).

Ice sheet collapse: The rapid melting and collapse of parts of the Antarctic and Greenland ice sheets (Otosaka et al. 2023) are a major concern for global sea level rise. Between 2002 and 2020, 150 gigatons of Antarctic ice were lost per year. Under the Representative Concentration Pathway (RCP8.5), a high-emission scenario adopted by the IPCC, the melting of the Antarctic ice sheet could lead to global sea level rise of 34cm by 2100 and 1m by 2125 (DeConto et al. 2021). The RCP8.5 scenario projects a global mean surface temperature of 3.3 to 5.8°C, with a mean value of 4.3°C (IPCC 2021). This is slightly above the 3.9°C projected for the Current Trends scenario, which could be an underestimate if the Equilibrium Climate Sensitivity is higher than generally assumed (**Box 10.5**).

The Greenland ice sheet melt could contribute at least 27 cm to sea level rise by 2100, regardless of climate pathways (Box et al. 2022; Hanna et al. 2024). A complete melting of the Greenland ice sheet would increase sea level by 5-7 meters (Aschwanden et al. 2019), and a complete melting of the West Antarctic ice sheet could cause an additional 5-meter sea level rise (Chambers et al. 2022). Ice sheet collapse would be irreversible on societally relevant timescales, with profound consequences for coastal communities (Naughten et al. 2023).

Thawing of permafrost: Permafrost covers 15–25 per cent of the Northern Hemisphere and stores an estimated 1,700 billion tons of carbon (Miner et al. 2023). The loss of permafrost, driven by Arctic warming, would result in a feedback loop through reduced albedo and increased GHG emissions further accelerating warming. Permafrost thawing destabilizes landscapes, damages infrastructure, and poses risks to ecosystems and Arctic communities. Thermokarst thaw lakes now cover more than 1 million km² (Miner et al. 2023), and thawing is predicted to accelerate over the next 10 to 20 years. An abrupt thaw could result in the rapid release of carbon and methane within days to years (Miner et al. 2023).

Glacial retreat: Triggered by atmospheric warming and changes in precipitation, glacial retreat impacts freshwater availability and is likely to increase mountain hazards, including glacial lake outburst floods (Harrison et al. 2018) and rock slope failures (Shugar et al. 2021, Potter et al. 2023). These will have substantial negative impacts on local and regional infrastructure and energy systems (e.g. Li et al. 2022). Significant glacier losses are already occurring and accelerating, from 231 billion tons of ice per year between 2000 and 2011 to 314 billion tons per year between 2012 and 2023, reaching 548 billion tons in 2023 (Zempt et al. 2025). By 2100, between 49-83 per cent (Rounce et al. 2023) of global glacier mass could be lost, with between 34-46 per cent in the Alps by 2050 (Cook et al. 2023).

10.5.2 Tipping points in the biosphere

Amazon rainforest dieback: The Amazon rainforest is facing the risk of transitioning to a low tree-cover savanna landscape due to pressures of global temperature rise, drought, deforestation and increased intensity and frequency of wildfire (Boulton et al. 2022). The region is home to 2.2 million Indigenous peoples and stores the carbon equivalent of 15-20 years of global CO_2 emissions (Flores et al. 2024). Amazon rainforest dieback would have catastrophic impacts on biodiversity, alter local and regional climates, and transition the Amazon from a carbon sink to a carbon source, with some estimates suggesting the loss of tropical rainforest reaching over 50 per cent by end of the century (Nath, Nath and Chen 2024), and up to 47 per cent of Amazon forest at risk of ecosystem transition by 2050 (Flores et al. 2024). Amazon dieback could also expose approximately 6 million people to

Box 10.5: Climate tipping points may be reached much earlier than generally assumed

Several tipping points in the climate system are expected to be crossed within the next few decades if global temperature rise persists (**Figure 10.16**). While the exact timing is uncertain, the probability and severity of tipping points increase with warming. As a result, understanding the rate and extent of the temperature rise is crucial for assessing and preparing for the shifts that follow tipping points. Equilibrium Climate Sensitivity (ECS) measures the long-term change in global surface temperature after a doubling of the atmospheric CO_2 concentration (Forster et al. 2021). The precise estimates of ECS are uncertain because the strength and duration of the size of feedback mechanisms are not fully understood. Despite these uncertainties, most assessments show that the distribution of temperatures related to ECS is asymmetric, with a long tail on the higher end. Based on multiple lines of evidence, IPCC (2021) provides a best estimate of 3°C, with the likely range being 2.5°C to 4°C, and the very likely range of 2°C to 5°C. They concluded that it is virtually certain that ECS is larger than 1.5°C. and that increases over 5°C are still possible, albeit less likely. As a result, some climate scientists are concerned that the ECS is underestimated (Hansen et al. 2023), meaning that climate change is occurring faster and tipping points can be reached much earlier than currently forecasted (Ditlevsen and Ditlevsen 2023). This underscores the urgency to reduce emissions, as the potential consequences could be more severe than current models suggest.

the risk of heat stress (Alves de Oliveira et al. 2021) and cause an estimated US$1-3.5 trillion in economic damage over 30 years (Lapola et al. 2018).

Boreal and temperate forest dieback: Proximate drivers of boreal and temperate forest dieback include pest outbreaks and wildfires associated with climate change. Forest loss threatens biodiversity, increases carbon emissions and has complex climate cycle feedbacks (Magney and Pierrat 2025). The boreal forest is the largest biome on Earth and stores approximately one-third of the world's terrestrial carbon stocks (Rao et al. 2023). Earth System Models suggest that forest dieback at the southern margin could begin at around 1.5 C° of warming, becoming widespread at around 3.5°C, and approaching a biome-wide tipping point at around 4°C (Rao et al. 2023). In addition to being a carbon store, temperate forests contribute to local cooling (Lenton et al. 2023) and provide economically vital ecosystem services (Food and Agriculture Organization of the United Nations and the United Nations Economic Commission for Europe 2023). Hotter droughts, coupled with increased pest intensity and fire risks, are already transforming temperate forests into shrublands and grasslands in Australia and the south-central United States (Millar and Stephenson 2015).

Warm-water coral reef die-off: Warm-water coral reefs are among the most productive and highly biodiverse habitats, yet they are vulnerable to the impacts of warming seas, marine heatwaves, ocean acidification, and increased eutrophication. These stressors may shift biodiverse, coral-dominated ecosystems to low-diversity, macroalgae-dominated ecosystems (Rhoades, Brandt, and Witman 2023; Pearce-Kelly et al. 2025). This transformation would lead to the collapse of reef-associated commercial and artisanal fisheries, as well as increase coastal vulnerability to extreme weather events. Projections suggest that a 1.5°C warming could cause coral loss of 70-90 per cent, while a 2°C rise in global temperatures could result in a near-total loss of 99 per cent (Armstrong McKay et al. 2022, IPCC 2018, IPCC 2022c).

10.5.3 Tipping points in the ocean and atmospheric circulations

Shifts in the intensity and timing of monsoons: The monsoons are increasingly influenced by aerosols such as $PM_{2.5}$ in the atmosphere, GHGs, and land-use change (Seth et al. 2019), which significantly alter their timing and intensity. A substantial increase in rainfall intensity may lead to an expansion of vegetation in the Sahel and Saharan regions. However, this same weather pattern could push the desert into the African Mediterranean (Maghreb) region (Tian et al. 2023). In South-East Asia, 2˚C of warming could increase monsoon rainfall intensity (average rainfall in mm/h or mm/min) by 10 per cent (Yaduvanshi et al. 2021). These shifts would have negative socioeconomic consequences for regions dependent on rain-fed agricultural production or those with low adaptive capacity, and pose challenges for water resource management (Mutton et al. 2022).

Atlantic Meridional Overturning Circulation (AMOC) slowdown: The AMOC plays a critical role in the global climate system, transporting heat to northern latitudes and regulating the oceans' thermohaline circulation. Recently, the AMOC has shown signs of slowing down (Caesar et al. 2018; Zhu and Liu 2020), likely due to an increased influx of freshwater into the North Atlantic, raising concerns about a potential rapid collapse. This would produce a range of large-scale climate impacts, including cooling across the Northern Hemisphere, an expansion of Arctic sea ice, and a southward shift of the Intertropical Convergence Zone (Ma et al. 2024). Further effects would include a likely rearrangement of tropical monsoon systems (Ben-Yami et al. 2024), heatwaves in eastern Europe (Meccia et al. 2025), as well as accelerated ice melt in Antarctica and subsequent global sea level rise.

10.5.4 Interactions and feedback loops

One of the characteristics of global environmental change is the interaction among crises, generating positive feedback loops that worsen their impacts. These interactions are particularly evident among climate change, land degradation and biodiversity loss. For example, permafrost degradation driven by warming and thawing can alter landscape structure, disrupt vegetation dynamics, and affect nutrient cycling. Crucially, these processes also release stored CH_4 and CO_2 (Schuur et al. 2015), accelerating climate change. Similarly, deforestation and climate change both contribute to land degradation. As land degrades, it has less biomass and lower productivity, potentially shifting from a carbon sink to a carbon source (IPCC 2019).

10.6 Socioeconomic implications under current trends

Human well-being and socioeconomic development are shaped by a range of interdependent social, cultural, economic, political, and environmental factors, with multiple negative implications resulting from the global environmental crises (Chapter 7). This section discusses projected progress towards socioeconomic SDG targets under the Current Trends scenario (10.6.1-10.6,4), as well as the economic impacts of the global environmental crises (10.6.5). Since the impacts of global environmental crises on human well-being and the economy could only be partially modelled, the discussion also draws on existing literature.

Overall, since 2020, the progress toward the SDGs has slowed (Malekpour et al. 2023; Sachs, Lafortune and Fuller 2024). Under the Current Trends scenario, human well-being is projected to improve generally; however, none of the well-being-related SDGs are projected to be fully achieved, not even by 2050 (**Figure 10.17**). This is in line with other analyses and assessments (Moyer and Hedden 2020; van Vuuren et al. 2022; Fu and Zhang 2024; Sachs, Lafortune and Fuller 2024; United Nations Department of Economic and Social 2024). Furthermore, projected gains in humanwell-being are increasingly threatened by the intensifying global environmental crises, affecting health, food systems and livelihoods.

The projected improvements in well-being are unevenly distributed, with some vulnerable communities and groups experiencing slower progress and disproportionately worse effects from the environmental crisis. Those most affected include women, the elderly, young children, ethnic minorities, and individuals with pre-existing health conditions (7.2.5). In Indigenous populations, the impacts of poverty, environmental pressures, and lack of access to basic public services such as education, health, and social protection are particularly felt by women and girls (Carmen 2017; Bryson et al. 2021; Vecchio et al. 2022).

10.6.1 Basic material needs

Basic material needs include nutrition (SDG2), access to safely managed drinking water sources and sanitation (SDG6), and access to clean cooking fuels and technologies (SDG7) (**Figure 10.17**).

As of 2023, 9 per cent of the global population was estimated to be undernourished (FAO 2023). In line with the projected increase in average per capita food intake (section 10.3.2), the total number of undernourished people is projected to decline by 60 per cent from 2020 to 2050. However, this progress is insufficient to meet SDG 2.1, and hunger hotspots are likely to persist, particularly in Africa. Children under 5 are especially vulnerable. While today children make up roughly 16 per cent of the undernourished population, this share is projected to increase to 20 per cent by 2050.

Despite overall improvements, progress in reducing undernutrition will be hindered by environmental crises to varying extents across regions and contexts. Broadly, climate change, land degradation, and water stress affect the food supply by reducing agricultural yields (Vermeulen, Campbell and Ingram 2012; **Box 10.2**), altering marine productivity (Vermeulen, Campbell and Ingram 2012; Watts et al. 2021; Palacios-Abrantes et al. 2022; IPCC 2023a), and causing losses from flooding, wildfires, and other extreme events (Vermeulen, Campbell and Ingram 2012; Pacetti, Caporali and Rulli 2017; Rahman and Di 2020). For example, scenario studies show that climate change could reduce per-person food availability by 3.4 per cent (Springmann et al. 2016), and could increase the population at risk of hunger by 24 million in 2050 (Hasegawa et al. 2018). Furthermore, an increased frequency of extreme events could push this number higher by 11 to 36 per cent by 2050 (Hasegawa et al. 2021). Women and girls are often hit harder by food insecurity due to limited access to financing and resources and intra-household inequalities, where they are expected to eat last (Agarwal 2018). Moderate and severe food insecurity, as measured by the Food Insecurity Experience Scale, is projected to be two percentage points higher for women than for men worldwide.

As of 2022, 27 per cent of the world's population lacked access to safely managed drinking water sources, of which around 5 per cent relied on unimproved sources, and 43 per cent lacked access to safely managed sanitation (United Nations Children's Fund [UNICEF] and World Health Organization 2023). Access to safe water and sanitation is crucial for human health, particularly for young children (Nounkeu and Dharod 2021; 6.6.4). Women and girls are disproportionately affected by a lack of access to safe water and sanitation (Kayser et al. 2019; Pouramin et al. 2020). While access levels is projected to improve, by 2050 hundreds of

Figure 10.17: Trend in selected socioeconomic SDG targets

Source: IFs Model

Credit: Great_bru/Envato

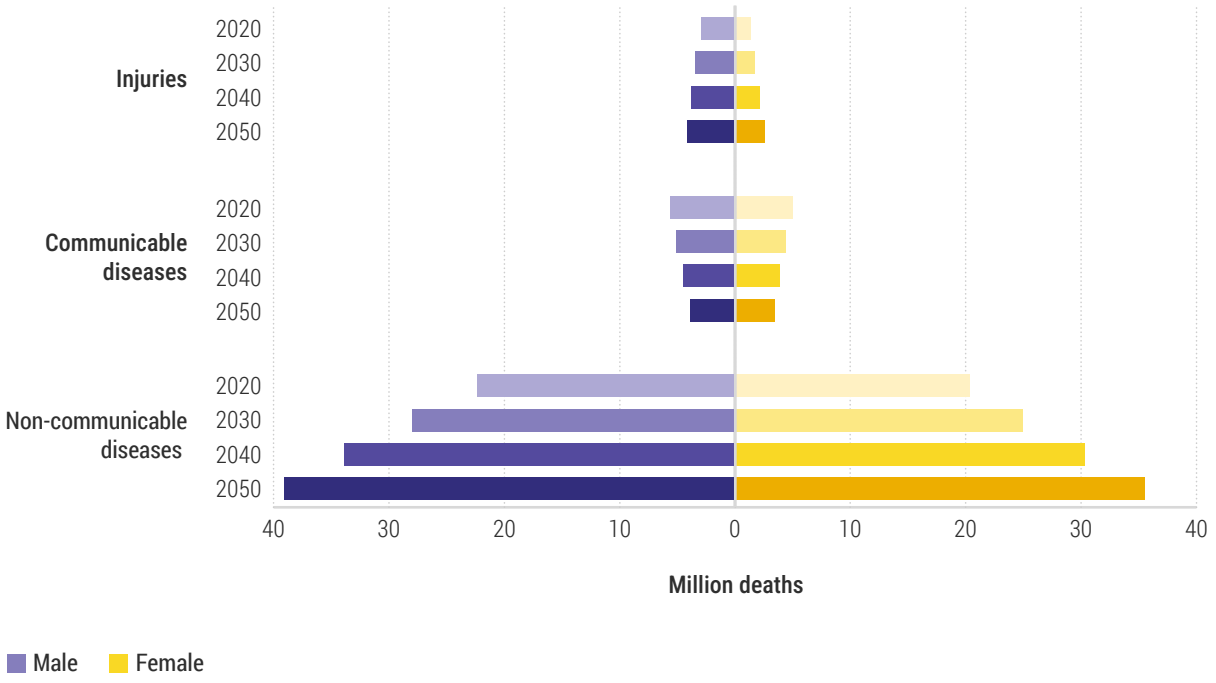
millions would still lack access to improved water and sanitation services, failing to meet SDG 6.1 and 6.2.

In 2023, 9 per cent of the global population, including 16 per cent of the rural population, lacked access to electricity. Additionally, around one-fourth of the global population lacked access to clean cooking fuels and technologies (International Energy Agency [IEA], International Renewable Energy Agency [IRENA], United Nations Statistics Division, World Bank, World Health Organization 2024; 7.2.7). Electricity is essential for human development (Fuso Nerini et al. 2017; United Nations Department of Economic and Social Affairs 2014). Lack of access to clean cooking fuels increases indoor air pollution, generating health issues (3.5; 10.6.2), which disproportionately affect women and children (Martin, Hollingsworth, and Ramanathan 2014; Kuhn et al. 2016). Although access to modern energy is projected to improve in the Current Trends scenario by 2050, 5 per cent of the global population and 10 per cent of the rural population would still lack electricity access, and 7 per cent of the global households would still rely on traditional cookstoves, failing to meet SDG7.1.

Global environmental crises will increase pressure on electrical grids due to hotter weather and extreme events (Vermeulen, Campbell and Ingram 2012; Panteli and Mancarella 2015). Furthermore, rising temperatures and extreme weather events increase the demand for heating, cooling, and disaster recovery, leading to higher costs and energy insecurity, particularly among low-income households. This, in turn, can limit digital access, hinder education, and reduce access to clean cooking (Jessel, Sawyer and Hernandez 2019; Bezgrebelna et al. 2021).

10.6.2 Good health

Under the Current Trends scenario, health outcomes are projected to improve by 2050, with average life expectancy rising from around 73 years in 2020 to 78 by 2050 (Sellers 2020). However, many health-related SDGs will remain unmet. For example, SDG target 3.2



on neonatal and under-5 mortality is projected to be met globally only after 2040, while low- and lower middle-income countries may lag by another decade (**Figure 10.17**), mainly due to inadequate provision of basic material needs (Lucas et al. 2019).

In 2020, communicable diseases – including AIDS, diarrheal disease, malaria, respiratory infections, and others – made up roughly 18 per cent of total deaths worldwide, with nearly half occurring in low-income countries. Under the Current Trends scenario, nutrition, health systems, and improved infrastructure in terms of water and energy are projected to reduce the burden of communicable diseases (**Figure 10.18**). However, the global environmental crises may impede this progress. Improved nutrition, access to water and clean cooking reduce diarrheal diseases and respiratory infections (Prüss-Ustün et al. 2014; Cohen et al. 2017; Prüss-Ustün et al. 2019; Chen et al. 2023; Sen et al. 2023), while warming and shifting precipitation patterns increase the risk of vector-borne diseases, like malaria (Rocklov and Dubrow 2020; Watts et al. 2021).

In 2020, non-communicable diseases, including heart disease, diabetes, digestive disease, cancer, respiratory disease, and others, accounted for 74 per cent of deaths globally. By 2050, this share is projected to exceed 80 per cent (**Figure 10.18**), driven by increasing affluence and aging populations. The global environmental crises are likely to increase premature death from non-communicable diseases further. Air pollution, both urban (10.4.2) and indoor from traditional cookstoves (10.6.1), contributes to an increased incidence of respiratory disease (Faizan and Thakur 2019; Pratiti et al. 2020). In the Current Trends scenario, urban air pollution alone, resulting from $PM_{2.5}$, could result in an estimated 4 million deaths in 2050, similar to 2020 levels (10.4.2). Mining activities increase exposure to toxic dust (González 2024) and contaminate freshwater, leading to bioaccumulation of toxins and heavy metals, like mercury, contributing to chronical diseases, such as higher rates of cancer, heart and lung disease, and neurological damage (Fuller et al. 2022). Rising temperatures increase the risk of heat stroke, heat stress, cardiovascular disease (Green et al. 2019; Watts et al. 2021), as well as mental health issues (Byun et al. 2024).

In 2020, 8 per cent of deaths globally were attributed to injuries. The injury burden is projected to increase slightly by 2050 (Figure 10.18), due to demographic and epidemiological changes, including population growth, development, urbanization, and a rise in traffic accidents (Haagsma et al. 2020). Global

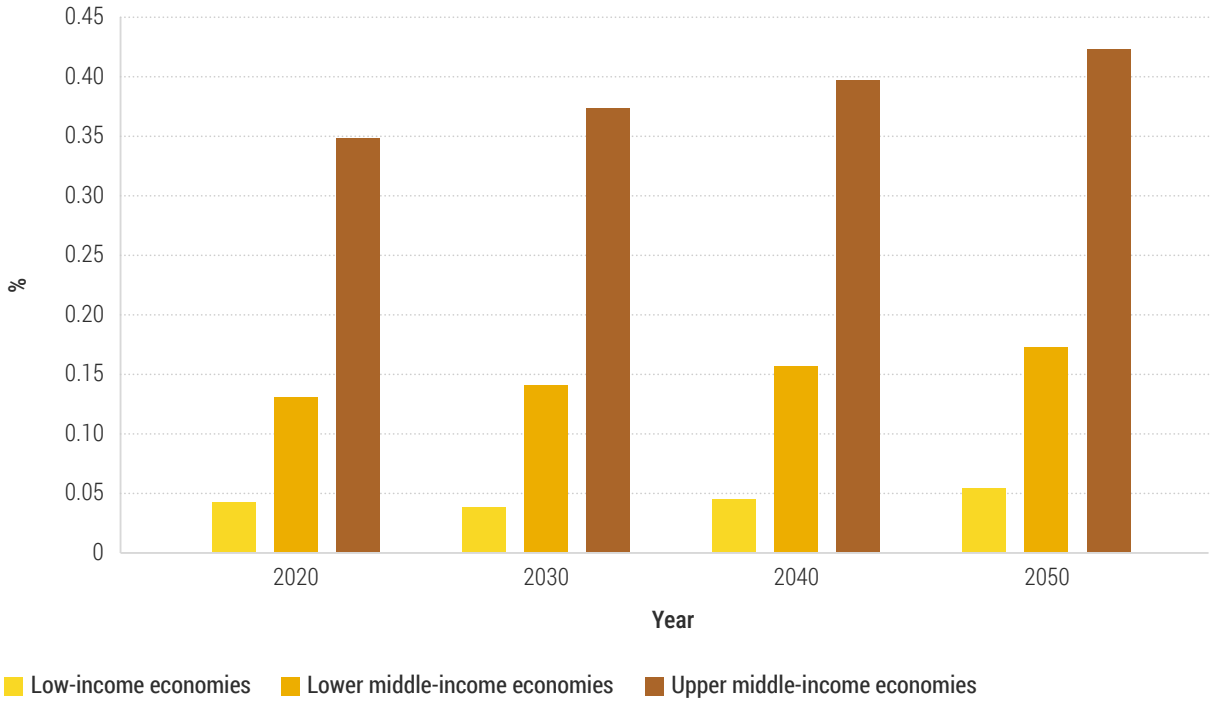
Figure 10.18: Global mortality by overall category of cause and sex

Source: IFs Model

environmental crises may exacerbate injuries resulting from extreme events, such as wildfires, storms, and flooding, and contribute to an increase in mental health problems in the general population (Rataj, Kunzweiler, and Garthus-Niegel 2016; Cruz et al. 2020). **Box 10.6** describes implications of the global environmental crises on the mental health of Indigenous Peoples.

10.6.3 Fair and just societies

In 2020, the COVID-19 pandemic led to a rise in the global poverty rate for the first time in decades (Moyer et al. 2022). While poverty reduction has resumed since 2020, progress has been slow (World Bank 2024). Under the Current Trends scenario, as economies grow, the poverty rate is projected to fall, but not fast enough to meet SDG target 1.1 by 2030 or even by 2050 (**Figure 10.17**). While the overall income inequality is projected to remain stable (Rao et al. 2018), disparities across income groups persist (**Figure 10.19**). Upper-middle-income economies are slowly converging with high-income economies in terms of GDP per capita. However, by 2050 their average income would still be less than half of that of the high-income countries. In low-income countries, average GDP per capita as a per cent of that in high-income countries is projected to improve only slightly, from 4 per cent in 2020 to 5 per cent by 2050.



Women and girls are disproportionately affected by poverty, especially as young adults (Marley and Desai 2020). In 2020, the global female poverty rate is 0.6 percentage points higher at US$2.15/day, the extreme poverty line, 5 percentage points higher at US$3.65/day, a poverty line more relevant in lower-middle-income countries, and 10 percentage points higher at US$6.85/day, a poverty line more relevant for upper-middle-income countries. Under the Current Trends scenario, these gaps are projected to narrow in the coming decades, but they are not projected to close. Slower progress will likely also affect Indigenous Peoples and their communities, who often experience worse outcomes compared to non-Indigenous

Box 10.6: Implications of the global environmental crises on the mental health of Indigenous Peoples

For many Indigenous cultures, health and mental well-being are not individual matters, but rather a reflection of respectful, reciprocal relationships with their environment (Redvers 2020; Redvers et al. 2023). Moreover, maintaining a strong attachment to places, preserving cultural practices, institutions, and languages are crucial for effective mental health care in these communities (Redvers 2020; Redvers et al. 2023). However, mental health care of Indigenous Peoples has been neglected globally (Incayawar and Maldonado-Bouchard 2009; Nelson and Wilson 2017; Page et al. 2022; Subica et al. 2024), with many reports identifying colonization and historical trauma as key drivers to the current mental stress challenges (Kirmayer, Brass and Tait 2000; Matthews et al. 2023). The ongoing threats to Indigenous sovereignty and rights, often driven by environmental degradation, further strain mental well-being, especially where healthcare access remains limited (Fernández-Llamazares et al. 2020).

Environmental degradation, industrial resource extraction and pollution on Indigenous lands often harm the mental health of Indigenous communities by eroding Indigenous Knowledge and disrupting their culture (Ninomiya et al. 2023). Climate change stressors and impacts, such as extreme weather events, including storms, flooding, heatwaves, and changes in seasonality, as well as drought, sea ice changes, wildfires, and vegetation shifts, are often linked to feelings of loss, worry, anger, and sadness (Middleton et al. 2020). Long-term exposure to the consequences of climate change among Indigenous populations can affect the fundamental pillars of mental health, including food and water insecurity, community cohesion, and traditional ways of life (Middleton et al. 2020; Brubacher et al. 2024). Among the Shawi people in the Peruvian Amazon, a decline in wild animals in their territory, seen as a disruption of environmental balance or a lack of respect for nature, has led to feelings of anxiety and guilt (Arotoma-Rojas et al. 2022). In the Canadian Arctic, climate-induced displacement among the Inuit leads to the erosion of identity and culture, contributing to environmental emotional distress (Ayeb-Karlsson, Hoad, and Trueba 2024).

Figure 10.19: Relative shares of GDP per capita compared to high-income economies

Source: IFs Model

populations (World Bank 2011; Hall and Patrinos 2012; Anderson et al. 2016).

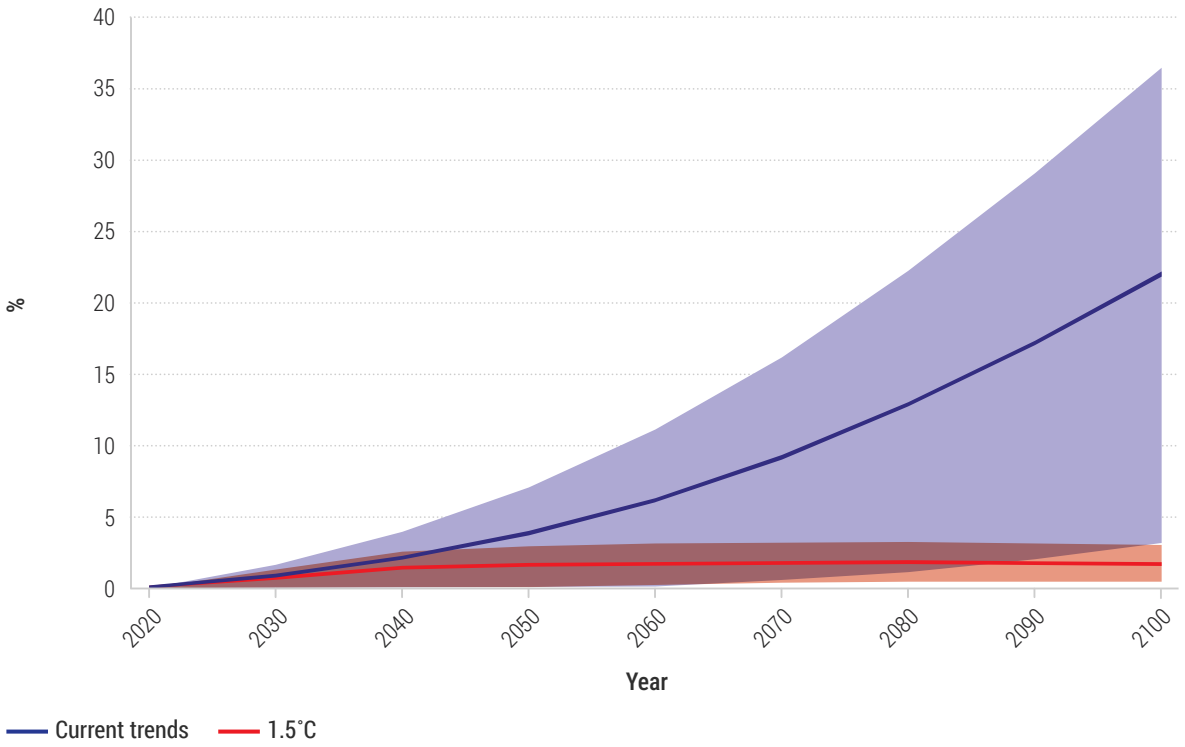
Global environmental crises are likely to hinder poverty reduction by slowing economic growth and exacerbating inequality, both between countries (Mendelsohn, Dinar, and Williams 2006; Ahmed, Diffenbaugh, and Hertel 2009; Diffenbaugh and Burke 2019) and within countries (Hallegatte and Rozenberg 2017; Paglialunga, Coveri, and Zanfei 2022). Poor households will be especially affected by rising food prices (Hertel, Burke and Lobell 2010; Hallegatte and Rozenberg 2017), while farming and rural households could be hurt by changes in agricultural productivity. Increased health risks could lead to lost working days and higher medical costs (Hallegatte and Rozenberg 2017), while environmental disasters could result in the loss of assets and income, especially for vulnerable populations (Heltberg, Oviedo, and Talukdar 2015). For example, other scenario studies show that climate change alone could push an additional 32 to 132 million people into poverty by 2030 (Jafino et al. 2020), and between 40 and 78 million by 2050 (Moyer et al. 2023).

10.6.4 Human security

Human security measures the presence of violent conflict between groups of people or individuals and includes both intrastate and interstate armed conflict (Hughes et al. 2014). Under the Current Trends scenario, the probability of civil war onset, used here as a proxy for human security, is projected to decrease over time (**Figure 10.17**). This decline is generally attributed to improvements in human development, stronger government institutions, greater international economic integration, and positive neighbourhood effects that underlie this scenario. However, even with this reduced likelihood of conflict, the world is not on track to meet the SDG 16.1 target of eliminating conflict-related deaths.

There are significant uncertainties surrounding these projections – even without considering the global environmental crises (Goldstone et al. 2010; Hegre, Karlesen, and Strand 2013; Cederman and Weidmann 2017; Bowlsby et al. 2019; Hegre, Nygård, and Landsverk 2021). It is essential to acknowledge that models can exhibit varying behaviour over time, and that overreliance on a single model can be misleading. Predicting the onset of conflict is more challenging than estimating the magnitude of conflict. The model used here can be compared with other forecasts of conflict onset, including Goldstone et al. (2010) and Hegre et al. (2013).

Global environmental crises may exacerbate conflict through changes in resource availability and by driving migration, particularly due to the loss of food and livelihoods (7.2). However, evidence of the effects of climate change on the onset of civil war is mixed (Mach et al. 2019). Likewise, projections of armed conflict between states are highly uncertain (Moyer 2024). Changes in socioeconomic patterns and climate change mitigation strategies could lead to geopolitical shifts, either increasing or decreasing the likelihood of interstate armed conflict (Moyer 2024). However, while improvements in human security overall are projected to improve, any armed conflicts have significant negative implications for human development (United Nations Development Programme [UNDP] 2022).



10.6.5 Economic impact

The scientific literature unequivocally emphasize that further worsening of global environmental crises will inevitably lead to rising economic costs (Piontek et al. 2021; IPCC 2022a). The costs of inaction or insufficient action are already evident (Funk et al. 2019; Rimi et al. 2019; Yiou et al. 2020; van Oldenborgh et al. 2021; Tavoni et al. 2024). A range of projections conclude that future GDP growth will be lower than the Current Trends scenario estimates when including the costs of climate change and environmental degradation (Burke et al. 2015; Howard et al. 2017; van der Wijst et al. 2023).

Under the Current Trends scenario, the economic impacts or damage costs from climate change are projected to increase over time (**Figure 10.20**), with a non-linear intensification in the second half of the century. This projection is associated with high uncertainties. The median estimate of global GDP loss is projected to increase to 4 (0-7) per cent in 2050 at US$9.5 trillion per year, growing further to 22 (3-37) per cent in 2100 at US$133 trillion per year. In contrast, a transformation pathway that limits global temperature rise to 1.5°C (11.5), could keep median GDP losses below 2 per cent throughout the century.

These estimates of global GDP loss include, among others, climate-related impacts from agriculture, energy, labour supply, and flooding from rivers and sea-level rise. However, they do not account for other essential aspects, such as climate-change-induced health impacts,

Figure 10.20: Global aggregate GDP losses from climate impacts

Note: Solid lines indicate median estimates of the damage functions. The ranges are the 5th-95th percentiles of the damage functions.

Source: MIMOSA model

biodiversity losses, or tipping points (10.5), which are harder to quantify. Including these factors would likely result in even higher projected GDP losses.

The broad uncertainty range in this projection aligns with the contribution of Working Group 2 to the 6th Assessment report of the IPCC (Rose et al. 2022) and recent studies using empirical data of economic impacts of climate change (Burke et al. 2015; Kalkuhl and Wenz 2020; Piontek et al. 2021). Studies based on empirical GDP growth data and econometric models (Burke et al. 2015) tend to estimate higher economic costs. In contrast, bottom-up studies that account for sector-specific economic damages, such as presented here, tend to estimate lower costs (Takakura et al. 2019).

Beyond climate change, the other global environmental crises are also expected to cause significant economic damage. Johnson et al. (2020) estimate that, under a similar scenario as the Current Trends scenario, the annual GDP loss could reach US$478 billion by 2050, resulting in a total loss of US$9.87 trillion in real GDP by mid-century. The Climate Policy Initiative (2024) estimates cumulative losses of US$1,266 trillion between 2025 and 2100. For biodiversity, a decline in selected ecosystem services could result in a global real GDP loss of US$90-225 billion by 2030 (Johnson et al 2021). Current annual cost of declining ecosystem functionality is estimated at US$5 trillion to US$25 trillion (Costanza et al. 2014; Kurt et al. 2021). Regarding land degradation, the FAO and the Intergovernmental Technical Panel on Soils (2015) highlight that, in response to global soil erosion, annual expenditures range from US$33 billion to US$60 billion for nitrogen and from US$77 billion to US$140 billion for phosphorus applications.

Table 10.1 offers an overview of the cost estimates from the literature related to inaction or inadequate action across various sectors under current

Table 10.1: Cost estimates associated with inaction or inadequate action across various sectors

Sector	Estimated costs	Unit
Agriculture (crop production)	S$80-120 billion lost annually to 2100 (IPCC 2022b; FAO 2023) US$15.3 billion lost annually in real GDP terms due to pollinator habitat reduction and US$19 billion lost annually in real GDP terms due to water scarcity for irrigation alone to mid-century (Johnson et al. 2020)	Value of crop output at risk due to extreme weather events, salt-induced land degradation, pollinator loss, water scarcity for irrigation, increased pests and disease.
Disaster risk reduction	US$327 billion of reduced GDP per year to 2050 (Johnson et al. 2020)	Lost GDP from reduced productivity in coastal areas linked to the loss and depletion of capital and productive assets. This decline results from exposure to inundation due to changes in terrestrial and marine habitats that normally protect the coast from erosion and flooding.
Energy	US$50-80 billion annually to 2100 (IPCC 2022b; IEA 2023) US$12 trillion to 2050 (IRENA 2017)	Value of damage to energy infrastructure and asset stranding following extreme weather events and projected increasing energy demand, in some instances.
Forestry	US$7.5 billion as net annual loss in real GDP to 2050 (Johnson et al. 2020)	Reduced productivity and timber production as a result of changes in biomass linked to land use, temperature and precipitation changes.
Health	US$60-150 billion annually to 2100 (Romanello et al. 2023) US$12.5 trillion by 2050 (World Economic Forum [WEF] 2024) Up to US$18-25 trillion annually by 2060 for air pollution-related deaths and US$2.2 trillion by 2060 for diseases caused by air pollution alone, using constant 2010 US$ and purchasing power parity exchange rates (OECD 2016)	imate-induced productivity loss, due to detrimental health outcomes, and cost of treatment. As for air pollution, costs include the annual economic losses due to premature deaths and costs associated with treating pollution-related illnesses.

Table 10.1: Cost estimates associated with inaction or inadequate action across various sectors (cont.)

Sector	Estimated costs	Unit
Labour	US$2.4 trillion lost by 2030, with limited global warming to 1.5°C above preindustrial levels by the end of the century (International Labour Organization [ILO] 2019)	alue of lost working hours due to heat stress. With further environmental degradation, agricultural workers will be the worst affected and will account for 66 per cent of global work hours lost due to heat stress in 2030 (Montt, Fraga and Harsdorff 2018).
Livestock	US$10-13 billion lost by 2050 due to a 7-10% decrease in livestock numbers at 2°C, in turn, caused by decreased forage productivity (Boone et al. 2018) US$22-38 billion lost annually in dairy and beef production by 2100 under SSP5 (IPCC 2022a)	Direct losses resulting from heat stress affect livestock mortality and productivity, and indirectly impact forage availability and quality.
Tourism	S$80-120 billion lost annually to 2100 (Layne 2017; United Nations World Tourism Organization [UNWTO] 2023)	Value of tourism revenues at risk due to extreme weather events and sea-level rise
Urban areas and infrastructure	S$100-200 billion annually to 2100 (United Nations Office for Disaster Risk Reduction [UNDRR] 2019; IPCC 2022b	Costs of damage repairs due to an increased frequency and intensity of extreme weather and other climate-related events.
Water resources	S$20-40 billion annually to 2100 (IPCC 2022b)	Implication of reduced water availability due to increasing incidences of drought.

trends-like scenarios, primarily SSP2. While these estimates aim to capture the complex economic impacts, uncertainties remain, as reflected in the broad ranges presented. Moreover, differences in metrics and methodologies mean that these studies cannot be directly compared; yet, they unambiguously point to the economic risks of no or inadequate responses to the global environmental crises.

Quantifying the costs of no or insufficient action is a complex task, and estimates vary widely due to differences in the variables being considered, models used, assumptions, and timeframes. Additionally, some costs are not quantified in the literature and are either explored qualitatively or omitted from modelling exercises due to data deficiencies or other challenges. This includes the cost of global environmental crises on Indigenous Peoples and their communities. The literature indicates that as land degradation, pollution, and climate change affect traditional food practices, Indigenous Peoples require more expensive equipment and tools, and increasingly rely on store-bought foods to adapt (Norton-Smith et al. 2016). The economic effect of displacement from Indigenous land remains difficult to model at this time (Ram and Shahzar 2024).

10.7 The need tobreak with current trends

The scenario analysis clearly shows that the world is not on track to achieve the globally agreed goals related to the global environmental crises, including key goals and targets of the Paris Agreement, the Kunming-Montreal Global Biodiversity Framework, and the United Nations Convention to Combat Desertification. The global environmental crises risk triggering major shifts in the Earth's systems, including accelerated rates of change and the potential for tipping points to occur. Furthermore, they hinder progress on socioeconomic SDG targets by impeding food systems, human health, and livelihoods.

The costs of inaction or insufficient action, both economic and social, are already evident and are projected to increase further. Addressing these environmental crises and achieving internationally agreed goals requires a fundamental shift from current trends, including the decoupling of human development from environmental degradation. This requires transformation of the economic and finance, food, energy, and materials/waste systems, as well as changes in the way the environment is managed. Transformation Pathways towards achieving globally agreed goals are discussed in Chapter 11.

Chapter summary

Credit: image Envato

The GEO-7 target-seeking scenarios illustrate that achieving the ambitious environmental and societal goals as agreed upon in multilateral agreements is possible, but only if immediate, unprecedented and coordinated transformations take place across the economy and finance, energy, food, materials/waste, and environmental systems (*well established*) {11.2}. The scenarios describe a complete transformation of systems for supply, demand, consumption, and provision of services. The different pathways show a range of possible and coherent strategies across the systems to achieve the goals {11.6}. Challenges lie in rapid implementation, in coordinating with actors across diverse systems, sectors, and regions, and in gaining societal acceptance of specific solutions, such as carbon dioxide removal, changes in consumption patterns and human behaviour, among others, without exacerbating existing or creating new forms of inequality and injustice {11.7}.

There are still several pathways to achieving the intended goals. The GEO-7 *Behaviour-focused Transformation Pathway* and the *Technology-focused Transformation Pathway* assessed here achieve the goals based on different combinations of social and technical shifts, but both have major implications for energy, materials/waste and food systems. Both Transformation Pathways depend on effective governance and strong institutions at multiple levels {11.5, 11.7}, high levels of technology development, and well-regulated markets where prices reflect the true environmental and social cost of goods and services. However, they differ in the relative importance of regulation and pricing instruments, type and purpose of technological development, and the overall emphasis on behavioural changes towards sufficiency, or technological solutions towards efficiency. Aligned to these overall emphases, specific solutions or strategies are adopted in the transformation of each system {11.2, 11.3}. By elaborating on the results of these two pathways, it is possible to identify similarities and contrasts between them, highlighting important synergies and trade-offs between the different systems.

Abandoning inefficient and unnecessary use of resources creates multiple synergies across the systems, helping to address the global environmental crises and improve human well-being (*well established*) {11.6}. For instance, reducing overall energy demand makes it significantly easier to decarbonize the energy system {11.3.1} and meet climate goals {11.4.1}. This can be aided by lowering energy and material demands for shelter, mobility and other goods and services. This also reduces

the requirement for vast amounts of renewable energy technologies, and related critical materials {11.3.3}, as well as the dependence on large-scale negative emission technologies {11.4.1}. Less need for biomass and bioenergy also reduces pressures on land, biodiversity and water. Shifting dietary patterns away from excessive amounts of animal products towards plant-based foods, cultured meat, and healthy food-intake levels also reduces pressure on the land system {11.3.2}. This can free up large areas currently dedicated to animal feed production, while also reducing greenhouse gas emissions related to industrial-scale livestock production. This makes it easier to achieve climate, biodiversity, land degradation and pollution goals, and helps make the land system a net carbon dioxide sink, further mitigating climate change and land degradation {11.4.1, 11.4.3}.

Transforming human systems to address the global environmental crises has multiple benefits for people, but additional measures are necessary to fully achieve well-being goals (*established but incomplete*). Ending hunger and establishing universal access to clean water, mobility, adequate housing, clean energy, clean air, and appropriate changes in diets have significant benefits for human health, poverty reduction and human security {11.5}. However, to achieve the full range and depth of socioeconomic goals, societal transformations are necessary. For example, eliminating hunger will require direct support for the poorer parts of society. Addressing global environmental crises without simultaneously addressing unacceptable levels of inequality and inequity, regional disparities, and failures in social security and health provision may lead to significant trade-offs and social strife. Thus, all system transformations must occur in an equitable and inclusive manner, including Indigenous populations and local communities. Social, political and cultural change must necessarily accompany the transformations {11.5, 11.6, 11.7}.

An immediate, sustained and just transformation of the energy system is necessary to meet climate goals and will enable the required transformations of other systems {11.3.1}. A sustained increase in renewables and a substantial reduction of unabated fossil fuel technologies by 2050 are a prerequisite for meeting climate goals {11.4.1}. The electrification of final energy demand by 2050 forms part of both *Transformation Pathways*, more than doubling from approximately 20 per cent to almost 50 per cent by 2050. This highlights the importance of investing in reliable and interconnected infrastructure, combined with massive investment in renewable energy capacities, power storage, and new energy consumption technologies, such as electrified transport and heat pumps, among others. Given the urgency of meeting climate goals, both pathways also rely on some form of carbon dioxide removal techniques, but to differing extents. Reducing energy demand, by changing consumption patterns and increasing efficiency, makes increased electrification rates easier to achieve. It also reduces dependence on technologies such as carbon capture and storage, whose large-scale deployment is both uncertain and expensive and may pose significant risks. The presented transformation in the energy system limits energy demand, reduces resource use and contributes to meeting air pollution, food access, biodiversity and water scarcity goals {11.3.2, 11.3.3, 11.4.2, 11.4.4, 11.4.6}.

Food system measures such as improved agricultural practices, diet change, and food-waste reductions can prevent continued natural land conversion and degradation (*well established*) {11.3.2}. Possible food system transformations range from highly intensified systems in line with the land-sparing paradigm, to mixed systems combining Indigenous Knowledge, Local Knowledge and scientific knowledge. Reduced demand for agricultural products through changes in dietary patterns and less food waste can alleviate pressure on the agricultural system, decreasing agricultural land use. Curtailing the consumption of meat has the greatest effect, vastly reducing the use of land for pasture and feed, improving biodiversity {11.4.4}, reducing surplus manure and associated pollution {11.4.5}, and providing significant health benefits {11.5.2}. These changes, together with improved irrigation management, can also vastly reduce water stress while still providing adequate irrigation {11.4.6}. Furthermore, the abatement of agricultural methane and ammonia emissions helps reduce atmospheric pollution {11.4.2}.

Protection of existing ecosystems, restoration of degraded lands and improved land management are crucial to preserving biodiversity and increasing carbon storage (*established but incomplete*) {11.3.4}. Both pathways envision an increase in protected areas, ranging from 30 per cent with strict protection, called land-sparing, to 50 per cent with more mutually beneficial relations between humans and nature, called land-sharing. Increasing protected areas helps prevent the conversion of natural land and improves the possibilities of tackling biodiversity loss {11.4.4}. Furthermore, preserving and expanding natural lands allows them to act as important carbon sinks,

Credit: vectorfusionart/Envato

which helps to mitigate climate change {11.4.1}. However, this protection needs to be supported by improvements in agricultural production, including agroecology and agroforestry, and in distribution. This will help avoid food deprivation in vulnerable populations, which may arise from increased competition for land {11.3.2, 11.5, 11.6}.

The benefits of transformation vastly outweigh the upfront costs due to the avoided damages from climate change, with benefits surpassing US$ 20 trillion per year by 2070 (*established but incomplete*). Changes in consumption and production due to the transformations needed across all systems will cost approximately US$ 1 trillion to US$ 3 trillion per year until 2050, equivalent to a loss of approximately 1.5 per cent of projected global economic activity. However, after 2050, the economic damage from climate change becomes increasingly severe {10.6.5}, leading to a loss of 6 per cent of potential future gross domestic product by 2070 and increasing to over 25 per cent by 2100. This is equivalent to the benefits of the transformation being approximately US$ 20 trillion per year in 2070, to over US$ 100 trillion per year by 2100 {11.5.5}. Additional economic benefits of the transformation can be expected from improved access to food and energy services and positive effects on work, productivity and social well-being, as well as benefits from improved ecosystem services.

The associated transformations present a number of important synergies. However, to avoid potential trade-offs, the correct enabling conditions need to be identified and implemented (*established but incomplete*) {11.6}. While the presented pathways can meet multiple goals across environmental and human systems, bringing them to fruition will require broad negotiation on potential trade-offs. Given the scale of the transformation needed, inevitably there will be segments of society and interests that will be significantly affected. This makes it particularly important to ensure that the opportunities that arise are harnessed and distributed equitably and that the costs are shared in a just manner. The transformation depends on the presence of specific conditions including effective governance and policymaking; appropriate legal frameworks; increased predictability of policies to ensure adequate engagement of stakeholders including industry, civil society, and others; and inclusion of various forms of knowledge such as Indigenous, local and scientific. Furthermore, protecting those who are energy and food-insecure and fostering legitimate and well-functioning institutions to mediate social and political friction when implementing the proposed solutions is also required.

11.1 Introduction

As the *Current Trends Scenario* demonstrates, continuing current trends across the economic and financial, energy, food, resource, and environmental systems is failing to achieve many internationally agreed environmental goals and related SDGs. This pathway is even amplifying negative trends in the global environmental crises towards 2050 (Chapter 10). In this chapter we will explore two target-seeking scenarios, the *Behaviour-focused Transformation* and the *Technology-focused Transformation*. They represent alternative Transformation Pathways that could meet a set of internationally agreed environmental goals while guaranteeing food security and universal access to energy and water. The goals and adopted targets are indicated in **Table 9.1** and discussed in more detail in Chapter 9.

Importantly, these deliberately constrained target-seeking scenarios are not predictions, and no likelihood is attached to them, nor do they present or evaluate specific policy measures. Instead, they are archetypes of different possible transformations. As such, they illustrate – in general terms – the type and extent of action needed to meet the goals, the critical choices involved, the associated synergies and trade-offs, and the possible challenges and opportunities.

Section 11.2 presents the narratives for the target-seeking scenarios, following the methodology and general assumptions detailed in Section 9.4. Section 11.3 presents quantitative results for each system, while Sections 11.4 and 11.5 present, respectively, the environmental and socioeconomic implications of the two pathways. Finally, Sections 11.6 and 11.7 discuss some considerations about the synergies, challenges and opportunities presented. This chapter does not discuss the social or political feasibility of the Transformation Pathways. Instead, it aims to present quantitative and qualitative context on the extent of the required transformation and important underlying dynamics. Subsequently, Chapters 12–18 build upon the insights presented here and detail specific "solution pathways" that describe how to implement the transformation of each system, such as the necessary conditions, actors, policies and measures. Then Chapters 19 and 20 further explore the Transformation Pathways from a regional perspective. Chapter 21 synthesizes the work of these chapters and assesses how to accelerate the required transformations.

11.2 Two narratives of transformation

The two narratives are individually coherent stories rooted in the general assumptions for each Transformation Pathway, as defined in Section 9.4 and presented in **Boxes 11.1** and **11.2**. The two pathways differ mainly in terms of the focus on behaviour versus technology solutions:

- The *Behaviour-focused* transformation describes a world in which society transforms its core values towards sufficiency, placing less emphasis on material consumption and status, and reducing the pressure on natural systems.
- The *Technology-focused* transformation describes a highly globalized and market-driven world that relies primarily on technological development and efficiency gains in both supply and demand to overcome the global environmental crises.

Both pathways move beyond gross domestic product (GDP) as a measure of well-being, instead focusing more on the well-being of nature and society (Jansen et al. 2024). It is important to stress that the pathways are not mutually exclusive, as technology improvements and consumption changes are parts of both scenarios (Mosca et al. 2024; Strefler et al. 2024), but each pathway relies on them to differing extents. Analysing such archetypal pathways together provides a broader understanding of possible solutions and of the associated synergies and trade-offs. In reality, elements of both pathways can already be found in different contexts, as discussed in Chapter 9.

11.2.1 Solutions presented by each pathway

Each narrative combines coherent strategies and solutions across five systems – economy and finance, energy, food, materials/waste, and environment – to achieve internationally agreed goals (**Table 9.1**). They were constructed at the solution level within the Goal, Solution, Lever framework introduced in Chapter 13 (13.6). As a result, the narratives provide sufficient detail to support the scenario quantification process, while maintaining consistency with Chapters 14–18.

The definition of the adopted solutions for each system was based on an analysis of similar scenario exercises conducted recently (Kok et al. 2023; Soergel et al. 2024; Strefler et al. 2024; van Heerden et al. 2024) and refined by an internal consultation with expert authors from the GEO-7 Systems and Regional chapters (9.4). Alternative solutions in each pathway reflect key debates about sustainability and intend to foster discussion at multiple levels (Aguiar et al. 2020). The food and environment systems are entangled via land use and practices, and their solutions relate to the land-sparing and land-sharing and the Half-Earth approaches (Bennett 2017; Ellis and Mehrabi 2019), as well as the debate on agricultural practices and intensification (Struik et al. 2014; Tittonell 2014; Duru et al. 2015; Newell and Taylor 2018). As the *Behaviour-focused* transformation pathway assumes deeper value changes, it explores a paradigm shift towards land-sharing, in which no clear separation exists between humans and nature (Pereira et al. 2020). For this pathway, shared-use protected areas cover 50 per cent of the world, moving away from the contested Half-Earth proposal of fully protected areas for conservation (Büscher et al. 2016; Büscher and Fletcher 2020). There is also a focus on ecological intensification, with an increase in agroecological or biodiversity-based practices (Tittonell 2014; Duru et al. 2015).

The *Technology-focused* pathway follows the current dominant sustainability paradigm of efficiency and profit, exploring the land-sparing solution (Phalan et al. 2011) that assumes a clear division between human uses and natural areas. It envisions a highly concentrated spatial model for food production, achieved through developing more efficient and less harmful agricultural practices. This approach aims to promote large-scale sustainable agricultural production on a reduced area (Cassman and Grassini 2020).

The food system transformation in each pathway also diverges in relation to future diets, particularly in relation to protein sources, to mitigate the impacts of cattle ranching (Godfray et al. 2018). While the *Behaviour-focused* pathway prioritizes a shift towards plant-based diets, following the EAT Lancet report (Willett et al. 2019), the *Technology-focused* pathway explores a partial substitution with cultured meat (Chen et al. 2022; Cassman and Grassini 2025; Hocquette et al. 2025).

Likewise, comparable differences apply to the energy system. A key distinction between the pathways relates to the degree of energy production centralization (Burke and Stephens 2018; Fuss et al. 2018; Waller et al. 2020). The *Technology-focused* pathway assumes centralized production and distribution, while in the Behaviour-focused pathway, it is mostly decentralized. The pathways have different configurations in relation

Box 11.1 The Behaviour-focused Transformation Narrative

Behaviour-focused transformation pathway

In the Behaviour-focused transformation, goals are achieved through lifestyle, behavioural and value changes. It envisions a future where increased societal awareness of global environmental crises drives a shift toward a sufficiency worldview. This transformation is guided by principles of sharing, reciprocity, responsibility and care, local-to-global outlooks, and aiming to reconcile human well-being with ecosystem health. Multiple forms of knowledge are combined, including mainstream science and Indigenous and Local Communities (ILC)'s philosophies, practices and values. Examples include climate change adaptation measures, regeneration of abandoned lands, and governing fisheries and rivers. Aligned with these general assumptions, coherent solutions are adopted for each system:

Economic systems:
Beyond economic growth and GDP as a measure of well-being. Reduction of externalities through a combination of pricing and non-pricing instruments. Investments in technological and social solutions oriented towards enabling human and nature wellbeing.

Environmental systems:
Guided by principles of land sharing, there is an increase in symbiotic/sustainable use of protected areas (terrestrial, freshwater, marine), aiming for 50% of the world in 2050. Natural regrowth/restoration on abandoned agricultural lands due to changes in the food system provides carbon removal service.

Energy systems:
Behavioural and lifestyle changes lead to reductions in energy demand in rich regions, while middle-and lower-income gain access to basic energy services. Emergence of "prosumers" facilitated through small-scale decentralized electricity generation. Micro-grids, demand-side management, and distributed storage are scaled up.

Food systems:
Shift from input-based to biodiversity-based practices, use of mixed systems, and Indigenous and local knowledge in production. Rainwater management increases yields on rainfed cropland. Waste reduction by community-based food production and distribution. There is a strong shift to plant-based foods, particularly amongst populations with over consumption of meat produced unsustainably. Lower demand for industrial and processed foods, with an emphasis on recovering traditional foodways.

Circularity:
Reduced material footprints by avoiding conspicuous consumption and a digitally supported sharing economy. Reusing, repairing, refurbishing, recycling of products and materials becomes the norm. Informal circularity networks are fostered by providing access to infrastructure and training. Unsustainable and harmful components and products are replaced by more environmentally friendly, humane and sustainable alternatives.

Box 11.2 The Technology-focused Transformation Narrative

Technology-focused transformation pathway

In the Technology-focused transformation, the goals are achieved through innovation and technological solutions. It envisions a future characterized by an urbanized world with significant global trade and technological spill-over and leapfrogging, in which society relies on price-mediated and technological solutions together with expert and scientific knowledge:

Environmental systems:
Guided by the principle of sparing, biodiversity hotspots are protected, and the efficient use of non-protected areas allowing the regeneration of large areas of natural vegetation. Natural vegetation covering more than 30% is pursued together with significant afforestation via planted forests.

Economic systems:
Reduction of externalities through pricing mechanisms and efficiency gains. High investments in technical solutions to environmental and social problems, while valuing multiple ecosystem services and human capabilities as a metric of well-being.

Energy systems:
Supply-side investments with a focus on efficiency, clean energy, interconnectivity, and high levels of electrification. The electricity system is built around centralized distribution networks, large-scale supply and storage of electricity, and large-scale grid interconnections. Technological solutions, including power-to-liquids, advanced biofuels, hydrogen, and carbon capture and storage are made mainstream.

Food systems:
Aligned to the land-sparing principle, i.e., producing more in less area, freeing land for nature restoration, biodiversity protection, and conservation. Adoption of efficient irrigation, automated agricultural production, and the substitution of animal products by novel foods such as cultured meat. Technical means are adopted to tackle food waste and losses.

Circularity:
Design driven by cradle-to-cradle concerns, increased efficiency, and reduced waste. Monitoring, reviewing, and redesigning of products and implementation of necessary infrastructure, improves recyclability and enables high recycling rates. Efficient modular design in buildings and goods reduces their material footprint and increases their longevity and ability to be refurbished. Technological solutions including machine learning contribute to waste management and circular supply chains.

to the energy matrix, including the use of contested technologies such as nuclear plants and bioenergy (Fuss et al. 2018; Waller et al. 2020). Concerning energy demand, the *Technology-focused* pathway prioritizes efficiency, while the *Behaviour-focused* pathway limits energy demand via lifestyle changes.

For the materials/waste system, the Transformation Pathways reflect the sharing and circular economy debate (Henry et al. 2021). The main difference is that the *Behaviour-focused* pathway relies on a sharing economy (Curtis and Lehner 2019) combined with decreased consumption, while the *Technology-focused* pathway relies on the efficient design of products and reduced waste. The two pathways involve different levels of reuse, repairing, refurbishing and recycling. Finally, in the case of the economic and finance system, the difference is in the importance of regulatory or market instruments to reduce environmental externalities.

In the solutions for the *Behaviour-focused* pathway, a basic assumption is that integrating sources of knowledge results in a type of co-creation. A widely-recognized example of such co-creation, where Indigenous Knowledge informs conventional approaches, supports biodiversity preservation through the use of fire knowledge in the Amazon region, Australia, and other parts of the world (**Box 3.2**) (Burrows, Burbidge and Fuller 2004; Mistry, Bilbao and Berardi 2016; Hoffman et al. 2021; Ruscalleda-Alvarez et al. 2023). Other examples include implementing climate change adaptation measures such as climate risk communication and green infrastructure (Petzold et al. 2020); regenerating abandoned land in the Amazon with medicinal and food species (Levis et al. 2018); and governing fisheries and restoring rivers in the European Arctic (Brattland and Mustonen 2018; Ogar, Pecl and Mustonen 2020).

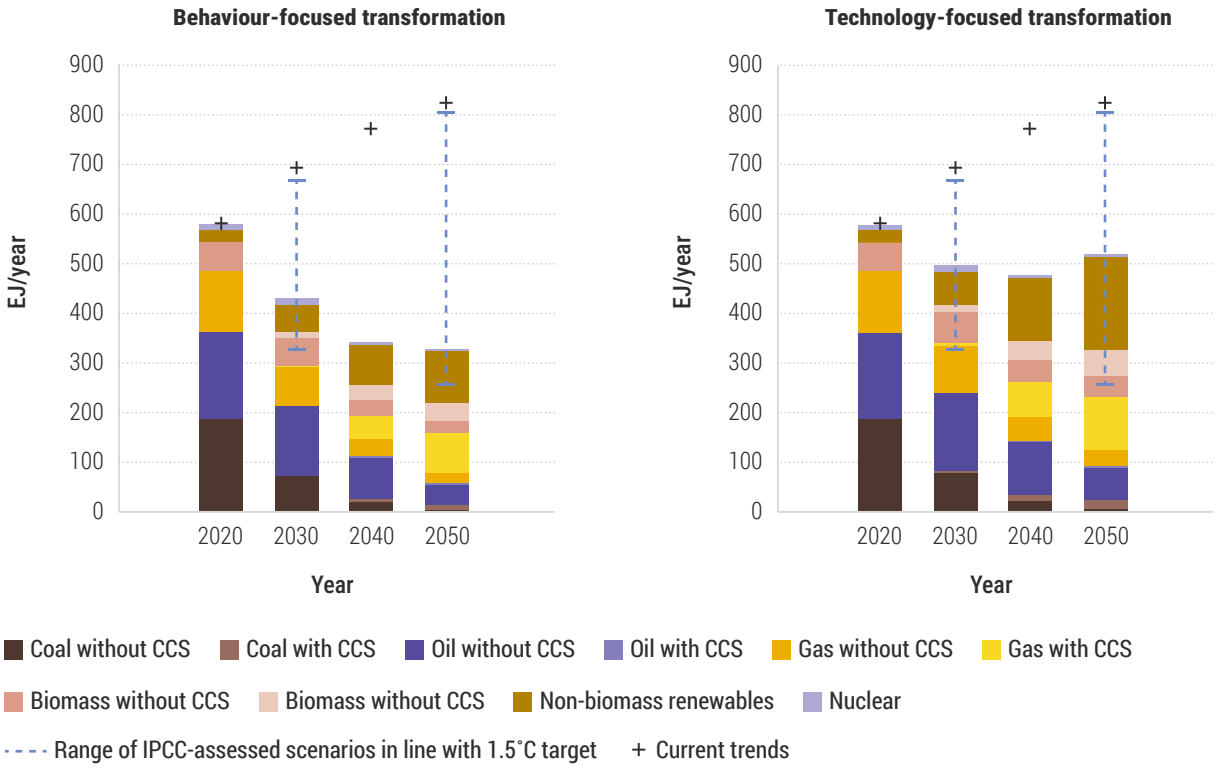
11.2.2 Quantification of the narratives

The first step for building model-based projections of the Transformation Pathways consists of translating the qualitative narratives into appropriate parameterization for the model framework described in Section 9.5. The table in Appendix 11.1 presents an overview of how the narratives were translated into quantitative parameters for the models. The Appendix also maps the broad strategies outlined in

Credit: biletskiy/Envato

the narratives to the solutions presented in the section describing the solution pathways for each system in Chapters 14–18.

The quantitative results of the target-seeking scenarios are compared to the *Current Trends* scenario detailed in Chapters 9 and 10 using the same activity and population drivers as the middle of the road scenario of the Shared Socioeconomic Pathways (SSP2) (O'Neil et al. 2017). However, our scenarios differ from each other in the technological and behavioural assumptions as outlined in the boxes. This comparison helps highlight the different transformations each system may undergo to bring them in line with the goals detailed in **Table 9.1**.



11.3 Systems transformations

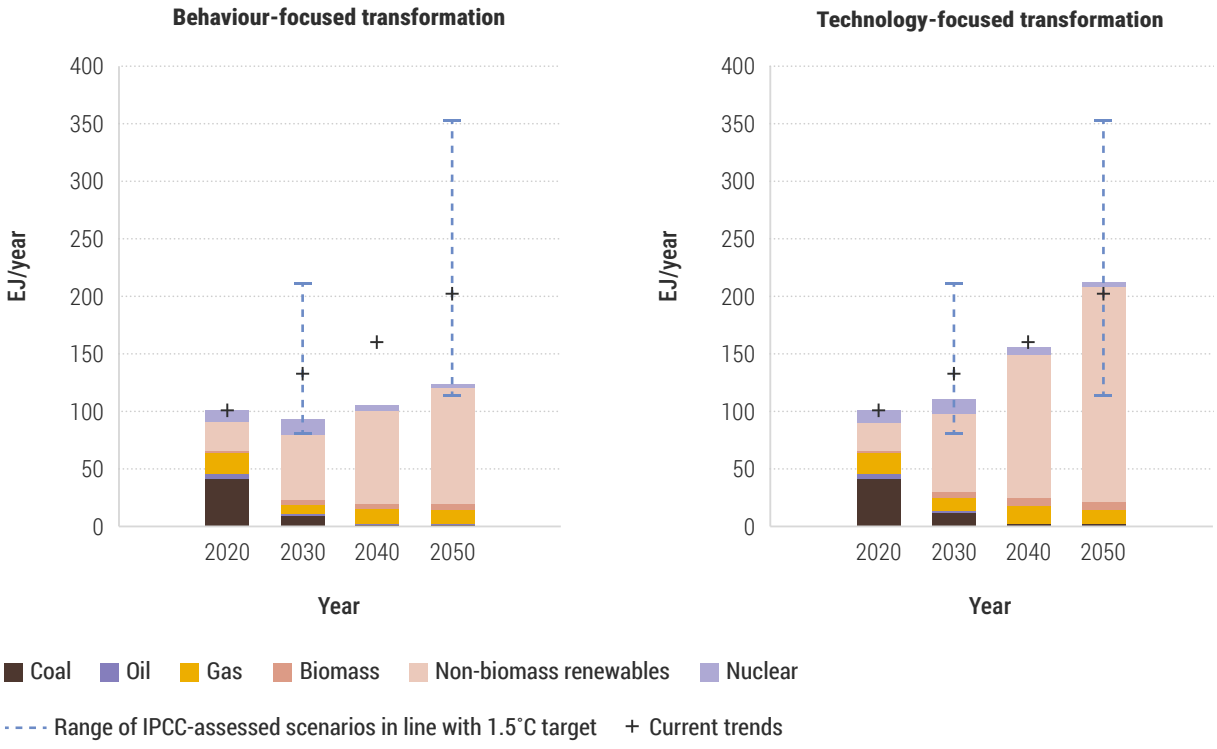
The following sections describe the transformation each system undergoes to make it consistent with the goals set out in Section 9.3. Contrasting the results of the two pathways illustrates that there are multiple routes towards achieving these goals, each with their associated system transformations, challenges and opportunities.

11.3.1 Energy

Both pathways show a clear break from the *Current Trends* scenario concerning energy supply and demand. **Figure 11.1** shows a decrease in the short term, arising from the use of energy-efficient technologies in both supply and demand as in the *Technology-focused* pathway, and in structural changes and reduced demand for energy services in the *Behaviour-focused* pathway. By 2050, both pathways show lower energy demand than today while also meeting energy access goals and lowering primary energy demand compared to the *Current Trends*, by 40 per cent and 60 per cent for the *Behaviour-focused* and *Technology-focused* pathways, respectively. These projections may differ across different regions based on their socioeconomic situation, with Chapters 19 and 20 providing further details.

Figure 11.1: Primary energy disaggregated across energy resources for the *Behaviour-focused* and *Technology-focused* transformation pathways

Note: The range of the results from the IPCC-assessed scenarios as shown in dashed lines are in line with the 1.5°C target (>50 per cent probability, with no or low overshoot, immediate action after 2020). The scenarios from the IPCC-AR6 have a primary focus on climate change goals only. CCS refers to Carbon Capture and Storage.



Source: IMAGE 3.3 Model (transformation pathways) and AIM Model (current trends)

As highlighted in **Table 9.1**, both Transformation Pathways are consistent with the goals of the Paris Agreement, as well as goals concerning access to clean energy (11.4.1; 11.5.1). This implies an immediate and rapid reduction in the extraction and use of fossil resources, with total fossil fuel consumption in 2050 at less than 50 per cent of 2020 and most of the remaining fossil fuel emissions addressed by Carbon Capture and Storage (CCS). Remaining fossil fuel use is focused on sectors that are particularly difficult to completely decarbonize by 2050, such as heavy industry and transport (Edelenbosch et al. 2024). Bioenergy also contributes to decarbonizing these sectors and contributing to climate goals (11.4.1), especially forms of transport that cannot be electrified. Approximately two-thirds of the bioenergy supply is projected to come from agricultural and forestry residues, reducing the need for extra agricultural land (11.3.2).

The use of zero-carbon energy options needs to increase rapidly, building upon and beyond the recent growth in these energy resources, with an annual growth rate of around 8–11 per cent from 2020 to 2030. Zero-carbon energy resources play an obvious role in the power generation sector, where renewable energy is projected to constitute more than 85 per cent of electricity production by 2050, increasing from approximately 25 per cent in 2020 (**Figure 11.2**). Nuclear power is projected to play a smaller role due to its high costs compared to renewables.

This decarbonization of power generation is crucial since both Transformation Pathways highlight the importance of increased electrification. In 2020, electricity constituted approximately 20 per cent of total final energy use. In the *Current Trends* scenario, this increases to approximately 26 per cent by 2050, and the Transformation Pathways both show an important shift, with electrification rates more than doubling to up to 45 per cent. Despite this vast increase in the share of final energy supplied by electricity, due to the described changes in total energy demand, total electricity production is projected to be lower than the *Current Trends* scenario. This highlights that a lower overall demand for energy makes it easier and less

Figure 11.2: Electricity generation disaggregated across primary energy sources for the *Behaviour-focused* and *Technology-focused* transformation pathways

Note: The range of results from the IPCC-assessed scenarios as shown in dashed lines are in line with the 1.5°C target (>50 per cent probability, with no or low overshoot, immediate action after 2020). The scenarios from the IPCC-AR6 have a primary focus on climate change goals only.

Source: IMAGE 3.3 (transformation pathways) and AIM (current trends)

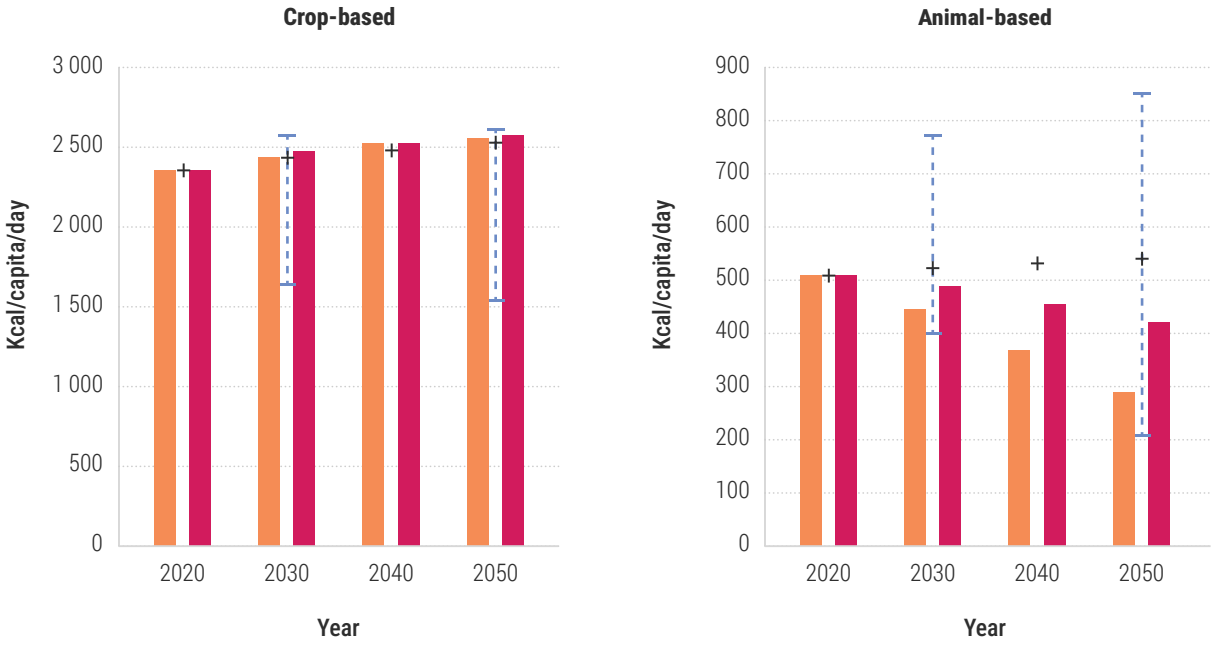
costly to scale up the required infrastructure for an effective decarbonization of the electricity supply and the overall energy system (11.6).

The Transformation Pathways indicate that recent technological progress leading to lower costs for renewables compared to fossil-fuel power generation could strongly support the transition (Way et al. 2022). However, the Transformation Pathways also highlight that the high rates of electrification will require expanding electricity generation, driven by the growth in zero-carbon generation capacity (van Heerden et al. 2024), and ensuring universal, reliable and just access through the expansion of interconnected electricity networks. This requires policy frameworks to support positive effects for all populations, including Indigenous Peoples and diverse local communities (Hoicka, Savic and Campney 2021; Vega-Araújo and Heffron 2022; Owen et al. 2023) (16.2.1).

Development and distribution of keystone technologies that also enable behavioural and lifestyle choices for a reduction in energy demand – and associated infrastructure – is vital (Sugiyama et al. 2024). Examples include demand-side management; efficiency-improving technologies in the built environment, including heat pumps and rooftop photovoltaics; and provision of reliable electrified public transport. Others are increased efficiency in energy conversion and use, energy storage options enabling high penetration of intermittent renewable energy, and the development of advanced fuels and energy carriers to decarbonize hard-to-abate sectors. Further details on options and important actors for transforming the energy system are discussed in Chapter 16.

It is noteworthy that more than 50 per cent of minerals necessary for the energy transition are situated adjacent to or within Indigenous Peoples' lands and rural communities (Owen et al. 2023), highlighting the importance of ensuring a just and equitable energy transition. In this context, centring Indigenous perspectives concerning the relational connection among humans, other beings and lands can help to create effective, ethical and sustainable polices to achieve energy goals (Sankaran and McIntyre-Mills 2022; Kennedy et al. 2023; Loginova et al. 2025).

11.3.2 Food



The global food system is responsible for approximately one-third of greenhouse gas (GHG) emissions (Crippa et al. 2021), drives land degradation through the expansion of agriculture that also leads to biodiversity loss and causes pollution through fertilizer use and large-scale livestock production (4.3, 17.2.5). The *Current Trends* scenario presented in Chapter 10 shows that further exacerbation of these issues is expected. Both selected Transformation Pathways present changes that put the food system on a different track.

Ensuring adequate nutrition for a growing population leads to modest continued increases in food demand in both Transformation Pathways, but a strong reduction in the consumption of livestock-based products (**Figure 11.3**). In the *Technology-focused* transformation, meat substitutes replace traditional meat. In the Behaviour-focused transformation, the overconsumption of animal products is reduced most notably in high- and middle-income regions due to higher awareness of the health and environmental consequences, in line with the EAT-Lancet diet (Willett et al. 2019).

Figure 11.4 highlights that in both the Transformation Pathways, livestock production decreases substantially due to dietary shifts, as also shown by Springmann et al. (2018) and Kozicka et al. (2023). This transformation also delivers a substantial decrease in feed requirements, from both grazing and crop harvests – resulting in lower demand for crop production. Furthermore, any increase in crop production is mitigated by reductions in food waste, with high-tech solutions and community-based solutions driving the transformations in the *Technology-focused* and the *Behaviour-focused* pathways, respectively. However, relative increases in crop production are also accounted for: cultured meat itself requires substantial amounts of crop as feedstock, while the transition to healthy, plant-based diets results in strong production increases in protein-rich crops, such as legumes, as well as fruits and vegetables. Accounting for all these dynamics, compared to the *Current Trends*, the *Behaviour-focused* pathway shows a modest decrease while the *Technology-focused* pathway shows a modest increase in total crop production.

Technological developments, including widespread automation of farm practices and genetic improvements of crop varieties, lead to strong yield and livestock efficiency increases in the *Technology-focused* pathway, where cereal yields are about 30 per cent higher in 2050 compared to today (**Figure 11.5**). In the *Behaviour-*

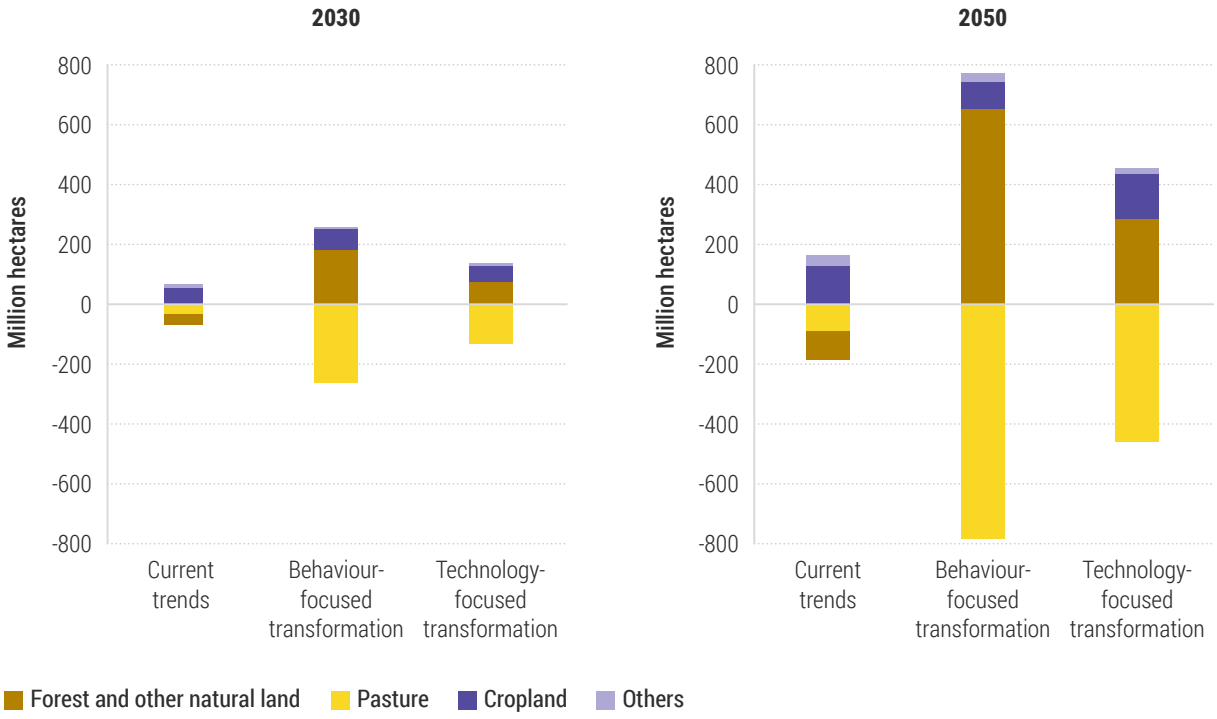
Source: IMAGE 3.3 (transformation pathways) and AIM (current trends

focused pathway, nature-focused practices, including mixed cropping and integrated systems, are assumed to become dominant. Improved land management allows for continued yield improvement, albeit at a lower level than the other pathways as there is less focus on agricultural intensification.

Mixed cropping and integrated systems could be aligned with the diversity of Indigenous food systems (Baena et al. 2023), with implications for new policies that recognize and protect the foods typically consumed by Indigenous communities, but which are still considered neglected plants (Baldermann et al. 2016; Melash et al. 2023) or wild foods (Carvalho et al. 2015; Kenny et al. 2018). The prioritization of Indigenous food systems and diets could also reduce the introduction of ultraprocessed foods into Indigenous territories, which Indigenous Peoples and scientists have identified as harmful for health, livelihoods and cultures (Kuhnlein and Receveur 1996; Kuhnlein et al. 2006).

These developments have massive implications for land use (**Figure 11.6**). In the *Behaviour-focused* pathway, the reduction in livestock production results in major decreases in grazing land, up to 780 Mha – half of total cropland area today – from 2020 to 2050. This allows for large increases in natural land, contributing to the achievement of climate, land degradation and biodiversity goals (11.4.1; 11.4.3; 11.4.4). Cropland continues to increase in all cases to achieve the food access goal, but also partly due to increased demand for bioenergy (11.3.1). However, a focus on residue-based bioenergy means that cropland requirements do not surpass 80 Mha or 5 per cent of projected cropland.



11.3.3 Material resources

Materials are crucial for meeting multiple goals, including energy system transformation, adequate housing and mobility, among other services. All pathways show a short-term increase in material demand, however innovation and technological change bring it back to current levels by 2050 on the *Technology-focused* pathway, while behavioural change can lead to reductions in global material demand of over 20 per cent by 2050, compared to 2020 (**Figure 11.7**). Global material demand is projected to peak at around 115 billion tons by 2030 for both *Transformation Pathways*, with the *Current Trends* increasing beyond 160 billion tons by 2050. This also translates into per capita material savings globally, reducing to 11.1 tons per capita on the *Technology-focused* pathway and 8.6 tons per capita on the *Behaviour-focused* pathway by 2050 from 17.6 tons per capita in the Current Trends. However, it is important to note that there are significant differences across regions and socioeconomic groups (Chapters 19 and 20).

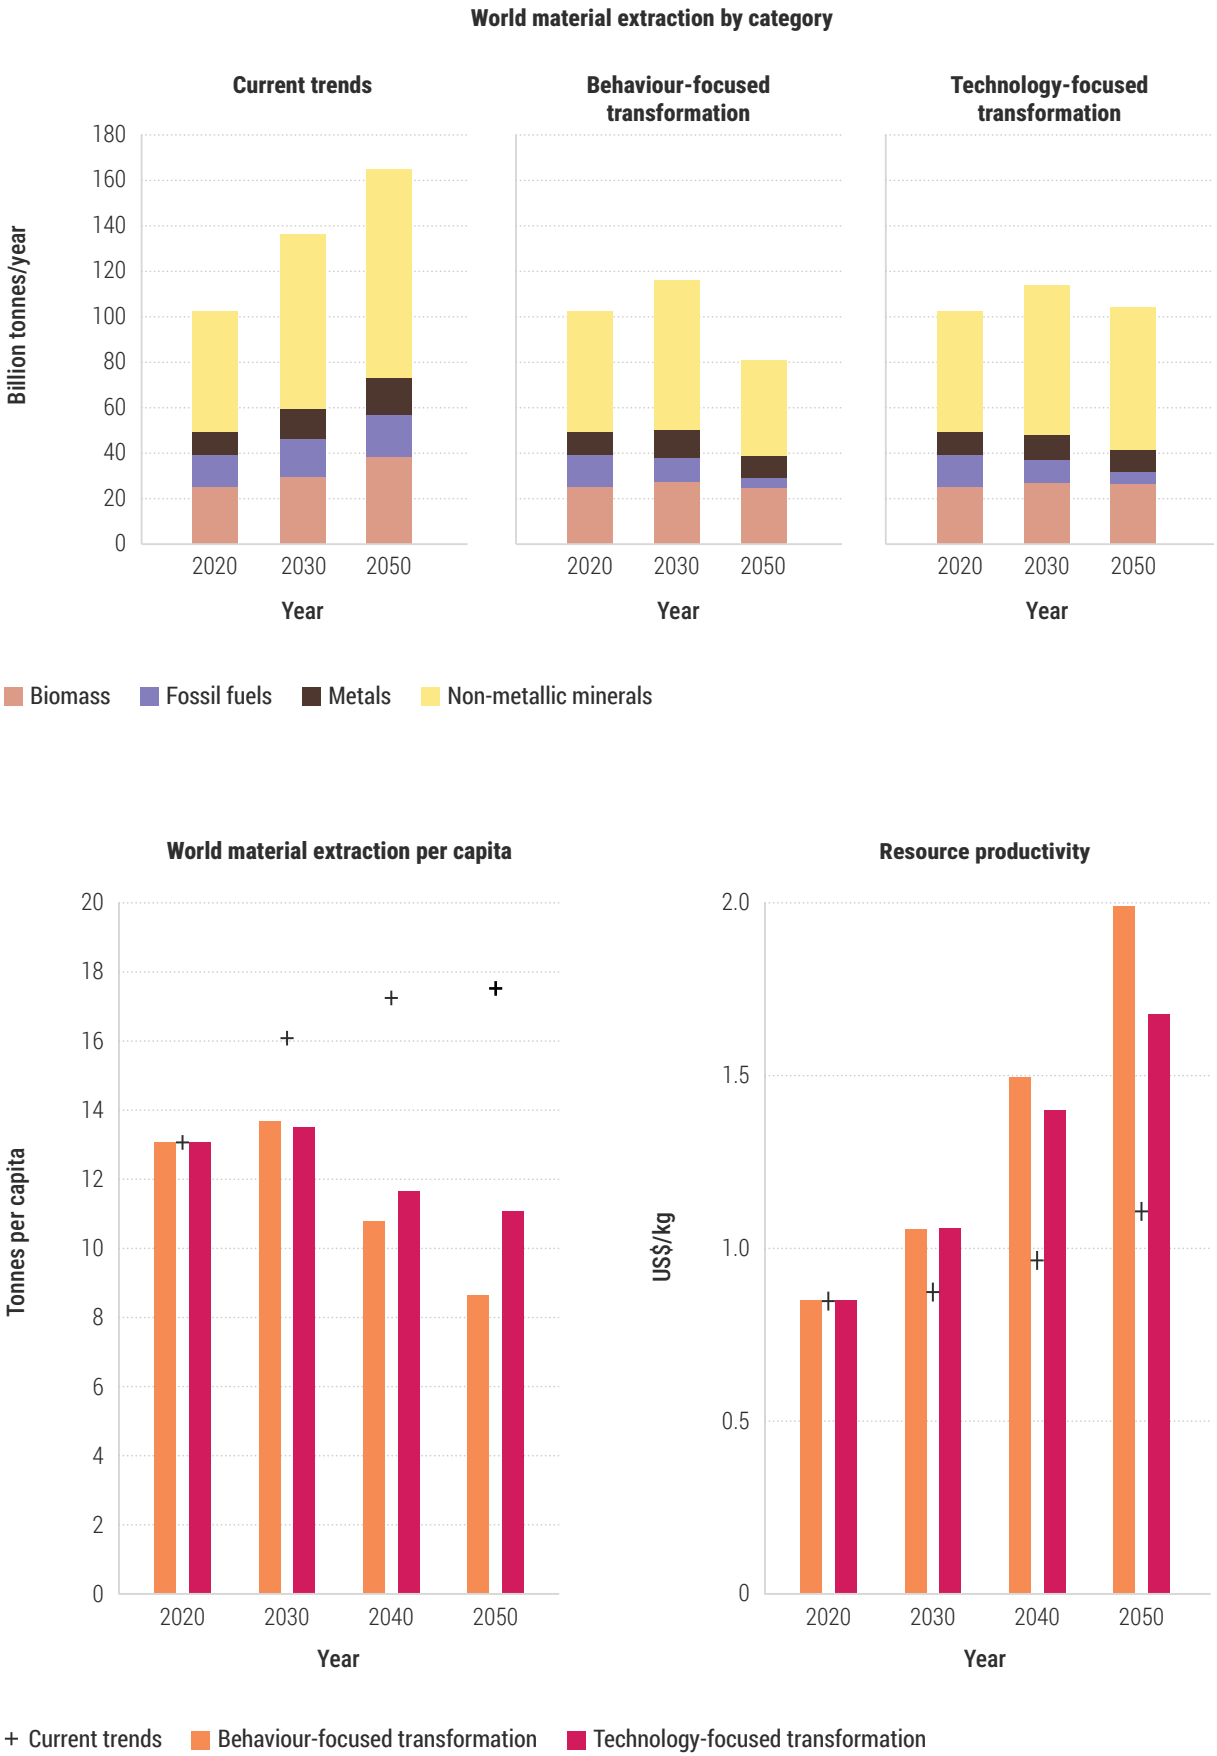
These results align with the Global Resource Outlook 2024, which conducts a similar analysis with a specific focus on resource use (United Nations Environment Programme 2024). However, the Transformation Pathways presented here demonstrate a more radical shift in material supply and demand systems and recycling rates, leading to lower material intensities than the Global Resource Outlook.

Under both Transformation Pathways, fossil fuel extraction reduces by more than 70 per cent by 2050, showing the highest reduction in material demand relative to the *Current Trends*. The reduction in the Technology-focused pathway is driven by technological change and the *Behaviour-focused* pathway benefits from changes in energy consumption patterns, as

Figure 11.6: Changes, compared to 2020, in land areaby land-use classification in 2030 and 2050

Source: IMAGE 3.3 model (transformation pathways), AIM model (current trends).

described in Section 11.3.1. The second largest percentage reduction, minus 40 per cent, is related to metal extraction, driven by the resource efficiency policies from both the demand side and the supply side. However, for certain metals such as copper, there is still increasing demand until 2050 due to its importance for energy transformation. In the *Behaviour-focused* pathway, the percentage reduction of non-metallic minerals, minus 54 per cent, highlights the importance of behavioural change in housing patterns, reflected by lower floorspace demand compared to the *Current Trends*. These reductions in material demand help reduce environmental damage and pollution arising from mining and transporting bulk materials.



11.3.4 Environment

To achieve the twin goals of reversing biodiversity loss and halting land degradation, both Transformation

Source: GTEM

Pathways diverge strongly from the *Current Trends*, which entail continued conversion of natural land and intensification of agricultural production (10.3; 10.4). The required transition in environmental management includes expanding protected areas, increasing restoration of degraded ecosystems, sustainable land and sea use, reforestation and rewilding, and improved agricultural land management.

Protection of natural lands is common for both Transformation Pathways. In the *Technology-focused* pathway, 30 per cent of all terrestrial land is protected, in line with the Kunming-Montreal Global Biodiversity Framework (**Figure 11.8**). In addition, forests with high carbon stocks are protected in Annex II countries under the Reducing Emissions from Deforestation and Forest Degradation (REDD+) framework. In the *Behaviour-focused* pathway, an even more ambitious protected-area effort is introduced where 50 per cent of all terrestrial land has its natural capital protected (Wilson 2016; Kok et al. 2023), explicitly assuming that all ecosystems are considered equally valuable. Small-scale land use is allowed in these areas in line with the mutually beneficial use of nature, including agroforestry and other integrated production systems. In both pathways, natural peatlands are strictly protected. Total protected areas increase from approximately 2100 Mha in 2020, to 5500 and 6900 Mha in 2050 in the *Technology-focused* and *Behaviour-focused* pathway, respectively.

Furthermore, former agricultural lands and degraded forest areas undergo restoration, showing an increase in forest area (**Figure 11.6**). In the *Technology-focused* pathway, this is mainly achieved through reforestation and afforestation with monocultures, leading to relatively fast growth and carbon uptake. In the *Behaviour-focused* pathway, forests and other vegetation types are restored through natural regeneration providing slower carbon uptake, with some rapid-growth afforestation in high-income regions allowed to provide adequate carbon storage for the climate targets (11.4.1). Indigenous Knowledge and practices can provide guidance in ecosystem restoration, including cosmogonies and traditions that recognize all ecosystem elements as

Figure 11.8: Protected areas in the technology-focused transformation pathway

Note: The values indicate the percentage fraction of each grid-cell that is protected from conversion to human use. Each grid-cell is 30 arc-minute or approximately 50 km by 50 km at the equator. The colours indicate the primary reason for protection, distinguishing between biodiversity (green), carbon storage (orange), peatland (purple) or both biodiversity and carbon storage (blue). Protection of a given location may lead to synergies across biodiversity and carbon storage

alive, making regeneration an integral part of life (IK & LK Dialogues 2025).

Improved land management is an important part of the required transition since in all pathways, agricultural production continues to use large areas. In the Behaviour-focused pathway, small-scale measures proliferate; by 2050, 50 per cent of all agricultural land would be under improved management, with a 40 per cent increase in residues left on the field and measures in place to store rainwater for the dry season. In the Technology-focused pathway, high-tech solutions include the expansion of irrigated areas, with a simultaneous increase in irrigation efficiency through the widespread implementation of drip irrigation to limit overall water consumption (11.4.6).

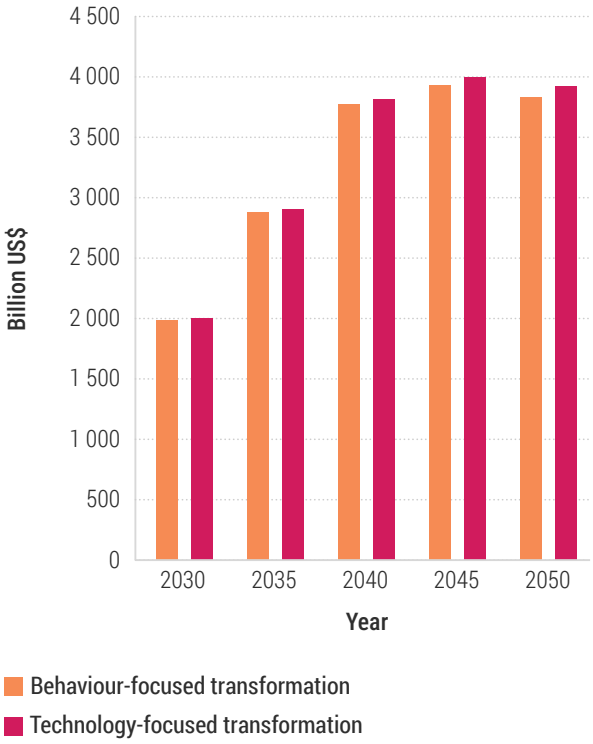
11.3.5 Economy and finance system

The Transformation Pathways require rapid changes both in the demand and supply of goods and services, with important implications for economic growth, and different financing needs. The deployment of required technologies necessitates accelerated technical progress, capacity expansion and extension and upgrade of energy and transport infrastructure (11.3.1), and sufficient financial resources to support investment growth. From the demand side, changes in behaviour towards environmentally sound lifestyles and circular patterns of consumption (11.3.1; 11.3.2; 11.3.3) are also required, which in many cases come at a low cost or even with gains for the households and firms adopting them.

The economic and financial effects of the transformation are also dependent on the relevant choice of instruments. Carbon pricing is a key instrument for carbon neutrality, as it internalizes the damages from climate change into the decisions of households, firms and governments, leading to emissions reductions. It can also generate revenues to finance clean energy innovation and research and development, support low-income households and reduce labour costs to firms through reduction of social security contributions.

The projected carbon prices consistent with the *Transformation Pathways* range from US$ 200–400/tCO_2 in 2050, with **Figure 11.9** showing the resultant revenues. The *Technology-focused* pathway requires higher carbon prices than the *Behaviour-focused* pathway to meet the climate goal due to increased demand for energy and land use, but it also has slightly higher carbon revenues that can aid with investments in technologies. It should be noted that these carbon prices do not reflect the potential costs of achieving technological innovations or behavioural changes, which are assumed a priori in the pathways. The economic and financial systems are affected by opposing forces in both Transformation Pathways. **Table 11.1** presents the main channels through which the economy and finance systems are affected. The possible role of different policy levers and different

actors in the transformation of the financial system is further explored in Chapter 14.



11.4 Environmental implications

This section discusses the effects of the transformation of the five systems on the global environmental crises. It also explores both the positive and negative implications of issues that are not directly included, including water stress and freshwater pollution.

11.4.1 Greenhouse gas emissions and climate change

In the two Transformation Pathways, CO_2 emissions decline immediately and rapidly, reaching net zero around mid-century, with total GHG emissions following a similar pattern (**Figure 11.10**). Other major GHGs, particularly CH_4 and N_2O, are also significantly reduced, but do not reach net zero. Thus, both *Transformation Pathways* present a complete break with the *Current Trends*.

Figure 11.9: Revenues from carbon pricing, used to accelerate R&D and support low-income households

Source: GEM-E3 model

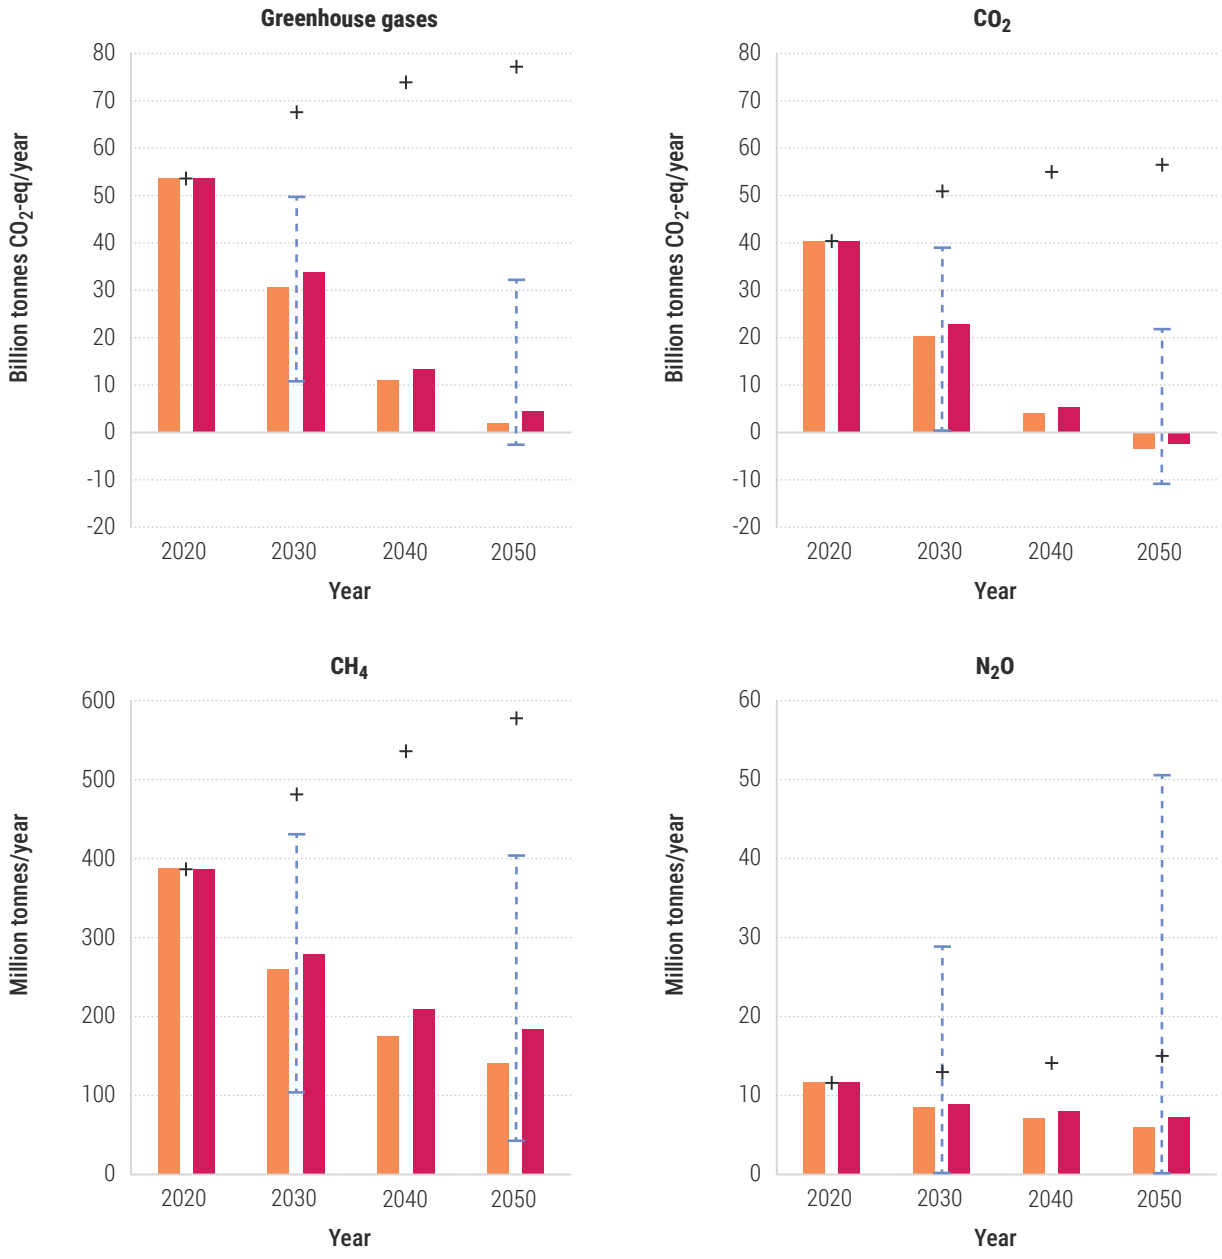


Table 11.1: Decomposition of GDP impact on key factors per Transformation pathway compared to the current trends

Factor	Behaviour-focused transformation pathway	Technology-focused transformation pathway
Technical progress for clean technologies	(-) Moderate impact on technology progress as most substitutions are driven by behavioural changes	(+) Accelerated technological progress, enhanced diffusion, lower capital costs
Finance	(+) No significant requirements for financing/ freeing up capital/lowering interest rates	(+) Lower capital costs due to technical progress, lower financing needs and stress on capital markets (-) Significant dependence on technology and capital/different costs of capital per country and technology/stress on capital markets
Resource availability	(+) Climate change mitigation lowers the cost of climate inaction (10.6.5) (+) Productivity infrastructure (+) Improved health and working hours	
Skills	Neutral impact on skills	(+) High-skilled labour, higher wages and income (-) Human capital availability potentially a barrier as it may not be available in time to support the rapid transformation required

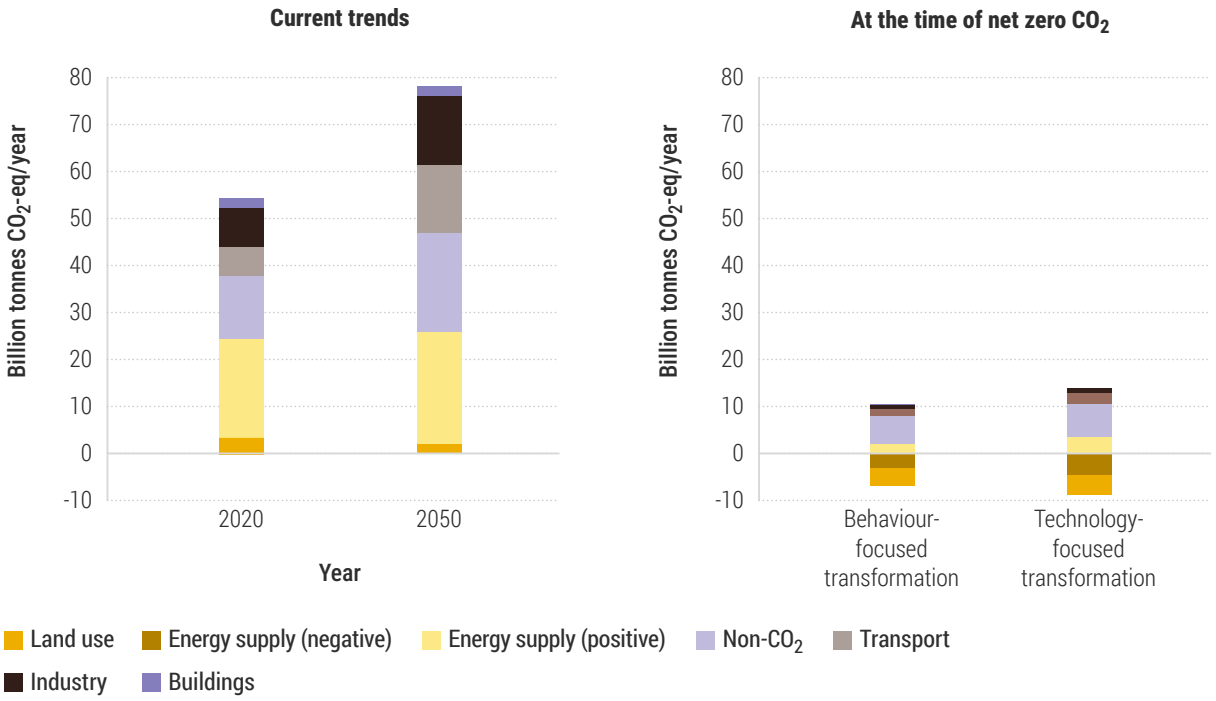
Note: decomposition of GDP effect on key factors per Transformation Pathway compared to the Current Trends, which shows an average annual global GDP growth of approximately 3 per cent in the period 2020–2050. A (+) sign signifies a positive impact on GDP, and the (-) sign signifies a negative impact on GDP.

While the emission trajectories of the two Transformation Pathways are very similar, as they both reach the same climate goal, they do highlight the different possible routes. Besides the large differences in the energy, land use and materials/waste systems described in Sections 11.3.1 to 11.3.4, there are important differences regarding the sectoral emissions and when net-zero CO_2 is reached (**Figure 11.11**). Looking at the *Current Trends*, while overall emissions in 2050 are higher, the relative contribution of different sectors is similar compared to 2020. The *Behaviour-focused* pathway shows a very rapid emission reduction in the energy demand and supply sectors, with remaining positive emissions at

Figure 11.10: Global emissions of greenhouse gases, CO_2, CH_4 and N_2O

Note: All panels show the current trends and the two transformation pathways. The range of the results from the IPCC-assessed scenarios as shown in dashed lines are in line with the 1.5°C target (>50 per cent probability, with no or low overshoot, immediate action after 2020). The scenarios from the IPCC-AR6 have a primary focus on climate change goals only

Source: IMAGE 3.3 (transformation pathways) and AIM (current trends)



the time of net zero mostly made of non-CO_2 gases and hard-to-abate emissions in heavy transport and power production. The *Technology-focused* pathway shows a slightly higher aggregate level of positive emissions, requiring more negative emissions using CO_2 removal measures to compensate for remaining emissions from hard-to-abate sectors (Edelenbosch et al. 2024).

Carbon dioxide removal (CDR) options such as afforestation, bioenergy with carbon capture and storage or direct air capture of atmospheric carbon, and carbon capture and storage in general, can help with meeting strict climate targets (Pathak et al. 2022). These technologies play three important roles in meeting the climate targets (Babiker et al. 2022). They contribute to rapid reduction in overall emissions by decarbonizing the energy system; CDR can counterbalance residual emissions from hard-to-abate sectors (**Figure 11.11**); and CDR technologies can ensure climate goals are met after potential overshoot by providing net-negative emissions. Meeting targets on climate change without the use of CDR is extremely difficult, as it would imply reducing all GHG emissions to zero within a very tight time frame.

While both Transformation Pathways rely on CDR, the level of net-negative emissions is higher in the case of *Technology-focused*, increasing further towards the end of the century. This higher dependence of on CDR is due to the *Technology-focused* pathway permitting increased use and rapid adoption of these advanced technologies. The *Behaviour-focused* pathway reduces this dependency, lowering the need for carbon removal by having lower energy and land-use demand (11.3.1; 11.3.2).

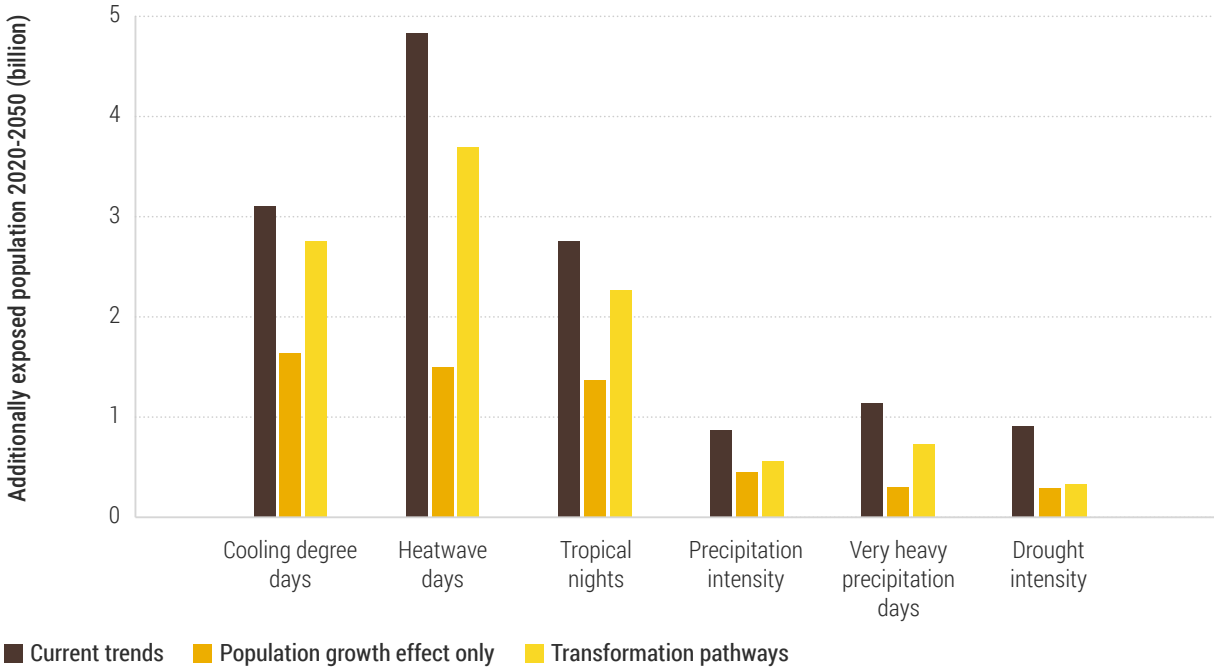
Dependence on CDR poses risks for land-use competition, if it leads to upscaling of crop-based bioenergy with carbon capture and storage (BECCS) as well as land-based mitigation in the form of rapid-growth afforestation. The *Behaviour-focused* pathway poses a lower risk, with a 30 per cent and 50 per cent lower need for CDR in 2050 and 2100, respectively, compared to the *Technology-focused*. Both pathways aim to minimize the use of crop-based bioenergy by prioritizing bioenergy supply from agricultural and forestry residues (11.3.1). Concerning land-based mitigation, the *Behaviour-focused* pathway has a bias towards natural regrowth on abandoned lands that tend to have a slower uptake of CO_2, rather than

Figure 11.11: Sectoral GHG emissions in the year 2050 under the current trends, and at the respective year of net zero CO_2 for the two transformation pathways, compared to 2020 emissions

Note: For Transport, Industry and Buildings, only emissions from combustion are shown. Indirect emissions are covered under Energy supply.

Source: IMAGE 3.3 model (transformation pathways) and AIM model (current trends)

active use of the land for carbon management. The Technology-focused pathway focuses on planted forests that have a rapid uptake of CO_2 but may pose risks for biodiversity and land management. Notably, direct air carbon capture and storage is projected to become cost-competitive only after 2050, significantly later than other CDR methods.



The *Transformation Pathways* present a vastly improved situation compared to the *Current Trends* concerning climate impacts by tracking six climate impact indicators: cooling degree days, heatwave days, tropical nights, precipitation intensity, very heavy precipitation days and drought intensity (**Figure 11.12**). By 2050, global population exposures across the six indicators are projected to increase compared to 2020 levels. Temperature-based indicators show the most substantial increases, with the Transformation Pathways presenting a marked reduction compared to the *Current Trends*. Hydrological indicators also show increases in exposure, although this is less pronounced than in the temperature-based ones, with the Transformation Pathways again presenting the best outcomes. For both the precipitation-intensity and drought-intensity indices, the Transformation Pathways significantly mitigate climate impacts, nearly bringing the exposure levels down to what would be expected from population growth alone. This highlights the potential of the Transformation Pathways to completely mitigate certain climate change impacts.

Overall, the Transformation Pathways reduce population exposure to climate risks compared to the *Current Trends* by 200 million to 1 billion people, depending on the indicator. Importantly, while the Transformation Pathways significantly reduce exposure across indicators compared to *Current Trends*, they do not eliminate increased exposure entirely. This illustrates the importance of adopting adaptation measures in parallel.

11.4.2 Air pollution

The ambient air quality projections are shown in **Figure 11.13**, with both Transformation Pathways depicting comparable ambient air pollutant concentration trends. The average global $PM_{2.5}$ decreases by 25 per cent

Figure 11.12: Additional population exposed to climate impacts in 2050

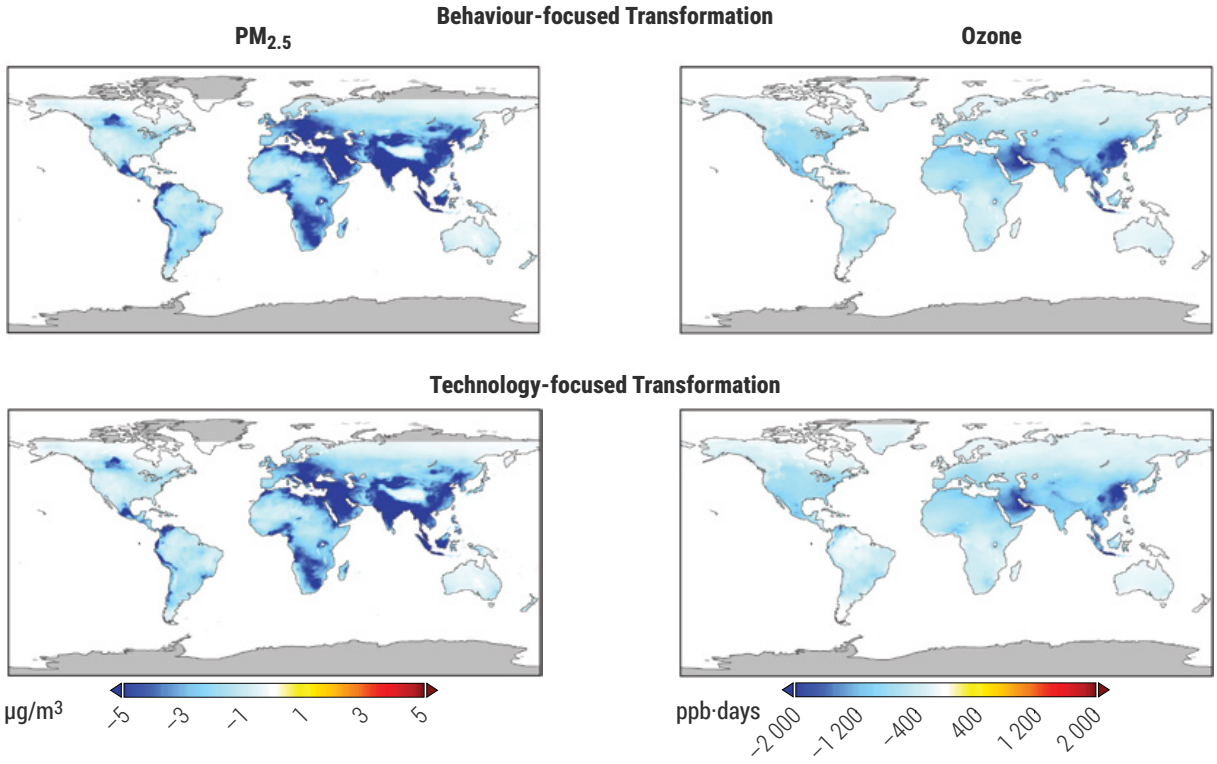
Note: Bars show additional population exposure levels relative to 2020 (see Figure 10.7 for 2020 levels), due to population growth, and further exposure under both the current trends warming (2.2°C by 2050) and the transformation pathways warming (1.55°C) for six climate indicators. Both Transformation pathways have identical climate outcomes, dictated by the goals of the Paris Agreement.

Source: RIME Model

between 2020 and 2050, with most of the decrease happening in the short term. Both Transformation Pathways represent an improvement compared with the *Current Trends* pathway where concentrations increase between 2020 and 2030 (10.4.2). This improvement is mainly due to the abatement of SO_2 with minus 80 per cent and NOx with minus 70 per cent emissions in the energy and transport sectors, as well as NH_3 with a reduction of 40 per cent in the agricultural sector. The reduction in $PM_{2.5}$ is higher than other published scenarios with similar climate targets (Turnock et al. 2020), indicating the added benefits of transforming multiple systems simultaneously. Global ozone levels fall by 8 per cent in 2050 compared with 2020, due to the combined effect of NOx and VOC emissions abatement. Such concentration reduction is comparable with the one projected for the same time window in a scenario exploring maximum feasible reduction (Bessagnet et al. 2024).

Both transformations show an improvement in global population exposure to $PM_{2.5}$ compared to the *Current Trends* pathway, mainly observed in Eastern and Southern Asia, Eastern Europe and Africa, while comparable or slightly lower levels are observed in the rest of the world (**Figure 11.14**). Global ozone summer exposure is lower in the Transformation Pathways compared to the Current Trends everywhere, with the maximum improvements of minus 1000–2000 ppb·day in the Persian Gulf and Eastern Asia, due to changes in fossil fuel production and use.

These differences result in decreased mortality due to air quality (**Figure 11.15**). Between 2030 and 2040, almost 1.2 million premature deaths per year are prevented due to lower $PM_{2.5}$ exposure. Both Transformation Pathways show that by 2050 the prevented premature deaths reduce to 0.9 million as the *Current Trends* pathway also shows a benefit in the longer term, reducing the overall positive impact of the Transformation Pathways. A similar situation is observed in the mortality attributable to ozone exposure, with a maximum benefit of 220,000 prevented premature deaths annually in 2040.



These results are in line with those reported in the literature for a scenario with similar climate targets (Yue et al. 2024). However, while the air pollution

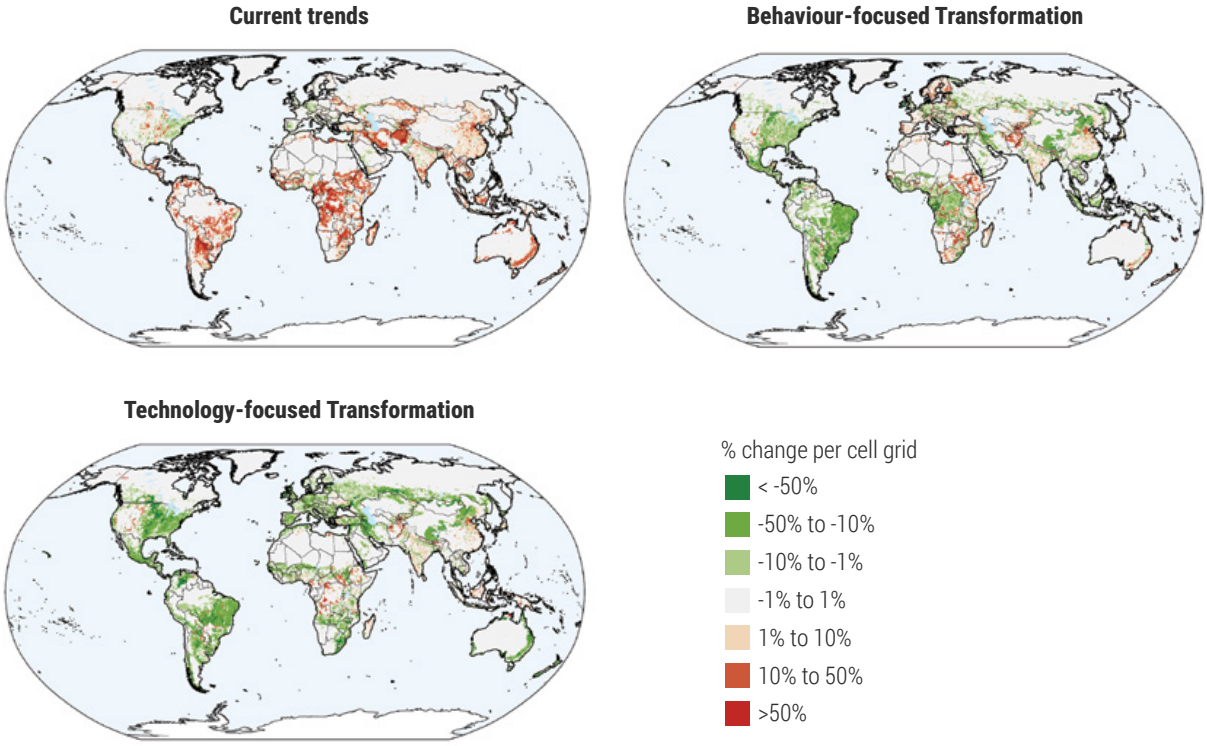
Figure 11.15: Prevented premature deaths from air pollution in transformation pathways compared to current trends

Source: JRC-FASST model

goal of reducing population exposed to $PM_{2.5}$ to less than 10 per cent by 2050 is met for most regions, it is not achieved in Africa with 47 per cent by 2050, nor Asia and the Pacific with 39 per cent by 2050. This is despite improvement compared to both 2020 and the *Current Trends* pathway and highlights the difficulties in achieving this goal in these regions.

11.4.3 Land degradation



In both Transformation Pathways, the continued loss of natural land observed in *Current Trends* is mostly prevented, largely due to reductions in grazing land driven by dietary shifts (**Figure 11.16**). This allows for a large-scale expansion of forests and other natural land. In the near term of 2025–2030, Sub-Saharan Africa still experiences some land-use change for food production, but the extent varies across the pathways. As the *Technology-focused* pathway includes strict protection of all forests with high carbon stocks, conversion mostly takes place in non-forest ecosystems such as the Savannah. In the *Behaviour-focused* pathway, synergistic use of forest and non-forest ecosystems implies some conversion of natural land to food production in Sub-Saharan Africa.

Both Transformation Pathways preserve substantially more carbon stocks in above-ground vegetation compared to the *Current Trends* (**Figure 11.17**). Forest expansion also allows for additional sequestration of carbon, with faster uptake in the *Technology-focused* pathway due to large-scale planting of managed forests. Soil carbon stocks are also affected by different agricultural management methods. Most notably in the *Behaviour-focused* pathway, the use of residues on fields fosters soil organic carbon levels, increasing by 2.9 tons carbon per hectare (tC/ha) on average from 2020 to 2050.

11.4.4 Biodiversity loss

Figure 11.18 breaks down the characteristics of the Transformation Pathways leading to improved biodiversity outcomes, highlighting the very important role of climate change mitigation and the land-use changes outlined in Sections 11.4.1 and 11.4.3. Limiting

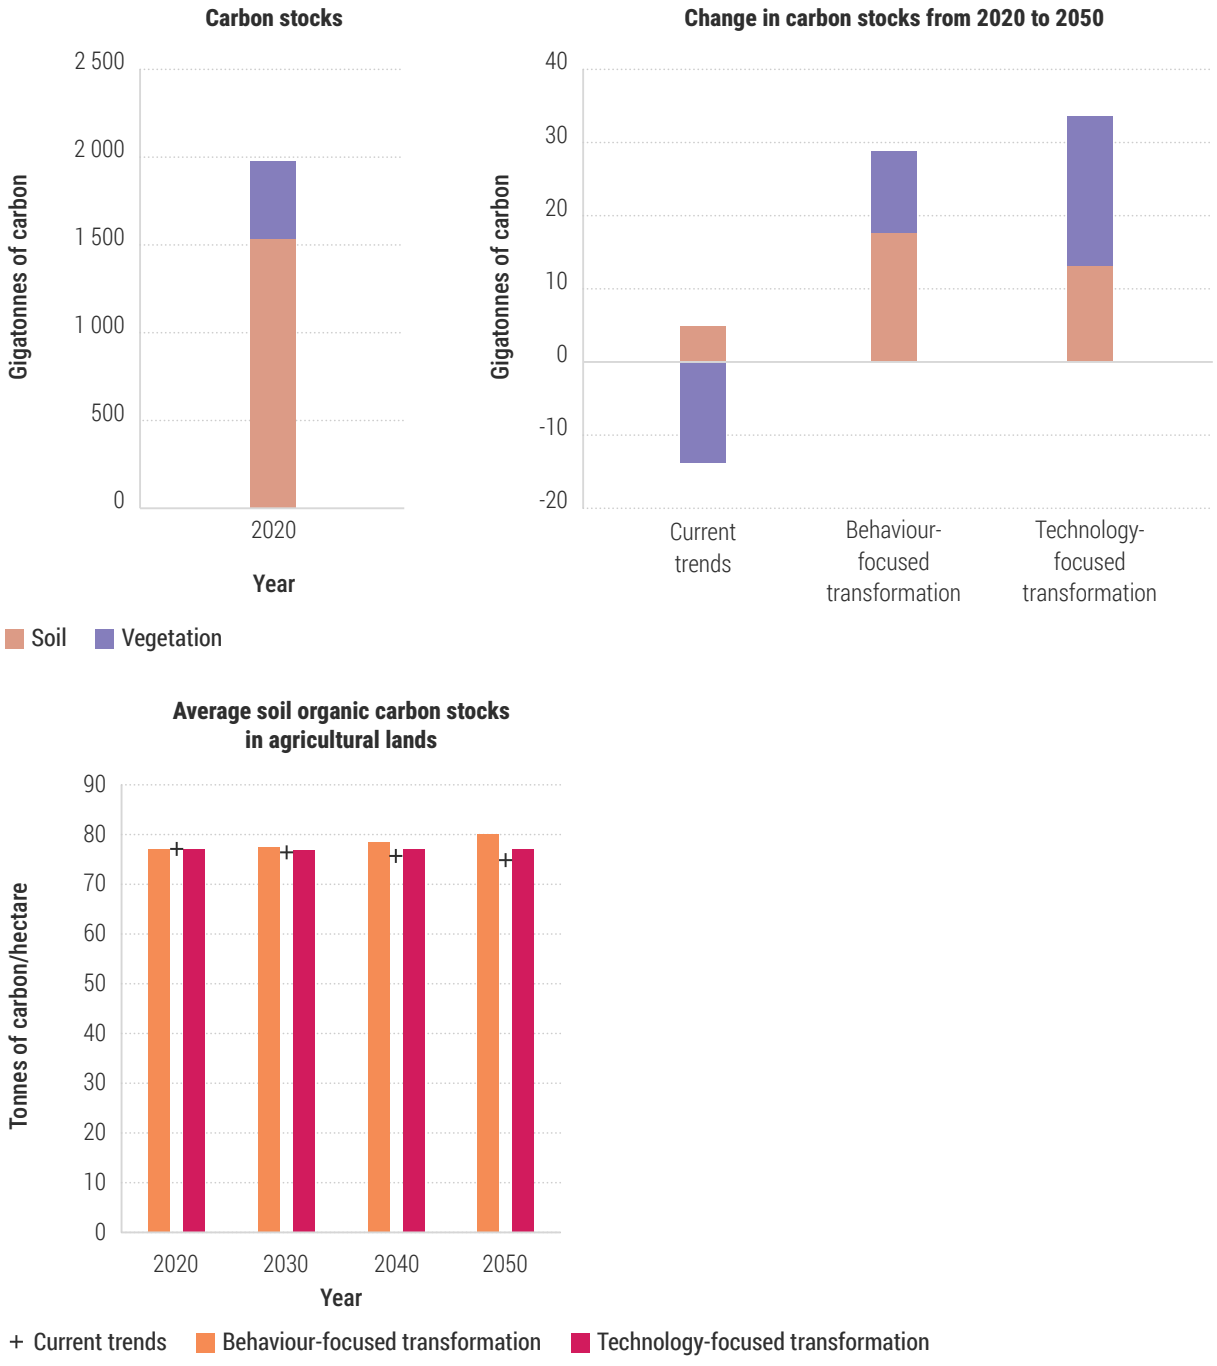


Figure 11.16: Natural land conversion in the Current Trends, Technology-focused and Behaviour-focused Transformation Pathways from 2020 to 2050

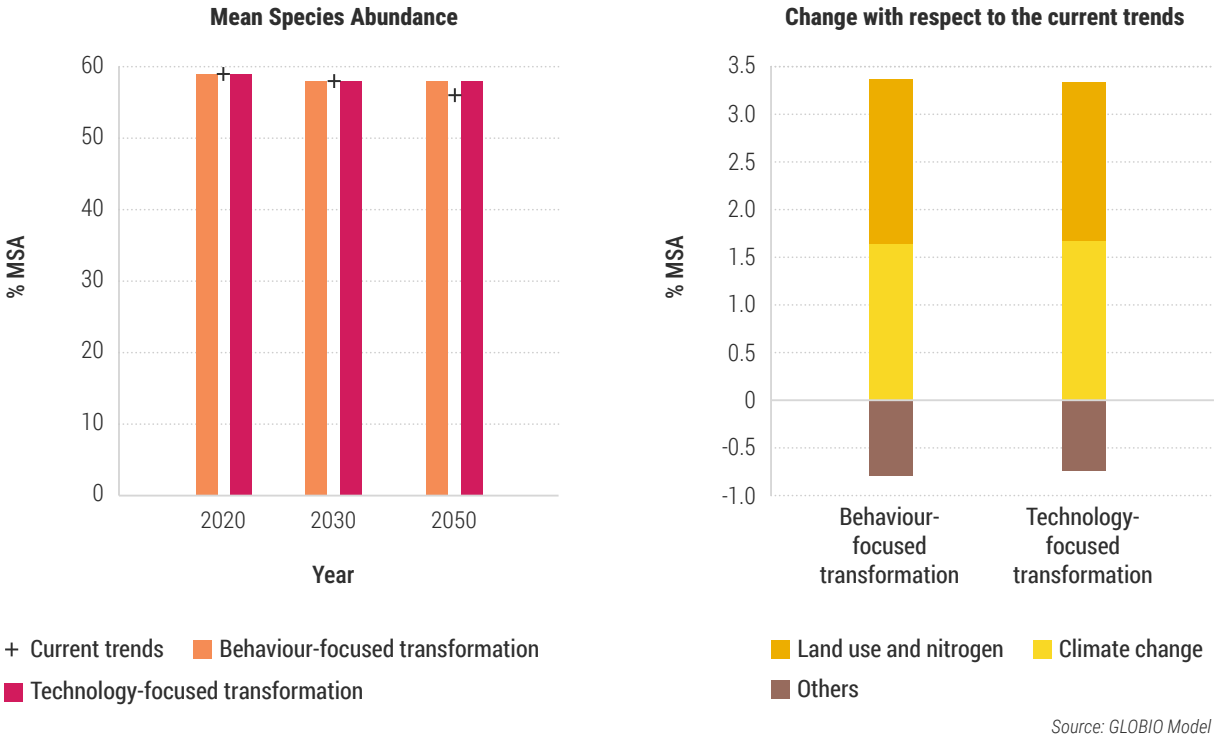
Note: An increase (red colour) indicates deforestation or use of other natural land, while a decrease (green colour) indicates reforestation or restoration of other natural ecosystems

Source: IMAGE 3.3

Figure 11.17: Carbon stocks in soils and vegetation in 2020, and changes in total soil and vegetation carbon stocks from 2020 to 2050



Source: IMAGE 3.3 model

global mean temperature increase to 1.5°C improves mean species abundance, a measure of biodiversity intactness, by more than 1.6 per cent. Differences in land-use projections and nutrient pollution lead to a further improvement of 1–2 per cent, depending on the Transformation Pathway.

The different transformations of the energy and food systems contribute to improving biodiversity compared to the Current Trends via their implications for climate change and land use. In both Transformation Pathways, while cropland increases slightly, reductions in pastureland result in improved biodiversity outcomes. The impacts of climate change increase slightly up to 2050, but less so than the Current Trends, stabilizing biodiversity loss. This highlights that mitigating climate change, while avoiding additional land use, is important in achieving biodiversity targets.

Figure 11.18: Projections of Mean Species Abundance (MSA), and factors contributing the MSA difference in the transformation pathways with respect to the current trends in 2050

Source: GLOBIO Model

Halting biodiversity loss also requires addressing other factors, including introducing biodiversity-friendly forestry (Kok et al. 2018); reducing direct harvest from ecosystems, including hunting and collection of plant products at unsustainable levels, whether legal or illegal; reducing pollution and reducing habitat fragmentation. However, although these transformations are an important prerequisite, they need to be supplemented by appropriate land protection and conservation measures. Indigenous Peoples' practices and their knowledge related to food production and regeneration are vital to consider

Credit: thananit_s/Envato

in addressing the impacts of these transformations on biodiversity (Argumedo et al. 2021; FAO, Alliance of Bioversity International and CIAT 2021). The implications of the Transformation Pathways for global biodiversity are comparable to other studies (Kok et al. 2023; Leclère et al. 2020), which include a similar set of measures as those employed in the Transformation Pathways, albeit at different levels and combinations.

11.4.5 Nutrient pollution

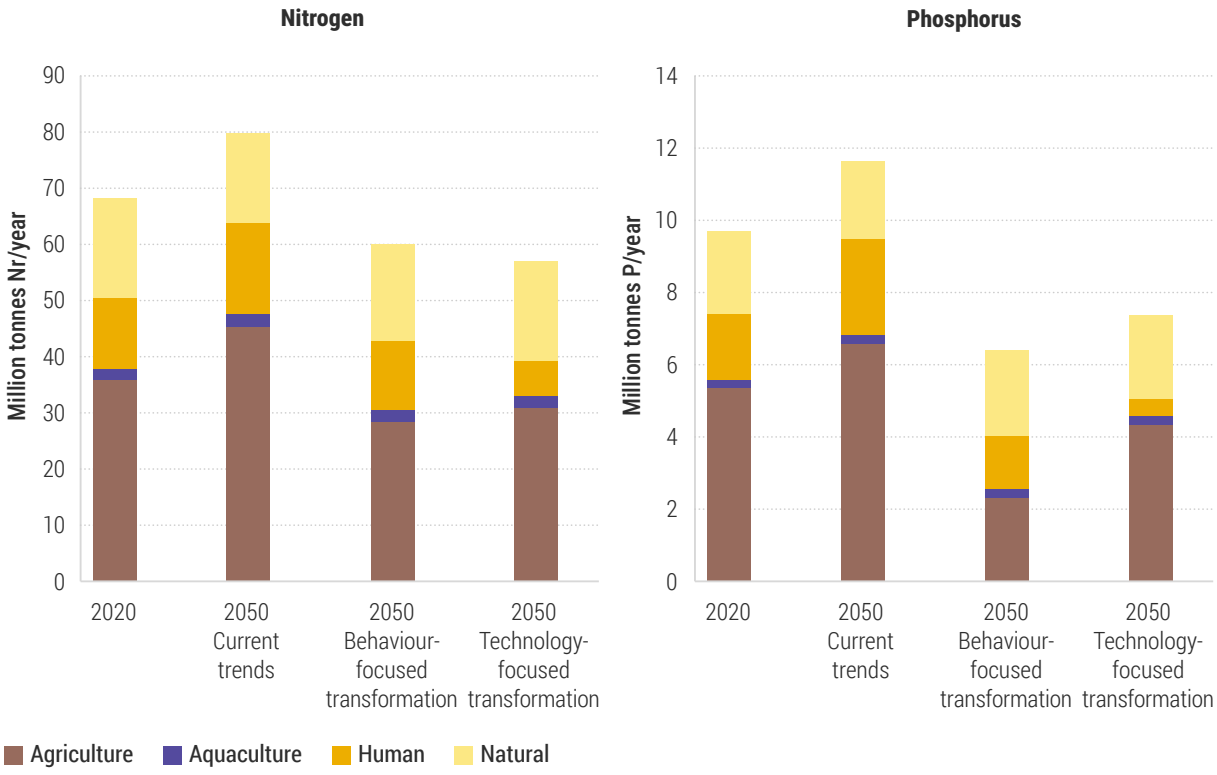
In both Transformation Pathways, water quality improves through lower nitrogen and phosphorus concentration levels. The key driver for this is increased nitrogen-use efficiency in agriculture, implying a lower fertilizer input to produce the same amount of crops, and lower losses to the environment. Additionally, dietary changes mean less livestock, which reduces manure production, thereby limiting nutrient release into surface waters (**Figure 11.19**). Wastewater from human activities also affects water quality, particularly the degree of sanitation and wastewater treatment (van Puijenbroek et al. 2023). Substantial improvements in wastewater treatment in both Transformation Pathways are assumed, reducing the effects of wastewater on surface water quality. Finally, high levels of nutrient production can also lead to the acidification of soils, degradation of coastal ecosystems and eutrophication, with associated impacts on biodiversity (Guo et al. 2010; Zhu et al. 2018; Zhu et al. 2020; Norwegian Meteorological Institute 2024). All these impacts are mitigated in the Transformation Pathways by reducing the discharge of nutrients.

To assess improvements in water quality, the areas exceeding threshold concentration values for surface and groundwater are compared (10.4.5). **Figure 11.20** shows that surpassing the threshold for both nitrogen and phosphorous in surface and groundwater is projected to be substantially lower in the Transformation Pathways when compared to both the Current Trends pathway and 2020 values. These improvements are focused on high-income regions. In middle- and low-income regions, water quality improvements are more difficult to achieve due to strong increases in population, consumption and agricultural production.

11.4.6 Water scarcity

As shown in **Figure 11.21**, both Transformation Pathways project lower water use than the Current Trends. Interestingly, in the Technology-focused pathway, the Sahel region of Sub-Saharan Africa shows an increase in water use compared to Current Trends due to efforts to increase agricultural production through irrigation. This highlights a potential trade-off between water scarcity and agricultural production, even with efficient irrigation. In contrast, the Behaviour-focused pathway focuses more on increasing rain-fed yields with small-scale decentralized improvements to save rainwater, and applying mulch to prevent evaporative losses and increase infiltration (Jägermeyr et al. 2017; He and Rosa 2023). Furthermore, decarbonizing the energy system is also beneficial due to less water demand from thermal power plants, which have very high cooling water needs.

While both pathways show a decrease in blue water consumption compared to the Current Trends, in the Technology-focused pathway, this is driven by increased irrigation efficiency, whereas the Behaviour-focused pathway benefits from fewer irrigated areas. The Behaviour-focused pathway sees a strong increase in green water consumption through better rainwater management. This highlights the different ways in which both pathways increase their water productivity and decrease total cropland compared to the Current Trends. Especially in the Behaviour-focused pathway, the rainwater management options applied in small-scale agriculture contribute to a large decrease in the water yield gaps on rain-fed cropland (**Figure 11.22**).



11.5 Socioeconomic implications

Environmental and social systems are intimately connected. This section focuses on the implications of the Transformation Pathways on socioeconomic outcomes and human well-being, mainly at a broad, global level. However, meeting the included targets requires addressing disparities across regions and populations, including addressing gender-specific needs and the effects of environmental crises (Pirzadeh et al. 2023).

11.5.1 Basic material needs

The Transformation Pathways assume the ability to meet basic human material needs, including hunger, as well as access to key infrastructure like electricity, water, and sanitation (9.3). Both Transformation Pathways lift almost 200 million people out of

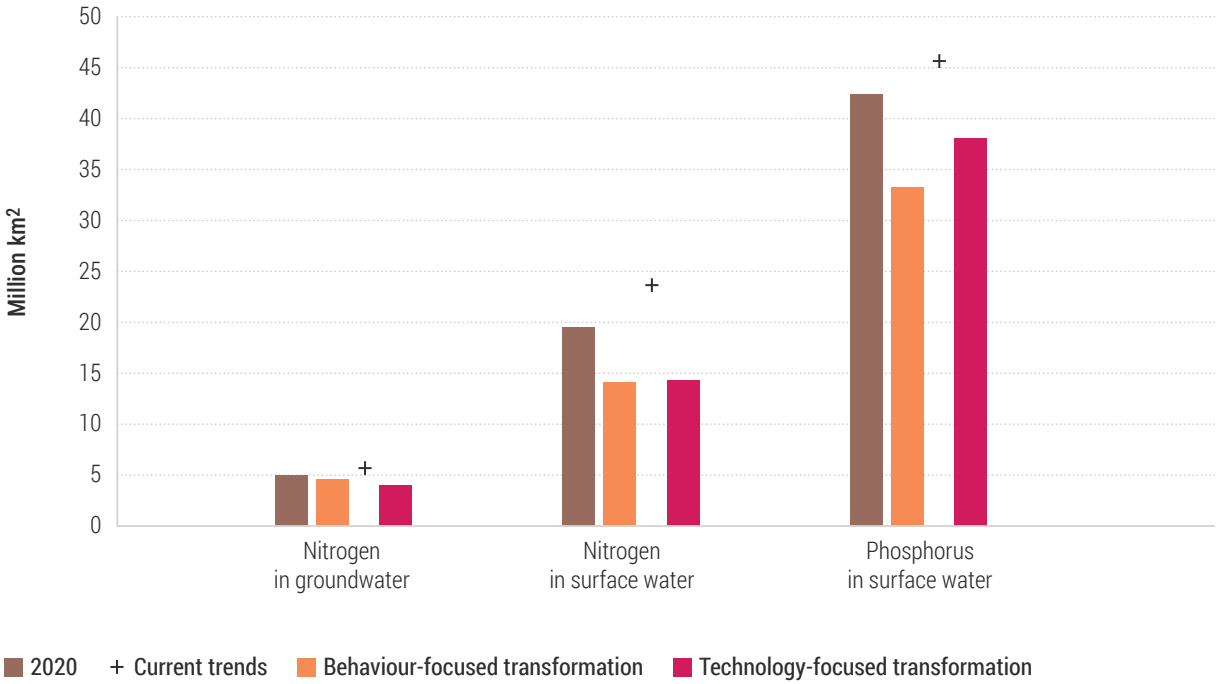


Figure 11.19: Delivery of nitrogen and phosphorus to surface water from the different sources for 2020 and 2050

Note: Nr refers to reactive nitrogen.

Figure 11.22: Changes in total rainfed cropland extent, and the rainfed cropland that is experiencing a water yield gap of over 30 per cent and 50 per cent

Source: IMAGE-LPJml Model

undernourishment, relative to the Current Trends pathway, by 2050 (**Figure 11.23**). In the Technology-focused pathway this is achieved via technologically assisted yield improvements and boosted incomes from economic growth (11.3.2; 11.5.5). In the Behaviour-focused pathway, improved agricultural management, food distribution and shifting dietary patterns are the main drivers of food security.

The described changes in agricultural production contribute to alleviating hunger, but they cannot solve the problem of food access. Addressing physical and economic barriers and facilitating improved access and affordability, through food prices and nutrition education for example, is critical in both Transformation Pathways (Drewnowski et al. 2020; Kasprzak et al. 2021). To achieve the undernutrition target in the Transformation Pathways, the

Figure 11.23: Trend in selected SDG targets

Source: IFs model

distribution of calories globally needs to match the food distribution equality of countries performing above the 90th percentile (Verhagen et al. 2023). This points towards the requirement of additional calorie distribution measures (Aziz et al. 2021; Fabian, Gomez and Rosete 2023). Furthermore, an inclusive nutrition education needs to recognize Indigenous Knowledge about local diets, acknowledge food preferences and make information about new types of foods universally accessible.

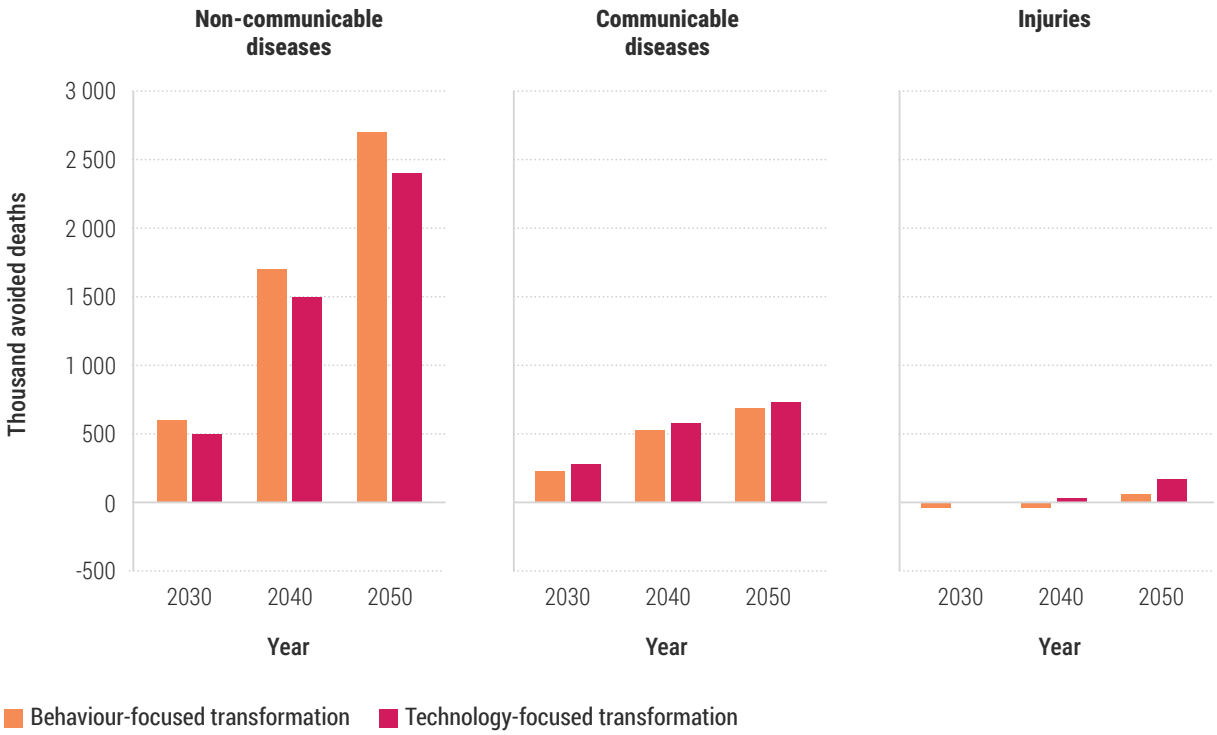
Universal access to electricity results in nearly 120 million electricity connections by 2050, beyond what is projected in the Current Trends scenario. Most of these additional connections would be in rural areas where electricity may be limited and building new connections can be costly (Mitra and Buluswar 2015; Dagnachew et al. 2017; Perez-Arriaga et al. 2019; Sahadevan et al. 2023). However, universal electricity access enables households to move away from traditional cookstoves, a major cause of indoor air pollution and associated respiratory disease and infections (11.4.2), especially for women. However, there is some conflicting evidence of the benefits (Checkley et al. 2021; Rasul et al. 2025) of access to clean cooking that needs to be assessed, especially for Indigenous Peoples. Although traditional cooking methods are typically without monetary cost, it is important to consider the economic implications of subsidizing this new technology for Indigenous Peoples' families and local communities (World Bank 2020), otherwise a new inequity may arise.

In both Transformation Pathways, 300 million more people have access to safely managed water sources by 2050 and nearly 1 billion more people have access to safely managed sanitation than under Current Trends. The cost of this expansion is estimated to be US$ 1.2 trillion.

11.5.2 Good health

As already outlined, the Transformation Pathways improve human health by alleviating hunger and undernourishment, expanding access to water and sanitation services and reducing air pollution. Consequently, the overall burden of disability-adjusted life years is reduced by up to 2 per cent annually, enabling more than 750 million years of healthy living by 2050, increasing to over 3 billion by 2100 in both Transformation Pathways.

By reducing the prevalence of both communicable and noncommunicable diseases (**Figure 11.24**) the Transformation Pathways avert nearly 9 million premature deaths by 2050 and more than 50 million by 2100. Communicable disease deaths disproportionately affect young children (GBD 2019 Child and Adolescent Communicable Disease Collaborators 2023) and the Transformation Pathways can rapidly reduce child mortality rates. Neonatal and under-5 child mortality rates are projected to reach the respective SDG target values three years ahead of the Current Trends. Mortality from noncommunicable diseases is also improved by reducing heart disease, already the top cause of mortality globally, through improved diets and air quality (Reddy and Katan 2004; Jankovic et al. 2015; Naghavi et al. 2021). This reduction is prominent under the Behaviour-focused Transformation Pathway, which results in 1.4 million fewer annual deaths from heart disease by 2050, compared with 0.5 million in the Technology-focused pathway.



As a result of the Transformation Pathways leading to a healthier and longer-living population, age-related deaths become more prevalent. The Transformation Pathways increase overall life expectancy by 0.1 years in the first few decades and 0.3 years by the end of the century, in addition to improvements seen in the Current Trends pathway. In low-income economies, life expectancy improves by more than one year by the latter half of the century in the transition pathways.

11.5.3 Fair and just societies

Section 10.6.3 shows that poverty is expected to fall gradually in the Current Trends projection, but that progress is not sufficient to meet development targets. While the Transformation Pathways do not include interventions to address poverty directly, by avoiding substantial climate and environmental damages and fostering economic growth, both Transformation Pathways result in more than 150 million people escaping extreme poverty compared to the Current Trends (**Figure 11.23**).

One measure of just societies is their ability to adequately distribute resources to the most vulnerable populations (Hancher et al. 2022). **Figure 11.25** highlights the difference in extreme poverty rates between women and men in different regions. The large imbalances in regions with significant poverty is further mitigated in all projections, but at a faster rate

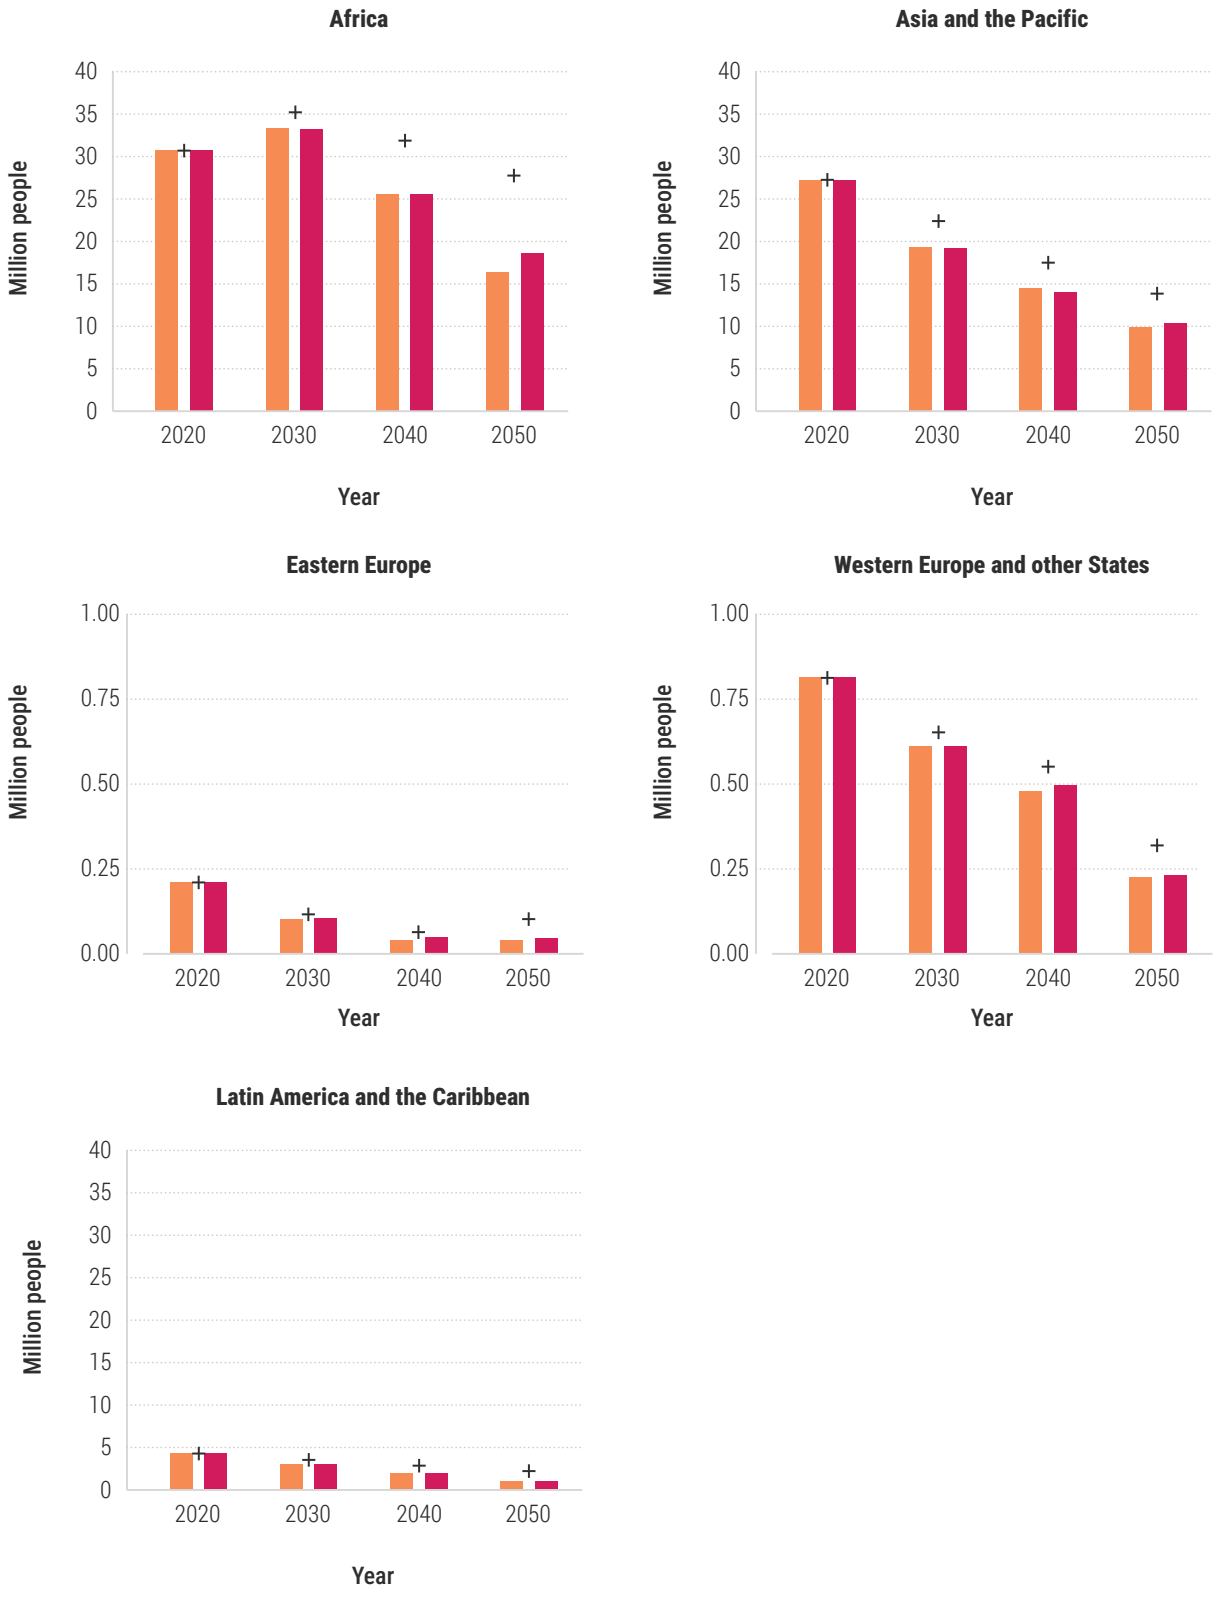
Figure 11.24: Annual avoided deaths of the transformation pathways relative to the current trends

Source: IFs model

in the Transformation Pathways. However, by 2050, some of this imbalance remains, particularly in Asia and the Pacific, and Africa, highlighting the need for extra effort to ensure gender justice.

11.5.4 Security

Expected economic growth will generally improve global security in the Current Trends scenario (10.6.4). There is evidence that worsening environmental conditions can lead to conflicts over increasingly scarce natural resources (Abel et al. 2019). Environmental crises may also lead to greater migration, which could cause additional strain in destination countries, further increasing conflicts (Hegre and Sambanis 2006; Goldstone et al. 2010; Mach *et al*. 2019). By easing the pressures on natural resources and averting environmental crises, the Transformation Pathways could reduce the risk of conflict and instability in the long run. Additionally, overall improvements in human development and well-being lower the likelihood of violent conflict (Fearon and Laitin 2003; Hegre and Sambanis 2006).



Several other determinants of security are not addressed directly in the Transformation Pathways. For instance, there is evidence that political institutions are an important determinant of the risk of armed conflict (Hillesund et al. 2018). Other drivers include horizontal inequalities, social ties and movements (Forsberg 2014; Nagle 2016). Global cooperation to strengthen migration governance in line with the Global Compact for Safe, Orderly and Regular Migration, as well as inclusive peacebuilding efforts, can mitigate the risks of environmentally induced displacement, migration, and conflict (International Organization for Migration 2024).

Security outcomes of the Transformation Pathways should be understood as highly uncertain, especially at country level. Models that forecast future patterns of conflict rely on structural factors and historical patterns of conflict, and these may change over time, or even not hold for future conflicts (Hegre *et al*. 2016; Bowlsby et al. 2020; Moyer et al. 2023). Unintended consequences of sustainable development that are not factored into these models may also exacerbate insecurity (Moyer 2024).

11.5.5 Economic impacts and employment

The Transformation Pathways imply major changes in the economic and finance systems, with important implications for local economies. The outcomes depend on a combination of factors: the capacity of different

Figure 11.25: The number of women in excess of men living in extreme poverty (less than US$ 2.15 per day at PPP in 2017 US$) for the ages 24-55, by UN regions and pathway across time

Note: Figure does not show absolute number of women in poverty, but rather the imbalance of female poverty with respect to men.

Source: IFs 8.26.2 model

countries to supply essential materials and services, their consumption and production patterns' capacity to change, their financial profiles and the composition of population and labour force, among others.

The costs entailed in the Transformation Pathways – ignoring the benefits of avoided climate change – imply a small but negative impact on GDP, leading to a 1.5 per cent lower cumulative GDP over the 2025–2100 period when compared with the Current Trends. This is in line with empirical findings regarding the economic impacts of decarbonization (IPCC 2023a; Fujimori et al. 2023). The negative consequences are mostly visible in the short to medium term as most of the required investments are generally more expensive than the carbon-intensive incumbents, and the infrastructure is not in place. The benefits of most of the options are only visible in the long term, including energy and operating-cost savings and higher disposable income.

It is important to note that these GDP effects only account for the cost of the transformation and the effects of emissions pricing. They also exclude the damage costs arising from climate change and environmental degradation in the Current Trends. Including these costs of inaction, the Transformation Pathways display

Table 11.2: Required system transformations between 2020 and 2050 to meet the goals set out in Sections 9.3

Climate change	Biodiversity loss	Halt pollution	Land degradation	Food security	Water access	Energy access
Limiting total energy demand via lifestyle changes or increased efficiency, leading to energy intensity (per economic output) reduction of around 60–75 per cent. Rapid decarbonization of the energy system with emission intensity of energy supply reducing by 10–15 per cent per year and increasing the share of renewables to around 50–55 per cent of total energy supply, and 85–95 per cent of electricity supply. Consistent scale-up of renewables by 5–7 per cent per year. Increase the electrification rate of final energy to at least 45 per cent. Land use acting as CO2 sink with up to 5Gt CO2/yr each from land use and bioenergy with CCS. {11.3.1; 11.4.1}	Protect 30–50 per cent of land, across all biomes and ecosystems. Increase forest and other natural land areas by up to 660 Mha. {11.3.2; 11.3.4}	Improve air pollution control technology. {11.4.2}	Protect 30–50 per cent of land across all biomes and ecosystems. Restore former agricultural lands. Increase forest and other natural land areas by up to 660 Mha. Regenerate degraded lands increasing terrestrial carbon stocks by up to 30 Gt of carbon. {11.3.2; 11.3.4; 11.4.3}	Dietary changes reducing animal product consumption by 20–45 per cent in line with healthy diets (share of crops consumed increasing from 82 per cent to 90 per cent). Improving crop yields (0.7–0.9 per cent per year). Reduction of food waste by up to 50 per cent. Improve food distribution equivalent to best-performing countries today. {11.3.5; 11.3.2; 11.5.1}	Increased access to water for an additional 1 billion people. Use advanced irrigation measures (drip irrigation, rainwater harvesting). {11.3.5; 11.4.6; 11.5.1}	Complete phase-out of traditional cookstoves and provide access to modern stoves. Universal access to electricity, particularly in rural areas, with 120 million new connections above baseline. Funnel revenues from emission pricing towards improved energy access for poor households. {11.3.1; 11.3.5; 11.5.1}

Note: the associated synergies and trade-offs between these goals are elaborated in Table 11.3

no GDP loss by 2050, and benefits of 6 per cent by 2070, increasing to over 25 per cent by 2100. Thus, despite the upfront costs, the Transformation Pathways result in an extra US$ 20 trillion per year of value by 2070 and over US$ 100 trillion per year by 2100. These results are in line with other assessments of the costs of transformation and climate damage across a variety of methods (Piontek et al. 2021; Riahi et al. 2022.

The short-term economic costs of both Transformation Pathways lead to small but negative effects on short-term employment, with unemployment rates about 1–2 per cent higher than the Current Trends between 2030 and 2040 and decreasing thereafter. There are key differences concerning the employment characteristics of the pathways, with the Technology-focused pathway having higher employment growth in industry and manufacturing, while the Behaviour-focused transformation increases employment in public transportation, agriculture and energy. Labour intensity increases in the Behaviour-focused pathway due to lower technological progress and a focus on activities that are more labour-intensive.

11.6 Synergies in the transformation

Table 11.2 summarizes the massive system transformations that are required to avert global environmental crises. By taking advantage of synergies across the systems, it is nevertheless possible to achieve all the goals simultaneously, without necessarily having to compromise. The integrated modelling helps explore these cross-system links, with specific transformations either acting as enablers or posing risks across the systems. **Table 11.3** points out the synergies to be harnessed and the possible risks that need to be averted or managed.

Lower demand enabled by lifestyle changes through the Behaviour-focused transformation or efficiency improvements through the Technology-focused transformation – especially when compared to the Current Trends but even compared to 2020 – makes it significantly easier to meet climate goals. This also enables an easier and more rapid uptake of renewables, with a lower demand for natural resources. This is particularly important since, even with the scale-up of renewable electricity in recent years, an overall increase in total energy demand means emissions have not reduced accordingly (IEA 2023a; IEA 2023b). Reducing energy demand also limits the risk of depending on prospective and unproven technologies such as CCS and CDR. Yet the pathways still depend to an extent on CO_2 removal, since the remaining carbon budget to meet the 1.5°C target is very tight, as highlighted in the IPCC's 6th Assessment Report (IPCC 2023b). Decarbonizing the energy system also has associated benefits for water demand and quality, due to the reduced requirement of cooling water for thermal power plants (11.3.1). Furthermore, the energy system projections, together with implications for the demand for infrastructure and changes in material flows, lead to significantly lower demand for materials.

These changes have important implications for the land system. Lower energy needs reduce the demand for biomass and bioenergy, leading to reduced land requirements, which are significant in other climate change mitigation pathways (Daioglou et al. 2019; Fujimori et al. 2022). However, the land system benefits most from a reduction in areas dedicated to agricultural production. Thus, the Behaviour-focused transformation presents fewer risks due to its significant dietary shifts and reduction in land for livestock and does not depend on massive increases in agricultural yields. This alleviates the need for trade-offs concerning biodiversity, fertilizer use, water use and pollution, while also freeing up of huge tracts of land. This makes it easier to align with associated goals and to make the land system a net CO_2 sink, contributing to climate change mitigation. Focusing purely on nature protection and restoration could also contribute to these goals, but without significant changes to the agricultural system, these measures could jeopardize food security by restricting land availability for food production.

Synergies across human well-being goals, beyond those represented in the modelling framework, may also be achieved if certain implementation bottlenecks can be overcome. Universal electrification requires equity solutions that overcome social stratification and income disparities (Dugoua, Liu and Urpelainen 2017) and opens possibilities for universal energy access to promote gender empowerment and more employment opportunities (Pearl-Martinez 2020; Dinkelman 2011; Das et al. 2023). Land-based mitigation through natural vegetation restoration and afforestation affects water availability (Filoso et al.

Table 11.3: Summary of possible synergies (green) and risks or trade-offs (red) that need to be negotiated to meet all the goals described in Section 9.3 and Table 9.1, repeated in the "diagonal"

Solutions across systems/ Implications, synergies or trade-offs	Implications for climate change	Implications for Biodiversity loss	Implications for pollution	Implications for land degradation	Implications for food security	Implications for clean water access	Implications for energy access
Solutions for climate change	**Limit global mean temperature increase to 1.5°C**	Reforestation/revegetation to create carbon stocks can also protect biodiversity Avoiding climate change-driven biodiversity loss, the main driver of biodiversity loss during the 21st century {11.3.2; 11.3.4}	Reduction of fossil fuels improve air quality {11.3.1; 11.4.2}	Land-based mitigation with natural vegetation restoration Land-based mitigation with planted forests (monocultures) or bioenergy production from energy crops could lead to land degradation {11.3.4; 11.4.3}	Avoided negative climate impacts on food systems improve supply of food Redistribution of carbon revenues can help increase food access for poor households Avoided economic damages from climate change, and improved skills workforce increase households' purchasing power Land-based mitigation could create competition for land which may disproportionately affect poor households' food security {11.5.5}	Reduced use of thermal power plants reduces water withdrawal and contamination Reduction in changes in precipitation and evaporation, and hydrology related climate impacts (water scarcity and flooding) Land-based mitigation with natural vegetation restoration (help to protect and restore water bodies) {11.3.1; 11.4.1}	Targeted provision of energy-efficient technologies can help poor households meet energy needs without increasing the overall burden on the energy system Redistribution of carbon revenues can help increase energy access for poor households Avoided economic damages from climate change, and improved skills workforce increase households' purchasing power Increased carbon prices on energy may be regressive and disproportionately affect poor households {11.5.5}
Solutions for biodiversity loss	Protected areas and natural vegetation restoration can act as carbon sinks {11.3.4; 11.4.1}	**No further loss of biodiversity by 2030, and an increase towards 2050**	Protected areas can act as a barrier for fires and deforestation, decreasing emissions and air pollution	Protected areas and natural vegetation can restore land quality {11.3.4; 11.4.3}	The protection of natural land may increase land competition, driving up food prices		

Table 11.3: Summary of possible synergies and risks or trade-offs that need to be negotiated to meet all the goals described in Section 9.3 and Table 9.1, repeated in the "diagonal" (cont.)

Solutions across systems/ Implications, synergies or trade-offs	Implications for climate change	Implications for Biodiversity loss	Implications for pollution	Implications for land degradation	Implications for food security	Implications for clean water access	Implications for energy access
Solutions for pollution	Decrease of some air pollutants and emissions from agriculture reduces climate change and may lead to less fossil fuel use Reduction of aerosols and sulfur emissions could increase warming {11.3.1; 11.4.2}	Decrease in air pollutant and nitrogen emissions reduces pressure on biodiversity Reduction in resource use, and associated land use {11.3.3}	**Limit population exposed to ambient PM2.5 to less than 20 per cent by 2030, and less than 10 per cent by 2050**	Reduced fertilizer use through increased efficiency or non-intensive agricultural practices	Averted crop yield losses from ozone pollution Lower fertilizer use may reduce crop yields and food availability {11.4.2}	Lower water pollution from more efficient or decrease in fertilizer use {11.4.5}	Rapid changes in the energy system could jeopardize equitable access to clean energy Use of modern fuels in line with energy access goals {11.4.2}
Solutions for land degradation	Protection of natural lands and terrestrial carbon stocks {11.3.4; 11.4.1; 11.4.3}	No deforestation, and large-scale restoration Agricultural practices to increase carbon in the soil {11.3.4}		**Halt loss of natural land by 2030, and increase carbon stocks in 30 per cent and 50 per cent of agricultural lands by 2030 and 2050**	The protection of natural land may increase land competition, driving up food prices		Reduced land availability for energy infrastructure

Table 11.3: Summary of possible synergies and risks or trade-offs that need to be negotiated to meet all the goals described in Section 9.3 and Table 9.1, repeated in the "diagonal" (cont.)

Solutions across systems/ Implications, synergies or trade-offs	Implications for climate change	Implications for Biodiversity loss	Implications for pollution	Implications for land degradation	Implications for food security	Implications for clean water access	Implications for energy access
Solutions for food security	Dietary changes leading to reduced animal product consumption reduce non-CO2 greenhouse gases and reduce deforestation/increase afforestation. Use of agricultural residues to provide bioenergy (possibly combined with carbon capture and storage leading to negative emissions) {11.3.2; 11.4.1}	Dietary changes leading to reduced animal product consumption free up a lot of land otherwise used for feed and grazing Improvements in crop yields (closing the yield gap) can free up land for restoration Nature-positive agricultural production methods Intensive use of agrochemicals {11.3.4}	Using regenerative and mixed-system agriculture, and increasing nitrogen-use efficiency Avoided nitrogen pollution from reduced livestock production and increased nitrogen-use efficiency Intensive use of agrochemicals {11.4.2, 11.4.5}	Using regenerative and mixed-system agriculture, and increasing nitrogen-use efficiency Avoided nitrogen pollution from reduced livestock production and increased nitrogen-use efficiency Intensive use of agrochemicals {11.4.2, 11.4.5}	**Achieve universal access to adequate food by 2050**	Using regenerative and mixed-system agriculture, increasing nitrogen-use efficiency, and improving water quality Dietary changes leading to reduced animal product consumption avoid nitrogen pollution Advanced water management techniques (drip irrigation, rainwater harvesting) can increase yields while conserving water Intensive use of agrochemicals and irrigation leads to a decrease in water availability and quality {11.4.5; 11.4.6}	Improved health can increase household purchasing power {11.5.2; 11.5.5}

Table 11.3: Summary of possible synergies and risks or trade-offs that need to be negotiated to meet all the goals described in Section 9.3 and Table 9.1, repeated in the "diagonal" (cont.)

Solutions across systems/ Implications, synergies or trade-offs	Implications for climate change	Implications for Biodiversity loss	Implications for pollution	Implications for land degradation	Implications for food security	Implications for clean water access	Implications for energy access
Solutions for clean water access						Appropriate irrigation methods can close yield gaps and increase agricultural production Wasteful irrigation may lead to water scarcity {11.4.6}	**Achieve universal access to safe water and sanitation by 2050**
Solutions for energy access	Access to modern fuels (particularly through electrification) reduces the use of polluting solid fuels, particularly coal, charcoal, and traditional biomass. Increased energy demand may put stress on energy system and decarbonization efforts {11.3.1; 11.3.3; 11.5.1}	Moving away from traditional biomass reduces interference on land	Access to modern fuels significantly reduces indoor air pollution, avoiding up to 1 million premature deaths {11.4.2}	Moving away from traditional biomass reduces interference on land	Access to clean energy improves health and gender equality and possibilities for increasing household purchasing power Possible competition for land for renewable energy {11.5.1; 11.5.2; 11.5.3}	Access to clean energy improves health and gender equality and possibilities for increasing household purchasing power {11.5.1; 11.5.2; 11.5.3}	**Ensure universal access to electricity and reliance on clean fuels**

Note: the table shows how specific solutions per system (rows) affect other systems (columns). Where available, sections in Chapter 11 that provide further details are also shown.

2017; Hoek van Dijke et al. 2023) and biodiversity (Atkinson et al. 2022). Another synergy relates to air pollution and biodiversity goals. Creating protected areas to halt the loss of biodiversity also decreases deforestation in tropical areas (Andam et al. 2008). Deforestation is directly linked to air pollution through forest fires (Reddington et al. 2021; Burke et al. 2023) and consequently to health issues. Finally, there is the crucial issue of reducing the use of agrochemicals, particularly pesticides, due to their consequences for human health (Tang et al. 2021; Gerken et al. 2024). All these examples reinforce the importance of a holistic understanding of the implications of the solutions adopted.

Reduced pressure across the systems, bringing the demand for natural resources more in line with planetary boundaries, is the key enabling factor allowing multiple goals to be met simultaneously (Rockström et al. 2009). This reduction, presented here in the form of efficiency improvements and lifestyle changes, creates important synergies that make meeting multiple goals possible and complementary. This analysis further highlights that benefits across multiple systems arise from actions that are not siloed or focused solely on a single environmental or social crisis (McElwee et al. 2025). Instead, response options should be streamlined and consistent, with the aim of exploiting synergies and minimizing trade-offs.

11.7 Challenges and opportunities

11.7.1 The necessary governance transformation as an enabler

The two Transformation Pathways present alternative futures that achieve multiple environmental and social goals. The implemented measures and associated synergies evident when comparing transformation of systems could result in win-win situations. However, such positive outcomes are also driven by implicit and explicit assumptions in the narratives and the model framework used. Both Transformation Pathways depend on effective regulation, high levels of technological development, and well-regulated markets, where externalities are appropriately identified and priced. The presence of strong governance, effective policymaking and legitimate and well-functioning institutions that mediate social and political conflicts is implicit in both pathways. Synergies and trade-offs can also play distinct roles in different geographic and socioeconomic contexts. Policy and legal frameworks that recognize Indigenous Knowledge and Local Knowledge, perspectives, and responses can help inform how best to exploit theses potential synergies (Office of the United Nations High Commissioner for Human Rights 2021; Carmona et al. 2024; Rahmah and Sulstyono 2024).

There are also significant infrastructural and distributional challenges to be overcome. For instance, the pricing of externalities, if not deployed correctly, could exacerbate inequality and the associated social problems (Emmerling, Andreoni and Tavoni 2024). Scaling up renewables will increasingly face integration, land-use, infrastructure, skills and critical mineral bottlenecks, especially concerning storage, interconnectivity, and ageing electricity networks (Jagger, Foxon and Gouldson 2012; Wang et al. 2022; IEA 2023a). This is also reflected in the goal of achieving universal electricity access, which requires a massive expansion of electricity networks, particularly in areas that may involve significant costs (11.3.1). Similarly, concerning hunger and malnutrition, while the Transformation Pathways solve the problem of food availability, they are insufficient to solve the problem of access. Eliminating undernourishment requires additional distributional measures (Aziz et al. 2021; Fabian, Gomez and Rosete 2023) to achieve near equality in the distribution of calories – a massive challenge, especially in countries with high undernourishment rates (11.5.1).

Rebound effects may be significant, especially in the Technology-focused pathway, with its very high levels of technological improvements and efficiency gains. These effects need to be controlled through additional regulation and appropriate pricing of potential externalities from increased intensification. For example, increased efficiencies and agricultural yields in the Technology-focused Transformation Pathway reduce agricultural land needs, opening space for natural vegetation restoration. However, using this land for planted forest monocultures may aid carbon sequestration but also affect biodiversity and water. Thus, additional measures would also be needed to prevent the negative effects of intensive agriculture on biodiversity, soil quality, water availability and pollution. In the Behaviour-focused pathway, high levels of rebound are pre-empted through the narrative of sufficiency and a cultural shift in the

relationship between human settlements and the natural environment, leading to lowered pressures.

The modelled pathways assume that transformation takes place rapidly and without economic and social friction. Accordingly, both narratives need to deal with the social implications of reduced consumption, technology, and the adoption of automation, including artificial intelligence. This includes the effects on employment, energy and resource use, culture and identity. Appropriate educational and training systems, as well as safeguards for employment and other impacted activities, are needed. The transitions may face significant opposition from vested interests – across all the systems and social strata – which prefer the status quo. This points to a conclusion that the required transformation is principally a cultural and political one, requiring fundamental changes to the relationship we have with nature.

11.7.2 Implications for Indigenous Peoples and other communities

An often-overlooked challenge is the potential negative impact of the adopted solutions on some populations, particularly Indigenous Peoples and households in rural areas. This is especially true for the *Technology-focused* pathway whose narrative considers the transition to a more urbanized world and the continued dominance of large enterprises, for example, agribusiness. The expansion of large enterprises for renewable energy (wind and solar plants, hydropower), highly efficient agribusiness, and mining (for required rare earth metals for the energy transition, for example) is already leading to displacement and conflicts – directly or indirectly – by reducing local community access to land and water, as well as increasing the risks of contamination and other environmental and social impacts (Chiarelli et al. 2022; Comissão Pastoral da Terra [CPT] 2022; Peixoto, Soares and Ribeiro 2022; Kennedy et al. 2023; Sales and Sales 2023; IPES-Food 2024; Aguiar et al. 2025). As urban centres in low- and middle-income countries are often chaotic and unplanned (Christiaensen and Todo 2013; Nagendra et al. 2018), additional solutions will be needed to guarantee economic alternatives, appropriate services and human well-being, while avoiding urban sprawl, land-grabbing and poor planning.

For Indigenous Peoples to benefit fully from any transformations, it is vital to safeguard the transmission of Indigenous Knowledge and the practice of traditional ways of life, which are closely associated with the care and ownership of their territories. A transition towards socioenvironmental justice and sustainability requires recognizing the knowledge systems, respecting the individual and collective rights of Indigenous Peoples and integrating their worldviews and actions into the search for global solutions (IK & LK Dialogues 2025).

There are also opportunities to learn from and build upon Indigenous Peoples' practices and co-create solutions (Ford et al. 2020; Ogar, Pecl and Mustonen 2020; Food and Agriculture Organization [FAO] 2021; Turner, Cuerrier and Joseph 2022), as they have demonstrated a commitment to caring for the environment in a sustainable manner (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem [IPBES] 2019; FAO 2021). Self-autonomy and the implementation of free, prior and informed consent are key enablers in processes where Indigenous Knowledge is mainstreamed (Mistry, Bilbao and Berardi 2016; IK & LK Dialogues 2025).

11.7.3 Opportunities to be harnessed

Despite the challenges, the Transformation Pathways also present multiple opportunities. An obvious example would be the avoided costs of inaction described in Chapter 10: in the long term, climate damage alone could reduce future GDP by US$ 20 trillion per year in 2070 and over US$ 100 trillion per year by 2100, based on median estimates (10.6.5). The estimated costs of transformation are considerably smaller: US$ 1 trillion per year until 2050, or approximately 1 per cent of global GDP in 2050 (11.5.5), with significant benefits thereafter.

Further socioeconomic benefits can arise from the transformation. The appropriate and effective pricing of environmental and social externalities can help reduce poverty through the redistribution of revenues. Additionally, the Transformation Pathways show a potential positive effect from the requirement of highly skilled labour and the resultant improved household income.

An overarching theme of this chapter is the enabling effect of reducing the demand for primary resources. This encompasses lifestyle changes in energy and food consumption, adoption of better technologies and techniques including Indigenous Knowledge and Local Knowledge, efficiency improvement of different processes, reduction of waste and promotion of circularity, or combinations of these. With safeguards on natural capital and equitable distribution of resources,

Credit: siwabudv/Envato

addressing the global environmental crises while achieving important human development goals is entirely possible. If appropriately implemented, the transformation of economy and finance, energy, land, materials/waste and environmental systems can help improve the state of the environment and the quality of life for millions of people. The foremost challenge and opportunity in achieving the goals is to simultaneously promote inclusive and thriving societies while recognizing the role and contributions of different genders, as well as Indigenous Peoples' and local communities and practices.

Chapters 12–18 build upon the insights presented here to identify specific solution pathways involving necessary conditions, actors and levers that can accelerate the transformation. Chapters 19 and 20 further explore the required transformation from a regional perspective. Finally, Chapter 21 synthesizes all the insights to assess how sustainable transformations can be accelerated. This puts the focus squarely on the question of how to achieve the transformations while optimizing the synergies and minimizing potential trade-offs.

Appendix 11.1: Narratives quantification and mapping to solution pathways

	Behaviour-focused transformation		
	Narrative	**Solution pathways mapping**	**Modelling protocol (quantification assumptions)**
General assumptions	Goals are achieved through lifestyle, behavioural and value changes aligned with the sufficiency worldview. It envisions a future of regionalized economies where increased societal awareness of global environmental crises drives a shift towards sufficiency. The transformation is guided by principles of sharing, reciprocity, responsibility and care, aiming to reconcile human well-being with ecosystem health. Multiple forms of knowledge are combined, including mainstream science and Indigenous Peoples' and local communities' philosophies, practices and values.	**n.a.**	GDP – Current Trends (SSP2) Population – Current Trends (SSP2) Inequality – Decreased GINI coefficient (SSP1) Urbanization – Lower than SSP2 (based on SHAPE Project Resilient Communities Scenario) (SDP-RC) Regionalization – Increasing trade barriers (based on SSP3). Trade and flows of labour/capital are still allowed, but at a lower extent than the Technology-focused pathway Technology: • Technology efficiency improvement – Medium • Availability of prospective technologies – Some • Technology adoption – Medium/High • Reference learning rates Climate policy applied globally, aligned to meeting a 1.5°C target with low overshoot.
Economic systems	Reduction of externalities mainly through a combination of pricing and non-pricing instruments. Investments in technological and social solutions oriented towards enabling human and nature well-being.	S14.4 Making sustainability core in economic governance	A mix of standards, mandates and prices drives changes. Internalization of externalities through carbon prices.
Circularity	Low material footprints due to reduced conspicuous consumption and a digitally supported sharing economy. Repairing, refurbishing and recycling become the norm.	S15.5 Circular society pathway	Material demand follows energy service demand. Increased renovation/refurbishment compared to reference. Recycling rates increased above reference, following best current practices.
Energy systems	Behavioural and lifestyle changes lead to reductions in energy demand in rich regions, while middle- and lower-income regions catch up as basic energy services are satisfied. Emergence of "prosumers" facilitated through small-scale electricity generation. Local renewable resource endowments dictate energy systems, including wind, solar and biomass, leading to high regional variability in energy systems. For high-density urban and industrial environments, deployment of larger-scale technologies also takes place. Microgrids, demand-side management and distributed storage are scaled up to deal with variability.	S16.1 Provide environmentally sustainable, safe, reliable, and affordable energy access and clean cooking, and eliminate energy poverty for all S16.2 Improve energy management S16.3 Decarbonize and transition away from fossil fuels S16.4 Shift to a responsible and sustainable Critical Energy Transition Mineral Value Chain	Electrification levels: Medium – endogenous. Universal access to electricity by 2050. Use of traditional fuels – Complete phase-out by 2050. Electrification of final energy > 40 per cent by 2050. Increased share of communal and small-scale technologies (i.e. rooftop PV, onshore wind). Limits to CCS: • BECCS < 3 GtCO2/yr • Fossil CCS < 6 GtCO2/yr Demand for energy services: Reduced compared to Current Trends. Industry/Commercial: • Lower demand for industrial and commercial products (approx. 25 per cent reduction). Residential: • Higher occupancy rates – approx. 20 per cent higher. • Lower floorspace – Limit to 35m2/cap. • Lower appliance ownership (or communal use of appliances). No ownership of multiple instances of the same appliance. Limit ownership of appliances not necessary for decent living (e.g. clothes dryers). • Lower cooking energy demand by approx. 25 per cent (shared meals, etc.). • Lower demand for heating/cooling by adjusting thermostat settings.

Appendix 11.1: Narratives quantification and mapping to solution pathways (cont.)

	Behaviour-focused transformation		
	Narrative	**Solution pathways mapping**	**Modelling protocol (quantification assumptions)**
Energy systems			Transport: • Lower demand of passenger and freight km. Approx. 75 per cent of reference case Bioenergy demand: • Limited to 20 EJ/yr from energy crops • Lower availability from residues as an increased fraction (>50 per cent) left on the field for ecosystem services • Total availability of primary bioenergy approx. 70 EJ/yr
Food systems	Shift from input-based, to biodiversity-based practices. Increase the use of mixed systems and Indigenous Knowledge and Local Knowledge in production. Focus on rainwater management to increase yields on rain-fed cropland. Community-based food production and distribution reduce waste. Strong shift to plant-based foods and sustainable diets. Lower demand for industrial and processed foods, with an emphasis on the need to recover ancestral foodways as survival strategies in times of food crisis.	S17.1 Shifting to environmentally sustainable and healthy diets S17.2 Improved crop, livestock and aquatic food production and land use systems S17.3 Reducing loss and waste and increasing circularity S17.5 Restructuring the food industry market structure and trade	Agricultural management: • Crop yields – Medium increase, especially in regions/countries with large yield gaps • Livestock efficiency – Same as Current Trends scenario • Irrigated area – Lower increase in irrigated area Food distribution – SSP1 (based on Hasegawa et al. 2015). Dietary Patterns – Reach EAT-Lancet in 2050 (Willett et al. 2019): 50 per cent decrease in meat consumption, 100 per cent increase in nuts, vegetables, fruits and legumes). Food-waste reduction – Reduction in food waste losses by 50 per cent compared to Current Trends Water management • Irrigation efficiency – Same as reference • Increased infiltration – Medium improvement (gradual increase between 2020–2040) • Soil moisture conservation – Medium improvement • Rainwater harvesting – Medium improvement • Erosion prevention – Very high • Wastewater treatment – High Nutrient management • Nitrogen Use Efficiency (NUE) - Best between reference and 50 per cent of maximum NUE • Phosphorus efficiency – High
Environmental systems	Nature and the environment are culturally valued and mutually beneficial with human settlements, aligned to the "Nature as Culture" defined in the IPBES Nature Futures Framework (NFF) (Pereira et al. 2020). Guided by principles of land-sharing, there is an increase in mutually beneficial and sustainable use of protected areas (terrestrial, freshwater and marine) aiming for 50 per cent of the world in 2050. Natural regrowth/restoration on abandoned agricultural lands due to changes in the food system provides a carbon removal service, helping mitigate climate change.	S18.1 Enhancing ecosystem services through regenerative systems and biodiversity conservation S18.2 Nature-based solutions for conservation, restoration and adaptation	Protection of terrestrial ecosystems: Regulatory – protected areas (at least 30 per cent protection of natural ecosystems, aiming towards 50 per cent) and peatland protection Protection of groundwater availability and environmental flows (70 per cent) plus restricted groundwater use. Land-based mitigation limits – Only allow natural regrowth on abandoned lands.

Appendix 11.1: Narratives quantification and mapping to solution pathways (cont.)

	Technology-focused transformation		
	Narrative	**Solution pathways mapping**	**Modelling protocol (quantification assumptions)**
General assumptions	Goals are achieved by gains in efficiency through innovation and technological solutions. It envisions a future characterized by a largely globalized and urbanized economy with significant trade, in which society relies on price-mediated and technological solutions to solve the global environmental crises and transform current systems.	n.a.	GDP/Population/Inequality – Same as Behaviour-focused Urbanization – Current Trends (SSP2) Regionalization – Increased free trade and policy harmonization (SSP1) Technology: • Efficiency improvement – Very high • Availability of prospective technologies – High • Technology adoption – High • Learning rates – High Climate policy applied globally, aligned to meeting a 1.5°C target with low overshoot.
Economic systems	Reduction of externalities through pricing mechanisms and efficiency gains. High investments in technical solutions to environmental and social problems.	S14.1 - Internalizing the externalities (correcting pricing)	Prices in general are the main driver of change in the global economy. Internalization of externalities through carbon prices.
Circularity	Design driven by cradle-to-cradle concerns. Increased efficiency and reduced waste. Efficient modular design in buildings increases their longevity and ability to be refurbished. Monitoring, reviewing and redesigning of products, associated with the implementation of necessary infrastructure, leads to recyclability and high recycling rates.	S15.1 Designing out waste/ Designing circularity into the full life cycle of products	Lower demand via improved design, material substitution. Very high recycling rates near technical potential of recycling by 2050. High levels of renovation/refurbishment of buildings.
Energy systems	Supply-side investments; focus on efficiency, clean energy, interconnectivity and high levels of electrification. Technological solutions, including power-to-liquids, biofuels, hydrogen, and carbon capture and storage (CCS) are also prevalent if the economics are appropriate. Nuclear energy and fossil fuels are used sparingly, and technological innovations help to reduce their negative impacts. Centralized distribution networks, large-scale supply and storage of electricity, and large-scale grid interconnections with reduced transmission losses.	S16.1 Provide environmentally sustainable, safe, reliable, and affordable energy access and clean cooking, and eliminate energy poverty for all S16.2 Improve energy management S16.3 Decarbonize and transition away from fossil fuels	Electrification levels – High Universal access to electricity by 2050. Use of traditional fuels – Complete phase-out by 2050. Electrification of final energy > 45 per cent by 2050. Advanced technology (hydrogen, bioenergy with carbon capture and storage [BECCS], direct air carbon capture and storage etc.) available by 2030, but only used if cost-competitive. Preferential deployment of large-scale renewable projects (hydropower, offshore wind, etc.). Globally best-available technology adoption by 2040. Limits to carbon capture and storage (CCS) • BECCS < 5 GtCO2/yr • Fossil CCS < 8 GtCO2/yr Demand for energy services (all sectors) – Medium (SSP2). Bioenergy demand – Price-based • Limited to 50 EJ/yr from energy crops • Total availability of primary bioenergy approx. 120 EJ/yr

Appendix 11.1: Narratives quantification and mapping to solution pathways (cont.)

	Technology-focused transformation		
	Narrative	**Solution pathways mapping**	**Modelling protocol (quantification assumptions)**
Food systems	Agricultural intensification and technological solutions, aligned to the land-sparing principle in the environmental system, i.e. producing more in less area, freeing land for nature restoration and conservation. High efficiency, adoption of efficient irrigation and automated agricultural production. Substitution of animal products by novel foods such as cultured meat, further decreasing the need for pasture area. Technical means are adopted to tackle food waste and losses.	S17.1 Shifting to environmentally sustainable and healthy diets S17.2 Improved crop, livestock and aquatic food production and land use systems S17.3 Reducing loss and waste and increasing circularity S17.4 Novel foods and production processes S17.5 Restructuring the food industry market structure and trade	Agricultural management: • Crop yields – Increase in productivity (similar to SSP1) • Livestock efficiency – Increase in productivity (similar to SSP1) • Irrigated area – Higher increase in irrigated area (similar to SSP1) • Irrigation efficiency – Increase in irrigation efficiency above Current Trends Food distribution – Medium (SSP2). Dietary patterns – 50 per cent reduction of meat consumption in High-Income Countries (HIC) by substitution with cultured meat. Food-waste reduction – Reduction in food waste losses by 50 per cent compared to Current Trends. Water management: • Reservoirs – more reservoirs • Erosion prevention – high • Wastewater treatment – very high • Increased infiltration – none • Soil moisture conservation – none • Rainwater harvesting – none Nutrient management: • Nitrogen Use Efficiency (NUE) – Best between reference and 70 per cent of maximum NUE • Phosphorus efficiency – very high
Environmental systems	Transformation is guided by the principle of sparing, for the efficient use of non-protected areas allowing the regeneration of large areas of natural vegetation. Protected areas in biodiversity hotspots. Natural vegetation covering more than 30 per cent is pursued, combining at least 30 per cent fully protected natural ecosystems and REDD policies, aligned to the Nature for Society and Nature for Nature IPBES NFF perspectives. Planted forests that can act as carbon sinks are used to help with climate change mitigation.	S18.1 Enhancing ecosystem services through regenerative systems and biodiversity conservation S18.2 Nature-based solutions for conservation, restoration and adaptation	Protection of terrestrial ecosystems: • Focus on carbon sequestration/price-based • Some land-zoning for biodiversity protection (at least 30 per cent protection of natural ecosystems and REDD policies) • Peatland protection Protection of groundwater availability and environmental flows – none Land-based mitigation limits – Maximum 500 Mha – Allow use of planted monoculture forests.

Solution Pathways Chapeau

Internationally agreed environmental, social and economic goals can be realized by taking unprecedented, ambitious and coordinated whole-of-government and whole-of-society approaches. This entails transforming the inter-connected economic/financing, materials/waste, energy and food systems, and improved environmental management. The strong interconnections between the systems (**Figure C.1**) means that systems transformation depends on the parallel co-development and co-implementation of the solutions with diverse actors, breaking policy silos, improved governance, redefined economic and market infrastructures and revised financing and valuation principles. Placing the environment and human well-being first are all critical to improving coordination between the systems (*well established*).

Recognizing and leveraging solutions within one system that create positive synergies and benefits across all systems, while avoiding those that may cause unintended harm to others is vital. This includes embracing the principles of a circular economy, fostering shifts in values and behaviors (**Box 1**), ensuring that solutions are fair and equitable, and integrating diverse perspectives and knowledge systems, with particular emphasis on Indigenous Knowledge. Solution pathways all require transformation of the economic/finance system, which drives the materials/waste, energy, food and environment systems (*well established*).

Figure C.1 Transforming systems: examples of solutions proposed in GEO-7

Each system chapter elaborates on these solution pathways and the actions required to accelerate transformation.

Economics & Finance

- Internalize environmental and social costs
- Reform subsidies to support sustainability
- Reflect long-term goals in economic planning
- Incentivize equitable and green economic activity
- Enhance inclusive and participatory decision-making

Environment

- Protect and restore ecosystems and biodiversity
- Strengthen resilience and governance of socio-ecological systems
- Capitalize on Indigenous and local knowledge systems
- Invest in nature-based solutions for conservation, restoration and adaptation
- Promote sustainable bioeconomy and its infrastructure

Food

- Shift to healthy and sustainable diets
- Reduce food loss and waste
- Promote sustainable and agroecological intensification.
- Secure land tenure and farmers' rights
- Strengthen local food systems and value chains
- Align agricultural subsidies with sustainability goals

Energy

- Ensure universal access to clean energy
- Expand energy efficiency and demand-side measures
- Scale up renewable and low-carbon energy
- Phase out fossil fuel subsidies and investments
- Support just and inclusive energy transitions

Materials & Waste

- Improve resource efficiency across sectors
- Promote circular design and production
- Reduce material use and consumption
- Extend product lifespans through reuse and repair
- Strengthen waste management, recycling, and infrastructure

Box 1: Changing behaviour: why Behavioural, Social, and Cultural (BSC) Insights Matter

Lasting transformation demands more than technological breakthroughs or policy reforms alone — it hinges on human behaviour. From individual consumption patterns to the priorities of groups and institutions, human behaviour is both a root cause of the global environmental crises, and a powerful lever for change (Keck et al. 2025; Merz et al. 2023).

Transforming systems requires transforming behaviours — individually, collectively, and structurally. Whether encouraging new technologies, policies or financial incentives, all solutions are impacted by, and lead to a change in, human behaviour (Shove 2010; Michie, van Stralen and West 2011).

Identifying target behaviours

To change behaviours, they must first be understood. Drawing on Behavioural, Social and Cultural (BSC) sciences can illuminate the complex web of factors that shape behaviours including: personal values, knowledge, emotions, habits, physical infrastructure, incentives, social norms and cultural narratives as well as historical, cultural and economic circumstances. These influences differ across regions, communities, and contexts. Ignoring this complexity risks designing ineffective policies (Slattery 2025).

Identifying 'target behaviours' to change is key to designing effective solutions. Target behaviours will vary depending on the solution goal and context. Selecting the right target behaviours can lead to widespread systemic change (Darnton, 2008; Gollwitzer and Sheeran, 2006; Meadows, 1999; Michie, van Stralen and West, 2011; Shove, 2010).

Designing solutions using BSC

Part D outlines how to design transformative solutions across systems using BSC insights. Frameworks such as the 'Capability, Opportunity, Motivation – Behaviour' (COM-B) system and the 'Easy, Attractive, Social, Timely' (EAST) framework offer structured, behavior-based approaches to intervention design (Michie, van Stralen and West 2011; Service et al. 2014). Embedding BSC approaches ensures that solutions are not only technically viable, but locally relevant, socially accepted, and sustained over time (Atkinson 2025; OECD 2025a). Behavioral change needs focused attention to properly scope interventions and recognize that cultural and lifestyle shifts take time to generate impact.

Rather than relying on a single intervention — like financial incentives or awareness campaigns — effective interventions combine strategies including: nudges, social influence, redesigned infrastructure, participation mechanisms, regulations, and storytelling. These can be tailored for different audiences — from individuals to institutions. However, there is no one-size-fits-all approach: what motivates change in one context may not work in another, especially when taking power dynamics, equity, and/or cultural identity into account (Atkinson, 2025; Rare and The Behavioural Insights Team, 2019).

Successful examples of applying BSC insights to environmental challenges include: reducing microplastic pollution through coordinated tech, policy, and community efforts in Malaysia (Goh et al. 2025), cutting household energy use in the Netherlands and Spain (Niamir et al, 2020), promoting sustainable mobility via social interventions in Lithuania (Vitkauskaite-Ramanauskiene, 2025), reducing food waste in Australia (Boulet and Lauren 2024), and boosting plastic bottle recycling in the US by targeting values and norms, with economic incentives like bottle deposits proving especially effective (Viscusi, Huber and Bell 2011).

Indigenous Knowledge and Local Knowledge Chapeau D

Recognizing the knowledge systems and sciences of both Indigenous Peoples as well as local communities, which have deep connections to place and nature, is critical in global policy and scientific frameworks for achieving just transitions through self-determination and global goals (Vaziri et al. 2020; Dawson et al. 2021; Just Transitions 2024). A systematic review found that sustainability transformations research often neglects Indigenous Knowledge and local knowledge, arguing that such knowledge contributes to more plural and inclusive solutions for such transformations and how to achieve them (Lam et al., 2020). Techno-scientific approaches to sustainability primarily focus on modelling and technological fixes rather than considering Indigenous Peoples rights and biocultural conservation. Conversely, critical social sciences understand sustainability transformations as inherently political processes. They recognize there are many potential sustainability futures and that achieving positive change requires democratic and pluralist engagement that amplifies marginalized and silenced voices, including those of women (Scoones et al. 2020; Burke et al. 2022).

This engagement incorporates the voices of Indigenous Peoples, acknowledging the human rights requirements for Free, Prior, and Informed Consent (FPIC) as outlined in the United Nations Declaration on the Rights

of Indigenous Peoples and Convention 169 of the International Labour Organization. Relevant political processes must also recognize the validity and potential of Indigenous Peoples knowledge, ontologies (ways of being based on distinct understandings of the nature of reality), and values more broadly beyond Indigenous Peoples' ancestral contexts. Recognition of Indigenous Knowledge and local knowledge in transformation pathways aligns with IPBES assessments that define transformative change as shifts in paradigms, goals, and values (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2019), including the moderation of market values and the amplification of solidarity and care values (IPBES 2022). Such ethics of respect, reciprocity, reverence, gendered equality and care are central to diversified Indigenous Peoples' conceptions of the good life – living well together as part of nature, in balance, with all creation, and lands having agency and value – challenging ethics, relations and structures of domination including patriarchy, governance, and control (Posey and Oxford Centre for the Environment Ethics and Society 1999; Reytar and Veit 2017; Brown and Verschuuren 2018; Sangha et al. 2019; IPBES 2022; Arora and Stirling 2023; IK & LK Dialogues 2025).

Indigenous Peoples can shape entirely new transformational pathways that are completely detached from the idea of sustainable development with its reliance on economic growth (Burke et al. 2022). Holistic understandings of lands, people, gendered knowledge and cultural relations contribute to the design of just transitions that address both environmental sustainability and human well-being (Welden, Chausson and Melanidis 2020; Riechers et al. 2021). They provide effective governance of living lands and create new forms of conservation that allow greater self-determination for Indigenous Peoples (Prosper et al. 2011; Hill et al. 2021; Paul et al. 2021). More broadly, Indigenous Peoples relational ontologies, values, and practices inspire sustainability action around the world (Nelson 2018; Bryer 2023). Indigenous Peoples stewardship of land and nature has often contributed to improving or maintaining biodiversity, land and soil quality and protecting their territories from extraction and misuse (Umeek 2011; Armstrong and Brown 2019; Díaz et al. 2019; ICCA Consortium 2021). There is clear evidence that Indigenous Peoples ontologies, values and practices have benefited and continue to benefit sea and landscapes by enhancing ecosystem function, regeneration, and biodiversity conservation (Balée 2013; Comberti et al. 2015; Ford and Nigh 2015; Reyes-Garcia et al. 2019; Thornton and Bhagwat 2021; Hoffman et al. 2021). Indigenous Peoples also resist unsustainable land management practices driven by capitalist resource extraction and appropriation, as well as cultural transmission pressures resulting from neo-imperialism, education, religion, and environmental pressures (The Atateken Declaration 2019; Makey et al. 2022; Fazito and Vargas 2023; Inman 2024).

As illustrated in Figure 1, Indigenous Knowledges will guide transformations towards sustainability, providing concrete guidance on actions related to the care of territory and life, as well as to energy, food, governance, and economies in socially just and culturally appropriate ways. Fundamental shifts and concrete practices for desired sustainable futures, as identified by participants in the GEO-7 Indigenous Knowledge and Local Knowledge Dialogues (IK & LK Dialogues 2025), include:

a) territorial and life care,

b) sustainable, social and solidarity economy,

c) responsible just energy transition based on self-determination and sovereignty,

d) education that fosters intergenerational transmission of Indigenous Knowledge and local knowledge and the revitalization of Indigenous Knowledge, cultures and languages, and

e) strengthening Indigenous Peoples' customary institutions and other forms of organizations, alliances and networks.

Instead of dismissing Indigenous ontologies, values and practices based on worldviews, and values of care and solidarity (IPBES 2022) or seeking to integrate them into scientific framings and paradigms, sustainability transformations will be better served by reparative actions that give greater space to Indigenous perspectives in decision-making processes and promote the broader uptake of such values (Stein et al. 2023).

Fig 1: Indigenous Peoples' perspectives on desired sustainable and just futures (IK & LK Dialogues 2025).

This figure shows Indigenous Peoples' perspectives on desired futures identified in the GEO-7 Indigenous Knowledge and Local Knowledge Dialogues

Credit: SakuraImageInc/Envato

The Indigenous Knowledge and Local Knowledge Dialogue of GEO -7 identified Indigenous perspectives on desired futures (IK & LK 2025). Figure 1 also illustrates the diversified yet common ways in which Indigenous conceptualizations of life give prominence to the ethics of care, reverence, reciprocity and respect, recognizing that humans are part of a web of life, a web characterized by relations of interdependencies, agency, obligations and sacredness. These ethics underpin self-determination and just transitions. Examples of Indigenous ontologies, values and practices are shown, such as Sumak Kawsay, Kametsa Asaike, Birgejumpi, and Ubuntu, representing aspects of biocultural diversity and conservation (Porsanger and Guttorm 2011; Chibvongodze 2016; Albó 2018; Caruso and Barletti 2019; IPBES 2022).

Chapter summary

Credit: liufuyu/Envato

There is widespread international agreement, backed by scientific evidence, that business as usual or continuous incremental improvements will not be enough to deliver global environmental goals. Fundamental transformations of key societal systems, aligned with efforts to deliver more peaceful, just and inclusive societies, are needed *(high confidence)* {12.2}.

The international community, supported by assessments of scientific evidence, has recognized the need for, increased urgency of, and difficulties associated with transformations of key human systems in the face of environmental challenges. Recent global environmental assessment reports have provided various definitions of system transformations and related challenges. Taken together, these reports underline a number of findings including the importance of system-wide changes beyond technological change and the need to align technological, economic, social and political changes. Additionally the reports highlight crucial needs for reconfiguring practices, norms, values and laws and for jointly supporting more sustainable systems while also reconfiguring unsustainable systems. Finally, the reports focus on the need to jointly address structural causes of unsustainability and injustice. However, what "fundamental system transformation" means, what system transformations entail, how to support them or how to track and evaluate progress all remain largely unaddressed.

There is a substantial and growing body of multi- and interdisciplinary scientific knowledge specifically

focused on system transformations, offering complementary perspectives on how societal systems have been or can be transformed, in a variety of sectors and contexts *(high confidence)* {12.3}.

Three social science perspectives engage directly with system transformations and their governance in the context of environmental and societal challenges:

- Socioecological perspectives focus on interactions among environmental components, including local environment, climate and natural factors, and human components such as local communities, cultural practices and institutions. They situate intentional transformative action within nested spheres of the practical, political and personal.

- Sociotechnical perspectives focus on the mutual shaping of technology and society, representing systems as semi-coherent bundles of technology, policy, industry, science, culture, and markets and users. They situate intentional transformative action as interventions targeted at whole systems and lock-ins.

- Socioeconomic perspectives focus on the interaction of economic and social systems, the scope for institutional frameworks and responses to modulate these systems. They situate intentional transformative action as structural interventions targeted at the underlying rules and orientations of economic systems.

These perspectives differ in terms of how system boundaries are drawn, how dynamics of transformations are represented, how future transformations are envisioned, and what are lessons for governance. Taken together, they can inform the evaluation and governance of intentional system transformation with improved resolution.

These three perspectives highlight the need for strategic approaches to the governance of system transformations, their interactions and interlinkages *(high confidence)* {12.3} {12.4}.

The feasibility and effectiveness of strategic efforts to support system transformations can be significantly improved if informed by guiding principles. This chapter proposes the following six guiding principles as requirements for the governance of system transformations:

Principle 1: Be explicitly targeted at whole systems and address underlying sources of lock-in related to current system configurations.

Principle 2: Jointly address opportunities and challenges in new and existing systems, through explicit choices resolving contradictions between what must be developed, phased out, preserved and avoided.

Principle 3: Articulate near and long-term solutions in sequences of action enabling constructive linkages between multiple temporalities and accounting for non-linear dynamics, recognizing justice for future generations and non-humans.

Principle 4: Be supported by new ways of dealing with uncertainties and anticipation.

Principle 5: Involve actors from different societal spheres and a plurality of ways of knowing and being, which implies deliberate forms of coordination, inclusion and participation, including representation of Indigenous Peoples.

Principle 6: Address power relations, vested interests and social inequalities through decisive political choices, guided by explicit notions of justice and respect for Indigenous Peoples' rights.

The implementation of these principles can be worked out through domains of intentional action, referred to as levers. These provide the scope for strategic approaches to system transformation in policy and practice – who and what drives change, how change is influenced, why it is accepted *(moderate confidence)* {12.5}.

The selected levers, namely Economics and Finance, Individual and Collective action, Knowledge and Innovation, Governance, and Capabilities, allow relevant social actors to make sense of difficulties for system transformation and to generate options for transformative action {12.5}. This chapter illustrates how system transformation principles can be implemented through this lever structure {12.6}.

Combining intentional actions in, across and beyond established levers is necessary to create capabilities and coordinated momentum for system transformation.

Credit: wirestock/Envato

Plurality and consideration of marginalized perspectives are essential to the intentional governance of transformative change *(high confidence)* {12.5}.

Plurality – recognizing different perspectives and ontologies – implies centring marginalized ways of being and knowing, as well as those of Indigenous rights holders and local communities with deep connections to the land, and addressing the deep underlying causes of unsustainability. Indigenous Peoples' and other relational worldviews recognize humans as part of nature, with entangled relations of sacredness, spirituality and interdependence. These relational worldviews produce culturally based teachings on obligations and reciprocities and on care for lands, for all beings – human and non-human, animate and inanimate – and for ancestors, as well as present and future generations. Such ontologies and ways of knowing, along with their associated practices, may challenge dominant worldviews, but they are consistent with global goals of peace, equity and justice.

The chapter concludes by focusing on the urgent responsibility of governments to catalyse system transformations. The key areas include orientation, alignment, navigation, and legitimacy of transformative goals and actions {12.7}.

Such coordination efforts are necessary to mitigate the risks of fragmented actions, counterproductive effects and further systemic lock-ins, as well as technocratic solutionism. This calls for a new policy design and a political culture that is inclusive and empowering, which raises the overall feasibility of system transformations by turning it into a widely shared societal project. Noting that governments must consider their attachments to existing structures, actors and interests, they also have particular responsibilities for creating favourable conditions for system transformations and the required governance changes. This responsibility for generating tangible change and hopeful futures can be seen as a way of reaffirming the relevance and legitimacy of democratic institutions for a better world.

12.1 Introduction

The previous chapters have set out the context and the issues ahead in the quest for a desirable world environment. As all Global Environmental Outlook (GEO) reports have shown, addressing systemic environmental challenges extends well beyond the remit of environmental policy and requires a focus on transforming underlying systems, as well as concerted efforts from all societal actors. While previous GEOs have provided policy-response solutions to the issues, as highlighted in Chapter 1, GEO-7 offers a fresh perspective for understanding and supporting system transformations based on the latest scientific evidence.

This perspective calls for establishing new theoretical underpinnings of the dynamics of system transformation, clarifying the means and scope for intentional action, and raising the importance of directionality as a new quality of the political culture for system transformations.

Preceding chapters have assessed the need for transformation based on scientific knowledge of environmental trends and drivers (Chapters 2–8), and provided future-oriented outlooks of the potential solution space from a technoeconomic modelling perspective and supporting archetypal storylines (Chapters 9–11). The purpose of this chapter is to delve further into the dynamics of system transformations, to identify key principles of transformation, and to determine the implications for intentional action. It does so with particular attention to the social, political and process feasibility of system transformations, as well as the necessary capability for intentional governance.

Section 12.2 discusses why system transformations are needed to address global environmental problems. It is based on global science-policy reports.

Section 12.3 summarizes knowledge contributions from three scientific perspectives engaging directly with system transformations within the social sciences, to identify the common evidence base for analysing and governing system transformations in the context of environmental and societal challenges:

- Socioecological transformations to sustainability
- Sociotechnical transitions to sustainability
- Socioeconomic transformations

Credit: tampatra/Envato

These literatures address transformations as a systemic challenge, related to inherent problems with how current systems are configured and locked in. They share some common ground as well as important contrasts.

Section 12.4 formulates six generic principles for system transformations, which are derived from the bodies of knowledge discussed in Section 12.3. They provide a general framework for analysing and evaluating the dynamics of system transformations according to specific criteria and conditions.

Section 12.5 translates the six principles for system transformations into requirements for intentional action. Approaching governance structures as a set of interacting levers (United Nations Environment Programme [UNEP] 2019; United Nations 2023) allows a detailed examination of the scope and locus of transformative interventions within and beyond existing domains of intentional action in policy and practice, referred to as levers.

Section 12.6 provides an exemplification of the approach by mobilizing illustrative cases, clarifying how each principle can become the object of actions within specific levers, across levers, and beyond established lever configurations.

Section 12.7 concludes the chapter by reviewing the governance mechanisms available for system transformation. In particular, it underscores the need for deliberative processes in the formulation of political solutions (United Nations 2023), acknowledging the complex and volatile world and the diversity of societal issues ahead. The section invites all policy actors to reconsider a new political practice of implementing system transformations, focusing on orienting, aligning, navigating and legitimizing key functionalities to safeguard a more stable and long-lasting directionality in governing for system transformations.

12.2 Science-policy rationales for system transformation

There is widespread international agreement, backed by scientific evidence, that business as usual or continuous incremental improvements will not be enough to deliver on global environmental goals and that fundamental transformations are needed (**Box 12.1**). Further, the international environmental community has significantly broadened its remit beyond assessments of the state of the environment towards greater involvement with the dynamics and governance of transformations, following a general trend from problem-based to solutions-focused assessments (Castree et al. 2014; Kowarsch et al. 2017; Beck and Mahony 2018; Jacob and Ekins 2020).

The Sustainable Development Goals (SDGs) point to significant changes in the way social, technical and environmental systems are organized (United Nations 2019; United Nations 2023). The international community, supported by assessments of scientific evidence, has recognized the need for, increased urgency of, and difficulties associated with transformations of most human systems in the face of environmental challenges.

Global environmental assessment reports have provided various definitions of system transformations and related challenges (**Appendix 12.1**). Taken together, these underline important considerations for system transformation that include the importance of system-wide change beyond technologies. These considerations include the need for alignment of technological, economic and social change and for reconfigurations of practices, norms, values and laws. As well, they cover the need to reconfigure unsustainable systems and to jointly support more sustainable systems and address structural causes of unsustainability and injustice (United Nations Development Programme [UNDP], United Nations Office on Drugs and Crime and Office of the United Nations High Commissioner for Human Rights 2024).

Furthermore, there is increased recognition that implementing system transformations also requires transformations of governance and decision-making structures (United Nations 2023; IPBES 2024), such as support for customary Indigenous governance of living territories (IPBES 2024).

Thus, what "fundamental system transformation" means, what system transformations entail, how to support them, or how to track and evaluate progress, remain largely unaddressed. What is needed is a sharper, more resolute and more uncompromising assessment framework for understanding transformations, how they can be supported and how they can be evaluated. This chapter intends to begin addressing this gap.

Box 12.1: Calls for system transformations to address environmental challenges sanctioned by the international community

- "Business-as-usual will not deliver the Sustainable Development Goals by 2030 or even 2050, yet the Goals are the survival kit behind the transformation process that the planet needs. Global scenario projections reveal plausible future pathways where rapid progress can be made towards the Goals. Harnessing these opportunities will require an increased level of ambition, transformative policies, and an integrated approach to organize and coordinate efforts." (United Nations 2023, p. 39)

- "Rapid and far-reaching transitions across all sectors and systems are necessary to achieve deep and sustained emissions reductions and secure a liveable and sustainable future for all. These system transitions involve a significant upscaling of a wide portfolio of mitigation and adaptation options." (IPCC 2023a, p. 28).

- "Goals for conserving and sustainably using nature and achieving sustainability cannot be met by current trajectories, and goals for 2030 and beyond may only be achieved through transformative changes across economic, social, political and technological factors" (IPBES 2019, p. 18).

- "The world has a huge challenge ahead of it to move net zero by 2050 from a narrow possibility to a practical reality. Global carbon dioxide emissions are already rebounding sharply as economies recover from last year's pandemic-induced shock. It is past time for governments to act, and decisively to accelerate the clean energy transformation. As this report shows, we at the IEA are fully committed to leading those efforts." (IEA 2021, p. 4).

Credit: tampatra/Envato

- "Current trajectories are fundamentally unsustainable; these trajectories are interconnected and linked to our main systems of production and consumption; and time is running out to come up with credible responses to bend the trend." (EEA 2019, p. 7).

- "The SDGs set out a vision for transformed societies that are prosperous, peaceful, meet the needs of all people, and protect the planet. There are many goals which the Asia Pacific region is far from achieving, and a transformation in focus and approach will be needed if we are to attain them." (United Nations Economic and Social Commission for Asia and the Pacific [ESCAP], Asian Development Bank [ADB] and the United Nations Development Programme [UNDP] 2018, p. 50)

12.3 Scientific perspectives for system transformations

A variety of scientific perspectives[1] is needed to address sustainability challenges and required system transformations (Turnheim et al. 2015; EEA 2017; Patterson et al. 2017; Loorbach, Frantzekaski and Avelino 2017; Cherp et al. 2018; Clark and Harley 2020). While there are many other perspectives, this chapter focuses on three relevant social science literatures engaging directly with system transformations and their governance in the context of environmental and societal challenges [2]:

- Socioecological transformations to sustainability
- Sociotechnical transitions to sustainability
  Socioeconomic transformations

These perspectives differ in terms of how system boundaries are drawn, how dynamics of transformations are represented, how future transformations are envisioned, and their lessons for governance. Taken together, these different perspectives can inform the challenges and governance of intentional system transformation, leading to improved resolution. The following section presents these perspectives one by one, while Section 12.5 distils them to derive general principles for system transformation and illustrate their applicability within the levers structure.

12.3.1 Socioecological transformations

Socioecological perspectives focus on the dynamic relation between human systems and natural systems. They represent socioecological systems as complex adaptive systems embedded in the biosphere (Folke et al. 2016). They include systems that humans fundamentally depend on for survival, like food systems (Ericksen 2008), but can also be extended to urban systems or cities that involve complex patterns of interaction between human and natural features, for example, ecosystem services, like water, green spaces, and coasts or wetlands (Elmqvist et al. 2018).

Socioecological transformations are rooted in resilience thinking that understands systems as constantly in a dynamic flow of revolting, then reorganizing and exploiting after the crisis, but also remembering, conserving and releasing that happens across scales (Rocha, Lanyon and Peterson 2022; Gunderson and Holling 2002). This perspective provides a meaningful way to think about change as being connected to different subsystems and over space and time. This is useful for helping us to understand the spillover effects of telecoupled systems – those systems that influence each other even if they do not seem to be directly connected (Liu et al. 2018). The key emphasis of this perspective is the fundamental essence of the biosphere, within which all social, economic and technological activities can take place and, related to this, that any deliberate intervention into a complex system can have unintended consequences (**Box 12.2**).

Resilience thinking shows that in the face of pressures, resilient systems are either persistent, adaptive or transformative. Adaptability is referred to as the capacity of people in a socioecological system to build resilience through collective action, whereas transformability is the capacity of people to create a fundamentally new social-ecological system when ecological, political, social, or economic conditions make the existing system untenable (Walker et al. 2004). Over the years, the term transformability has

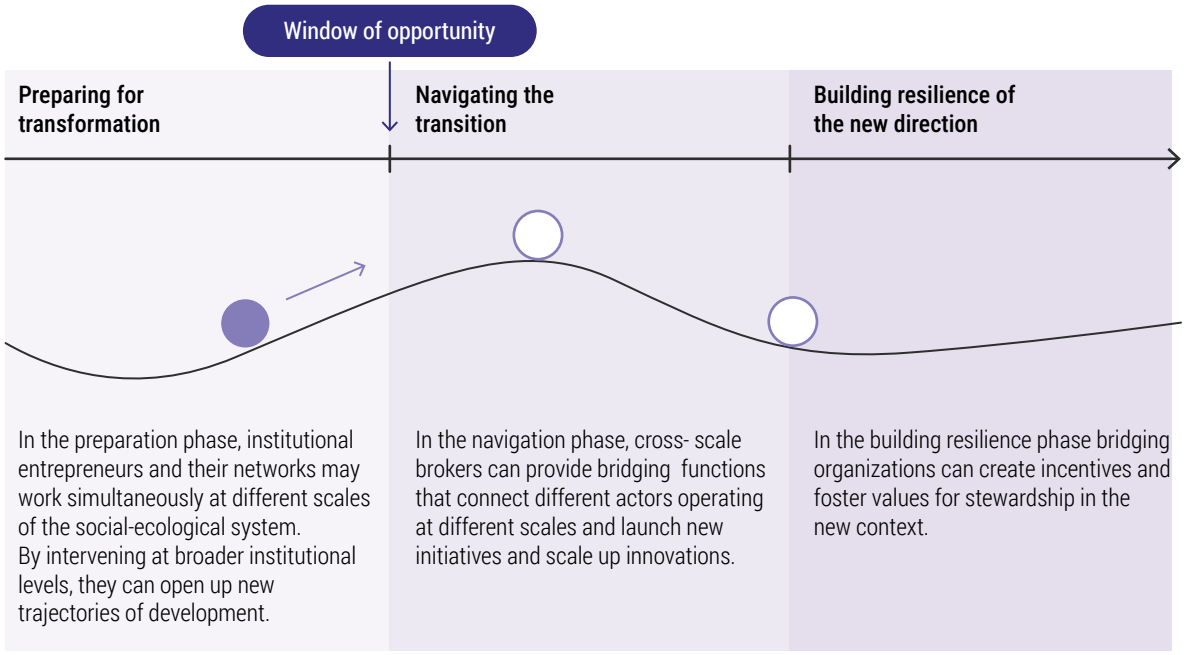
Box 12.2: Examples of unintended consequences of environmental interventions in complex systems

Examples include conservation efforts in the Amazon, which have led to increased deforestation in surrounding areas, or the regulation of fisheries in one region of the world resulting in increased exploitation in another less stringently regulated region (Pereira et al. 2024).

1 While this section exclusively builds on three scientific perspectives from which to distill established and consensual knowledge on system transformations, this chapter and the entire GEO-7 is receptive to a plurality of relevant forms of knowledge, including Indigenous and Local Knowledge as essential ways of seeing and being that can and must inform system transformations. The principles for system transformations laid out in section 12.4 have been influenced by such a pluralist view.

2 These literatures have been selected because they take 'system transformation' as their primary object of enquiry and because far-ranging consensus exists concerning their core contributions. The European Environment Agency has recognized the policy-relevance of learning from these perspectives to inform transformations towards sustainability (EEA 2017).

been expanded to refer to "transformations towards sustainability" as fundamental changes in structural, functional, relational, and cognitive aspects of socioecological systems that lead to new patterns of interactions and outcomes (de Haan and Rotmans 2011; Hackman and St. Clair 2012; O'Brien 2012; Feola 2015; Patterson et al. 2017), namely for a better inclusion of considerations of power. There is a growing literature on how equity, justice and acknowledging unequal power dynamics are central to navigating transformations (Blythe et al. 2018; Pereira et al. 2019).



There are three phases to how socioecological transformations are enabled, although these can also be iterative (Olsson, Folke and Hahn 2004; Folke et al. 2010) (**Figure 12.1**):

- **Phase 1:** In the preparation phase, institutional entrepreneurs and their networks may work simultaneously at different scales of the socioecological system. By intervening at broader institutional levels, they can open up new trajectories of development.
- **Phase 2:** In the navigation phase, cross-scale brokers can provide bridging functions that connect different actors operating at different scales to launch new initiatives and scale up innovations.
- **Phase 3:** In the building resilience phase, bridging organizations can create incentives and foster values for stewardship in the new context.

When a system is in limbo between the existing, dominant state and a new alternative state, hybrid approaches to transformative and transitional justice are essential for moving forward. These approaches include addressing backlash dynamics as a relapse back to the former unsustainable system, strengthening the capacities needed to navigate cross-scale dynamics of conflict, and responding to additional shocks, crises and disturbances beyond the primary conflicts (Olsson and Moore 2024).

Given the current planetary ecological pressures, transformation towards new systems has become a necessity as current conditions make the existing system untenable (Rockström et al. 2023). This requires a new trajectory or pathway away from business as usual (Walker et al. 2004; Folke et al. 2010; Westley et al. 2011; Frantzeskaki, Loorbach and Meadowcroft 2012; Pereira et al. 2018). However, the question of where to transform towards remains, given the complex and messy reality of systems and the diverse values that underpin what is deemed preferable, and who makes these decisions (Pereira et al. 2020; Pereira et al. 2023). There is increasing agreement about which options are not preferable because they fall outside a safe and just operating space (Rockström et al. 2023) or do not have

Figure 12.1: Three phases of socio-ecological transformations

Source: Stockholm Resilience Center (2016)

a sustainable human-nature relationship at their core (IPBES 2016; Pereira et al. 2020). This is why co-created visions are critical, as these can inspire transformative futures from which action can be developed (Pereira et al. 2021). Acknowledging the plurality of potentially preferable futures based on diverse value systems has implications for the orientation of transformative interventions (Pereira et al. 2023; Villasante et al. 2022; Chibwe et al. 2024). In addition, the plurality of ontologies and values in sustainability future-making (Harmáčková et al. 2023) implies making space in decision-making for subaltern perspectives, including those of Indigenous Peoples, as a challenge to the dominant formations (Scoones et al. 2020), such as colonial modernities that continue to reproduce and intensify social-ecological damage (Arora and Stirling 2023).

Enabling socioecological transformations requires systemic shifts in mental models and paradigms, and changes in institutions, management routines and resource flows (Meadows 1999; Westley 2013). It is also crucial to recognize the role of human agency and the evolving or expanding roles of the diverse types of actors driving these transformations (Westley et al. 2013). However, there remains a question of how top-down and bottom-up interventions for transformative change interact and whether bottom-up initiatives have sufficient capacity to shift dominant power dynamics (Scoones et al. 2020). A recognition of the need for transformations of structures, systems and individuals is growing, but research gaps remain on how to enable these changes equitably (Pereira et al. 2020). One such pathway is through the strengthening of local initiatives that could lead to more sustainable and equitable futures (Bennett et al. 2016; Pereira et al. 2018). The transformative potential of bottom-up initiatives has been outlined by Tuckey et al. (2023) and how to scale or amplify their impact has been demonstrated by Lam et al. (2020) (**Box 12.3**).

Box 12.3: Examples of scaling in food systems

Specific examples within the food system have tracked niche initiatives that have grown over time in Cape Town, Stockholm and Spain, understanding some of the institutional barriers that they faced and how leveraging networks and building coalitions helped to overcome some of these (Guerrero Lara et al. 2019; Lam et al. 2022; Sellberg et al. 2020).

At the same time, several capacities for transformation have been brought to the fore, including the need for imaginative capacity to envision the transformations required (Moore and Milkoreit 2020). Unpacking agency for enabling transformation across individual to organizational levels is crucial to understand in diverse contexts, as this has implications for the actions that can be undertaken (Charli-Joseph et al. 2018).

12.3.2 Sociotechnical transitions

The sociotechnical transitions literature (Kemp, Schot and Hoogma 1998; Markard, Raven and Truffer 2012; Köhler et al. 2019) focuses on the long-term, fundamental transformation of sociotechnical systems, such as energy, mobility and agrifood, in concrete settings. Rather than focusing on a particular technology or innovation, for example, cell phones, a sociotechnical perspective points to the larger systems that enable the production and consumption of goods and services tied to the provision of societal functions, such as food, heat, power, shelter and health.

Sociotechnical systems are configurations of heterogeneous entities (Geels and Turnheim 2022):

- material elements as artefacts, infrastructures, flows
- relational elements as actors, networks
- institutional elements as regulations, norms, values

The development of sociotechnical configurations is a coevolutionary process in which technologies, infrastructures, supply chains, user preferences, markets, policies and cultural meanings mutually shape each other over extended periods (Geels 2002; Geels 2004). This mutual shaping produces alignment between technical features and institutional features. As a result, once established, sociotechnical configurations are dynamically stable and inherently resistant to change.

The inertia of established sociotechnical systems is structural and enacted (Turnheim 2023) mainly due to:

- structural lock-ins, such as sunk investments, increasing returns to scale, standardization, cognitive routines, asymmetric access to rule-setting, strategic alliances, and normalized

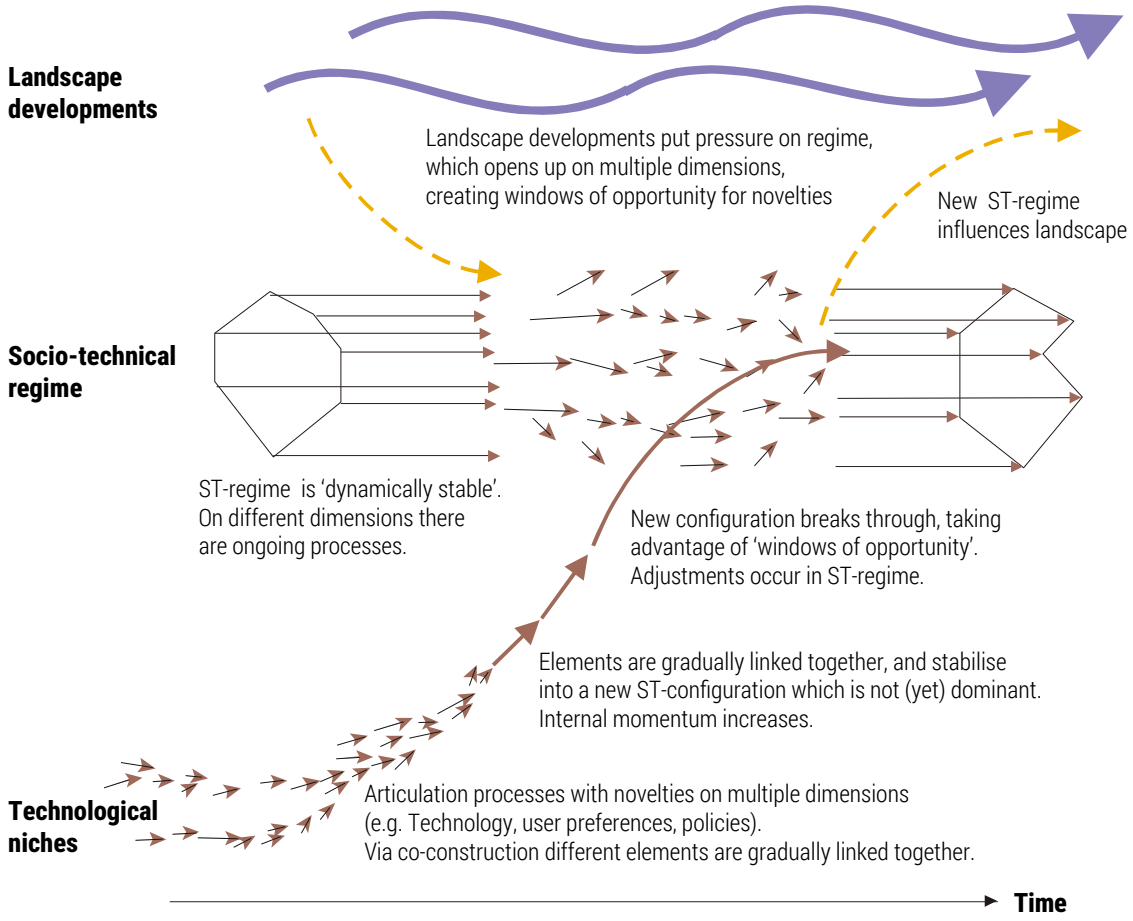
ideologies (Nelson and Winter 1982; Arthur 1989; Pierson 2000; Unruh 2002; Klitkou et al. 2015) that tend to favour existing structures, and actors who make it more difficult for alternative configurations to emerge

- active resistance strategies, notably by incumbent actors – industry, policy, and other actors whose power, resources and vested interests are tied to these systems (Stirling 2019; Turnheim and Sovacool 2020) – who invest in maintenance and improvement activities, reproduce advantageous regime rules, and defend current arrangements when new problems arise.

These mechanisms make sociotechnical transitions rare and difficult. Incremental adjustments and marginal improvements that tend to preserve established configurations are more likely to occur than radical and fundamental transformative change (**Box 12.4**). Even when change happens, it tends to be incremental unless particular conditions are met. Furthermore, sustainability transitions, which are a particular kind of sociotechnical transition guided by new objectives, such as sustainability, present a dual challenge of fundamental changes in sociotechnical configurations, as well as fundamental changes in prevailing performance criteria (Kemp and van Lente 2011).

Given system lock-ins, sociotechnical transitions involve substantially new ways of doing things – radical innovation – and new ways of putting things together – reconfiguration.

The multidimensional perspective on sociotechnical transitions (Kemp, Schot and Hoogma 1998; Geels 2002; Geels 2004; Geels and Turnheim 2022) further suggests that transitions can be depicted as involving changes within and across three



Box 12.4: Examples of marginal improvement in sociotechnical transitions

Examples of marginal improvement pathways include, for instance, end-of-pipe solutions such as the mandatory installation of catalytic converters in petrol cars to deal with local air pollution problems from the 1970s, or the diffusion of electric vehicles as a means to decarbonize automobility from the 2000s without fundamentally addressing personal mobility patterns. By contrast, a more fundamental system transformation would involve, for instance, a very substantial decline of car-based mobility along with the deployment of slow mobility modes, which would inevitably transform the topology of urbanization (Banister et al. 2011; Wells 2023).

Figure 12.2: A dynamic multi-level perspective on system innovations

Source: Geels (2002b)

levels of structuring social and technical activities, namely, niches, systems and landscapes. Within this space, characterized by structuration and temporal dimensions, any transition essentially involves the interaction of three processes: radical innovation, generalization and destabilization (**Figure 12.2**).

Radical innovations are developed in niches, that is, relatively protected spaces shielded from prevailing selection pressures (Smith and Raven 2012), by alternative innovation communities and often in response to new problems or new technical promises.

Radical innovations are initially considered hopeful monstrosities that do not fully work; they are initially full of defects, prone to failure and ill-adapted to existing technical capacities or institutional requirements. But they are simultaneously attached to significant expectations (Truffer 2008; van Lente 2012; Konrad and Böhle 2019) concerning their economic or technical development potential, or the promise to address long-standing problems (**Box 12.5**). Most innovations, whether social, technological, organizational or policy, remain stuck at the niche level.

Box 12.5: Examples of radical innovations

Solar photovoltaic technology is an example of a successful radical innovation, which initially was so costly and inefficient that significant hope and imagination were required to envision its mass deployment for civil purposes.

At its beginnings in the late 1800s, the petrol car was far from an inevitable success: it was considered dangerous and costly, had a very limited range and was hindered by the lack of paved roads or repair networks.

Box 12.6: Examples of generalization and diffusion in socio-technical transitions

The generalization of renewable energy technologies as a legitimate, cost-efficient and reliable energy source required scaling and improvements enabled by ambitious incentive programmes, such as Energiewende, the German energy transition plan.

The generalization of conventional or high-input agriculture from the 1950s benefited from major development programmes such as the Green Revolution, supported by the promises of "food for all" legitimized by recurring food shortages and famines in the 1970s, as well as tight-knit networks of technical support prescriptors.

The generalization of innovations involves the development of innovations beyond their initial niche application, through widespread deployment and use. This generalization is not merely the diffusion of standardized products or services through markets (Rogers 1995). It also involves the mutual shaping of innovation and its uses (Leonard-Barton 1988), the establishment of dominant designs, processes of scaling, institutionalization, learning, and network development. It may lead to the displacement of existing systems, their incorporation, or simply coexistence alongside existing systems (Berkhout 2006; Raven et al. 2016; Avelino 2017) (**Box 12.6**).

The destabilization of existing systems is a process by which established sociotechnical configurations "become exposed to challenges significant enough to threaten their continued existence and their 'normal' functioning" (Turnheim 2023, p. 45). This destabilization can lead to full decline, partial decline, reconfiguration, or even system improvement, when challenges are addressed. Destabilization contexts involve combinations of exogenous pressures, for example, landscape changes such as urbanization trends, war and conflict, and environmental problems, and endogenous pressures, such as technical difficulties or accidents, lack of resources, mismanagement, and disbanding of alliances. The intentional destabilization of sociotechnical systems is commonly referred to as phase-out (**Box 12.7**).

Box 12.7: Examples of phase-out

Phase-out has been applied to specific substances such as DDT, asbestos, mercury, class A drugs, or leaded petroleum, to practices such as private animal slaughter, inner-city automobile use, or indoor smoking and, to a lesser extent, to entire systems such as dismantling of tramways, household coal delivery, or whaling.

Credit: rawf8/Envato

12.3.3 Socioeconomic transformations

The literature on socioeconomic transformations relates to the long-term transformation of society and economy. It focuses on the interrelations between economic systems and human development, often in historical perspective. There are different perspectives on socioeconomic transformations, owing to contributions from:

- academic traditions of political economy such as Marx, Polanyi or Keynes, historical sociology such as Tilly or Schor, and institutional theory such as Streeck or Thelen

- advocacy traditions from different organized public sources, including multilateral organizations such as the International Monetary Fund, Organisation for Economic Co-operation and Development, or World Bank and civil society in the form of trade unions, workers' movements, or the post-growth movement, among many others.

Major socioeconomic transformations have influenced the development of national economies and related patterns of lock-in to resources and industries. Structural changes in productive sectors, such as the shift from primarily agricultural to capital-intensive industrialized economies, for instance, are significant socioeconomic transformations that fundamentally alter the nature of economic activities, job and employment prospects, opportunities for capital accumulation, and trade opportunities. In different parts of the world, past socioeconomic trajectories determine current patterns of dependence on resources and industry, for example, oil-rich or mining-dependent countries (Bridge 2008; Adams et al. 2019; Pérez and Claveria 2020), as well as related social and environmental effects, both positive and negative.

Socioeconomic transformations depend on favourable institutional and policy conditions (Chapter 14) that 1) enable and support the reconfiguration of economic systems; 2) modulate the outcomes of the reconfiguration of economic systems, both negative and positive; or 3) may need to be radically transformed themselves. Socioeconomic transformations combine the opportunities offered by new modes of production with the associated technoeconomic paradigms of routines, values and beliefs conditioning economic activity (Freeman and Louça 2001). Perez (2003) identifies five significant surges of technoeconomic development in world history that follow similar overarching patterns, from installation to deployment. Organizational and institutional adjustment to new modes of production lead to new technoeconomic paradigms that become "the shared, established and unquestioned 'common sense' both in the economy and in the socio-institutional framework creating a clearly biased context in favour of the trajectories of the technologies of the revolution and their use across the economy" (Perez 2010 p. 199). Major socioeconomic transformations may require the transformation of institutional and policy conditions themselves.

There are major disparities in socioeconomic transformation patterns. Within the globalization of economic development and trade, socioeconomic transformations are not uniform but follow place-dependent patterns (Boschma et al. 2017), specifically in relation to local natural resource endowments or restrictions, as well as past forms of economic and institutional development (Fritz and Koch 2016).

Different patterns of socioeconomic development have:

- a significant effect on the wealth generated, for example, disparities between economies worldwide

- regional specialization, for example, specialization of productive industries and related flows of goods and services within global supply chains

- the supportive institutional framework, for example, wealth redistribution, welfare systems and safety nets, mitigation of health and environmental impacts

As a general rule, advanced economies have transformed their economic or sectoral structure towards greater variety, more services and less agriculture, while low-income countries remain primarily dependent on the agricultural sector for employment and economic output.

Socioeconomic transformations, while supporting the development of new forms of wealth, value and opportunities, also generate unsettling social and economic outcomes that require active efforts to avoid, reduce or regulate them. The adverse outcomes that can be associated with major socioeconomic changes are a

central theme of scholarship and institutional work on socioeconomic development:

- concentration of structural inequalities – ownership, power, privilege, access – resulting from various forms of private accumulation of means of production – capital, skills – typical of capitalist economies (Marx 1946; Kuznets 1955; Swilling 2020), which runs counter to the possibilities of equal and just societies

- commodification and marketization of everything – nature, skills, things – seen as a historical movement of economic development leading to inherent contradictions (Polanyi 1944), and calling for "re-embedding" markets in the control of democratic institutions and state organization, as these provide the only hopeful prospects for responsibility within liberal economic systems and their primacy of the individual and their freedom

- misplaced indications of value, which tend to condition the performance of social and political interventions to those maximizing monetary economic growth over alternative forms of value and human development, such as well-being, rights, social justice and poverty alleviation (Sen 1983; Sen 2002).

Patterns of change

Socioeconomic transformations involve different kinds of dynamics and patterns:

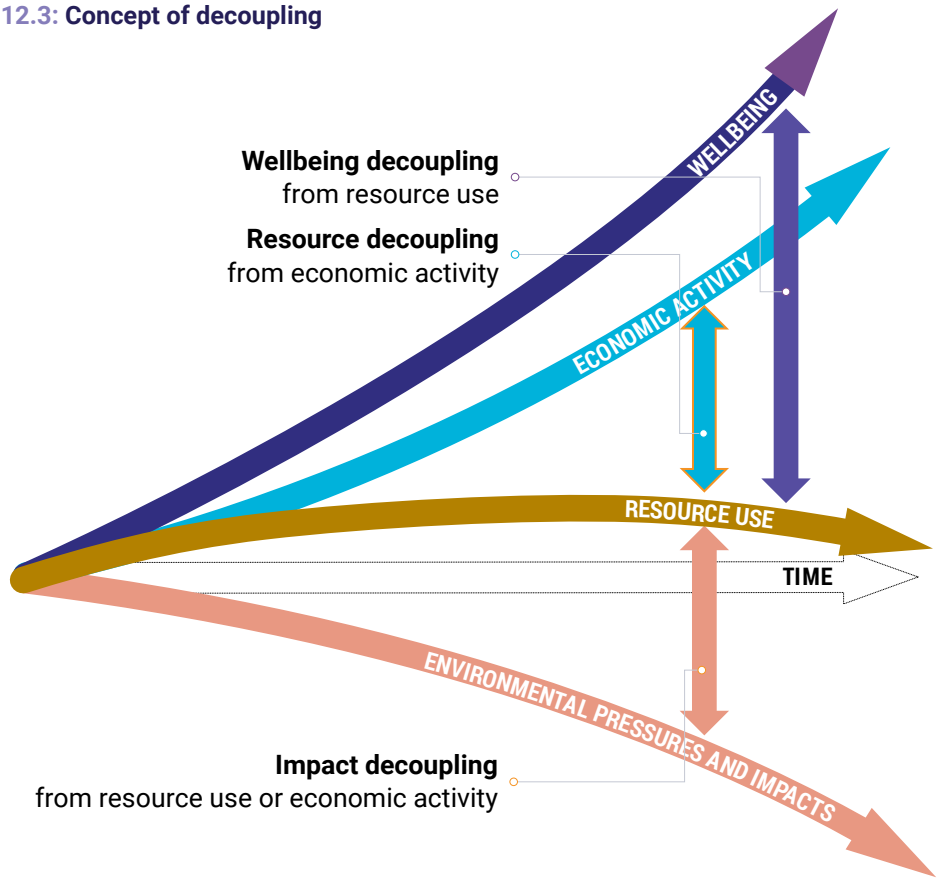
- structural patterns – for example, capital accumulation, deepening inequalities, structural sectoral shifts – calling for support or correction mechanisms

- cyclical patterns – for example, technological revolutions, business cycles, investment patterns – offer cues for regularities that need to be attended to or anticipated

- counter-movements and social contestation – for example, around particular social or environmental issues – can lead to changes in institutional frame conditions for economic development that may follow more or less abrupt patterns and lead to more or less discontinuous outcomes (Streeck and Thelen 2005)

- socioeconomic transformations are largely influenced by macrotrends such as urbanization patterns or global political economy and macrodisruptions such as wars, conflicts, and other crises.

Relation to social and environmental sustainability



An important starting point is that socioeconomic transformation is not necessarily aligned with environmental or other progressive agendas, and that in some cases, there are deep tensions between economic development and social and environmental goals. For instance, while digitalization has become an important driver of socioeconomic transformation of national economies and sectors, there is no assurance that it will bring about environmental benefits and, in some cases, it may even contribute to greater environmental impacts. Aligning socioeconomic transformations with environmental goals requires dedicated institutions and possibly reorienting prevailing criteria for evaluating economic activity in line with shifts in and related decoupling (**Figure 12.3**).. Several alternative orientations can provide direction for socioeconomic transformations, including the following.

- A greening perspective on socioeconomic transformation suggests that environmental goals can be addressed within current economic systems through reforms and ecological modernization (Tienhaara 2014).

- A just transitions perspective focused on improving social justice, worker rights and access to decent employment conditions (Swilling 2020). Concerning environmental problems, these perspectives emphasize the need for anticipating and planning for training and reskilling needs, notably in areas and sectors with high dependency and vulnerability to activities deemed less desirable in favour of activities that may hold greater promises of development.

- Well-being perspectives suggest that attending to planetary and human limits, and economic policies requires more priority on objectives related to basic human needs (Sen 2002). Economic development should therefore be linked to more concrete provision objectives, for example, "providing high-quality public services,

Figure 12.3: **Concept of decoupling**

Source: Revised from IRP (2019b)

strengthening democracy, establishing greater income equality, ensuring universal access to electricity and clean fuels, improving trade and transport infrastructure, increasing public health coverage, minimizing extractive industries and abandoning economic growth beyond moderate levels of affluence" (Vogel et al. 2021, p. 13). These perspectives point to the relevance of reconfiguring economic systems towards more collective purposes, both social and economic, notably in terms of reducing material and energy waste, stronger public services, a priority for green employment and production, and making more space for care activities (Hickel et al. 2022).

- Post-growth perspectives point to the inherent contradictions of using metrics of economic growth, such as gross domestic product (GDP), as a prime indicator of societal development (Hickel et al. 2025; Kallis et al. 2018; International Panel of Social Progress 2018). Instead, they suggest that decoupling environmental and social effects from economic activity requires fundamentally renewed markers of societal development and social progress (UNEP 2011), which may entail breaking with the expansionary dynamics of capitalism and its inherited power relations in favour of collective, self-limitation and no-harm principles (Brand et al. 2021).

- Applying a pluriversal perspective, "a world where many worlds fit" (Escobar 2021), offers a pathway where environmental and social justice is achieved through transformative processes. A pluriversal approach supports shifts away from domination and control traditions towards lifeways that allow for multiple ways of knowing and being to guide how societies are organized, for example ways based on ethics of care and reciprocity (Escobar 2021). Such an approach provides space for Indigenous Peoples' ways of knowing and being in future decision-making and societal organization. Instead of separate human and nature systems, this envisions interdependent, entangled assemblages of humans and non-humans co-creating life.

More broadly, these socioeconomic perspectives suggest that there is a fundamental tension between equity and efficiency as foundations for economic systems, and that environmental and societal challenges provide a new impetus and various opportunities to address this.

12.3.4 Synthesis of the perspectives on system transformations

The three perspectives discussed in the previous sections offer consistent and complementary insights for the analysis of change dynamics and the scope for governance (**Table 12.1**). By bringing particular sets of relations in their system definition to the fore, each perspective sheds light on essential features and constraints of human systems and related development trajectories. The three perspectives understand system transformation as requiring: 1) a significant departure from powerful stabilizing mechanisms – lock-in, mutual shaping, persistence; and 2) activation of complex change mechanisms. They also highlight structural tensions and adverse outcomes, such as vulnerabilities, negative externalities, power imbalances, structural injustices and contradictions, at the heart of certain transformation paths, hence suggesting that clear orientations of change are necessary to ensure desirable outcomes.

Table 12.1: Juxtaposing three perspectives on system transformation

	System focus	Prevailing dynamics of change	Orientations of change	Lessons for governance and sustainability
Socioecological	Interlinkage between society and ecology	• System vulnerability • System resilience: persistence, adaptation or transformation patterns	• Ecological thresholds and boundaries • Consideration of plural values • Complexity of transformation	• Enhancing transformative capacity • Co-created visions combining practical, political and personal dimensions of change
Sociotechnical	Mutual shaping of technology and society	• Stabilizing mechanisms: lock-ins, actor resistance • Change mechanisms: • innovation, destabilization	• Overcoming lock-ins requires radical innovation: technical or institutional • Normative goals influence the direction of change • Radical change is political	• Phasing in and preserving sustainable entities • Phasing out and avoiding unsustainable entities • Navigating and anticipating inherent uncertainties
Socioeconomic	Mutual shaping of economy and institutions	Dual movement: • Wealth creation • Negative outcomes: injustice, externalities	• Economies can be reformed or reconfigured • Alternative objectives can be legitimate for economies, for example, justice, greening, well-being, post-growth	• Altering institutional conditions for economic development • Avoid, reduce and regulate negative externalities

The governance of system transformations is an inherently political matter involving difficult decisions mediated by societal and value choices, for which technocratic resolution is unlikely to be the most suitable mode of governance.

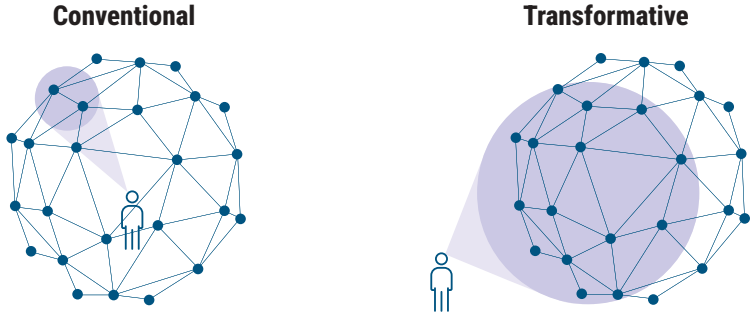
Combined, these three perspectives offer lessons for the governance of system transformations. Section 12.4 translates these lessons into a set of six principles for system transformations.

12.4 Six fundamental principles for system transformations

As discussed in the previous section, because system transformations are inherently complex and value-laden processes that generate significant challenges for contemporary governance structures, a consistent evidence-based framework for understanding dynamics and governing change in desired directions is necessary for transformation to take place.

This section distils this knowledge into a set of six key principles for system transformations, pointing to essential processes, mechanisms, and normative considerations that all need to be addressed to craft feasible transformation pathways and maximize the likelihood of their implementation. These six key principles also work as a list of criteria and a checklist for system transformations. Chapter 13 presents a methodology for evaluating and monitoring system transformations that builds on the following principles.

12.4.1 System configurations and lock-ins



Principle 1: The governance of system transformations needs to be explicitly targeted at whole systems and address underlying sources of lock-in related to current system configurations (**Figure 12.4**).

System transformations to address global environmental crises involve jointly addressing two key challenges (Kemp and van Lente 2011): pervasive adverse effects, and systemic lock-ins. Appropriate representations of these system configurations and related sources of lock-ins (Klitkou et al. 2015; Goldstein et al. 2023) are essential preliminary steps to appreciate the obstacles, possibilities and constraints relating to system transformations.

Actionable system representations show how interlinkages between entities in different dimensions point both to sources of stability and opportunities for transformative change. Ecosystems and societal systems are "wicked" systems that combine high degrees of complexity – they have emergent features of self-organization – and complicatedness, that is, they have high levels of structure resulting from top-down organization (Andersson, Törnberg and Törnberg 2014). For these reasons, representing such systems and their functioning is challenging because they escape formal reduction efforts. Different perspectives emphasize different entities and sets of relations (EEA 2017; Clark and Harley 2020), and hence offer complementary insights for action (**Table 12.1**):

- socioecological perspectives focus on the interactions of environmental components – the local natural environment, climate and nature-related factors – and human components – local human communities, their cultural practices and institutions – and position intentional transformative action within nested spheres of the practical, political and personal (O'Brien 2018)

Figure 12.4: Transformation principle 1: Target policies at whole systems

- sociotechnical perspectives focus on the mutual shaping of technology and society, representing systems as semi-coherent bundles of technology, policy, industry, markets/users, science and culture (Geels 2002; Geels 2004; Marletto et al. 2016; Geels and Turnheim 2022)

- socioeconomic perspectives focus on the interaction of economic and social systems, and the scope for institutional frameworks and responses to structure and modulate these systems

Adequate system representations need to account for the routine functioning of existing systems and underlying configurations-that is, the linkages between heterogeneous elements-to highlight the primary sources of systemic lock-ins and their main challenges. Focusing on whole systems rather than addressing individual elements in isolation is essential; not doing so is likely to lead to incremental or substitution patterns with limited transformative effect. Additionally, scholars suggest that defining systems is a subjective process, hence it is important to consider how a system and its boundaries are framed and by whom (Leventon, Abson and Lang 2021). This further highlights the importance and democratic relevance of jointly mobilizing a plurality of perspectives.

To be effective, system transformations require a combination of actions targeted:

- at entire systems, or linkages between multiple elements of systems

- across social and ecological dimensions, or the underpinning philosophies and values, understanding that a functioning biosphere is needed for all societal transformation

- at different levels, ranging from deep society-wide actions, for example, transforming financial incentive structures, to more targeted actions, for example, sectoral policy and local actions

- at radically altering established configurations, which can be understood as actions seeking to stretch the limits of what is technically possible and actions transforming existing institutional frameworks – the sets of rules at play.

12.4.2 Some things in, some things out

Principle 2: The governance of system transformations needs to jointly address opportunities and challenges in new and existing systems, through explicit choices resolving contradictions between what must be developed, phased out, preserved and avoided.

Desirability, including the diversity of preferences, is a central dimension for orienting choices in system transformations. As new system configurations emerge, value-laden decisions need to be made regarding what novelty is introduced, what is preserved what is avoided, and what is phased out.

Emergence and phase-out

Regardless of their specific pattern, system transformations involve the emergence of new systems and features, as well as the destabilization and possible decline of existing systems and features. Contrary to common representations, for example, in technoeconomic modelling, transformations rarely involve like-to-like or synchronous substitutions of one system for another or purely win-win choices. Instead, they involve reconfiguration patterns determined by the articulation of emergence and destabilization processes (Schot and Geels 2007; Kivimaa and Kern 2016; Geels and Turnheim 2022). Furthermore, substitutional changes are rarely transformative, because they maintain the stability of most systems, without significant potential for empowerment. Too often, transformative action focuses on support for new, desirable things but neglects the importance and difficulties of abandoning and preventing harmful practices and systems. Consequently, it is essential that emergence and destabilization are *jointly* considered as priorities for interventions.

Environmental goals as desirability horizons

The current configuration of societal systems, such as energy, food, mobility and health, is a product of their historical path-dependent development in the achievement of 20th century performance objectives, such as the corresponding access to energy, higher yields, convenient mobility, and access to health. While these objectives remain important, sustainability objectives provide new and commonly accepted goals that can support major reorientations of societal systems. Reorienting system performance towards sustainability requires fundamentally transforming its constitutive

elements towards the achievement of new functions and possibly the abandonment of prior functions. Capacities to envision sustainability futures, including representation of Indigenous and relational philosophies that conceptualize relations of care and reciprocity of care as central to the regeneration of webs of life, are central to sustainability transformations; these focus on relations rather than on components of systems.

Competing norms and objectives

Transformations and transformation goals can be more or less desirable. Transformation concerns not only the deliberate reconfiguration of existing systems towards new performance objectives, which themselves need to be contested as there are plural conceptualizations of sustainability. A number of important transformations, such as digital transformation, deep-sea mining, and the dismantling of the welfare state, are currently ongoing and not necessarily oriented towards sustainability objectives in any way. In such cases, addressing environmental goals may involve avoiding these undesirable dynamics, or reorienting them towards more desirable goals.

Figure 12.5 specifies four broad types of orientations for action that need to be considered jointly in the governance of system transformation:

- Developing new desirable systems
- Preserving existing desirable systems
- Avoiding new undesirable systems
- Phasing out existing undesirable systems

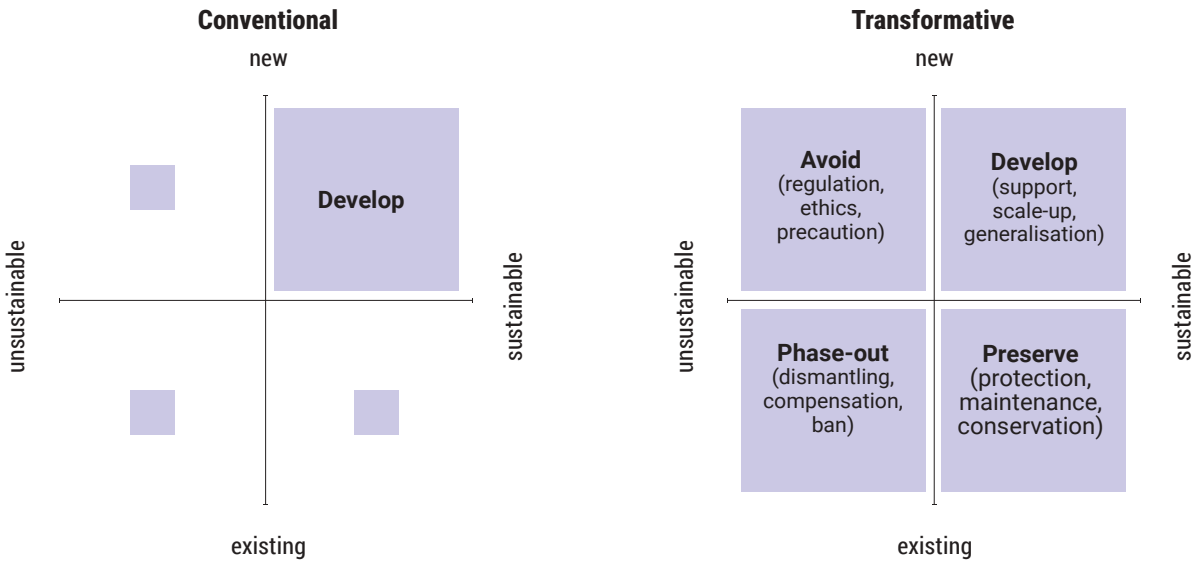
It is essential that any strategy aiming for system transformation considers actions within each of these orientations and addresses potential conflicts or inconsistencies. Each of these orientations implies particular portfolios of action, concerned actors, and types of analysis to anticipate and evaluate the resulting change.

12.4.3 Temporalities and non-linearities

Principle 3: The governance of system transformations needs to articulate near- and long-term solutions in sequences of action enabling constructive linkages between multiple temporalities and accounting for non-linear dynamics (**Figure 12.6**).

System transformations are processes that connect past, present and future. The futures envisioned today – in scenarios, promises or expectations – are conditioned by what is deemed feasible, desirable or supported in the present. Legacies from the past determine present realities and considerably narrow future development options. Knowledge of past crises and transformations, however, also points to the possibility under certain conditions of enacting radical changes beyond imagination or beyond what is currently deemed possible (Schot 2016). Historical precedents of system transformations can be recalled in the present as they provide useful analogues, narratives

Figure 12.5: Transformation principle 2: Combine innovation with phase-out



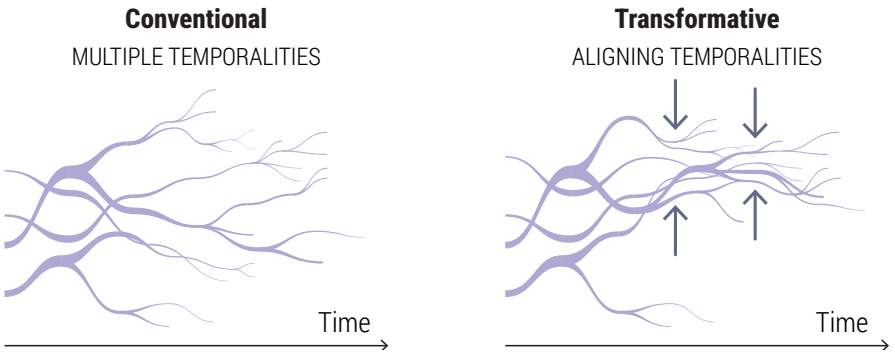


Figure 12.6: Transformation principle 3: Align present prospects with future perspectives

and lessons to inspire change (Samman 2015), reminding us that past transformations were deemed impossible until they became a reality (Dupuy 2002).

System transformations are conditioned by multiple temporalities (**Figure 12.6**). Societal systems and their change horizons are configured by mechanisms at different timescales (Braudel 1970; Sewell Jr 2005), including:

- long-term – infrastructures, scientific and technoeconomic paradigms, macroeconomic cycles, beliefs and values (Braudel 1970; Freeman and Louça 2001; Perez 2010)
- medium-term – strategic business plans, innovation cycles, electoral cycles and issue lifecycles
- short-term – political decisions, policy action, investment decisions, economic transactions, swings of public opinion, events and accidents.

The multiple temporalities of change are rarely aligned and are often dissonant (Haarstad and Rusten 2015). System transformations do not follow a single master process, but sequences of change that articulate multiple causal patterns (Aminzade 1992). Different cultures may have different understandings of time, including circular rather than linear notions, which need to be recognized when envisioning sustainability transformation pathways (Terry et al. 2024).

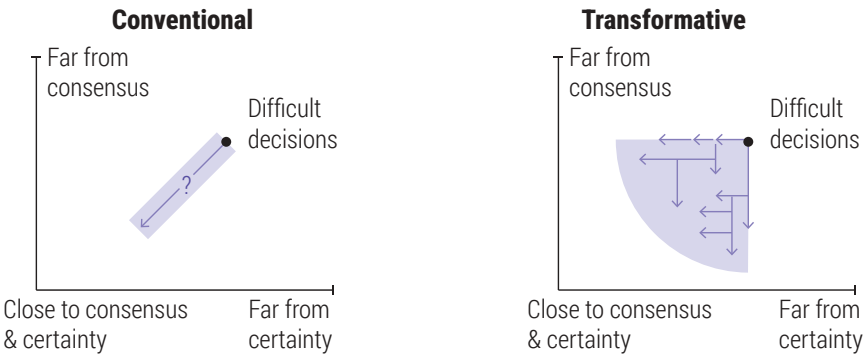
System transformation becomes more likely when change dynamics are aligned across temporalities. Opportunities for alignment with sociopolitical dynamics include addressing negative feedback, for example, backlashes and resistance by key actors, competing or divergent policy objectives, capture of transformation benefits by vested interests, and anticipation of legitimate losses, and reinforcing positive feedback by generating cumulative patterns of change, for example, planning and control, long-term programmes, lifting sources of divergent interests, and strengthening change coalitions (Lockwood 2015). The articulation of shared visions, promises and expectations is critical to generating greater directional coherence by aligning the interests of the actor constellations involved (Patterson et al. 2017; Roberts et al. 2018). Open deliberation about future options, envisioned transformation pathways and related challenging decisions is essential to generate greater societal involvement and buy-in, and hence to lift latent sources of resistance to change through legitimation processes.

Given that there is no single instrument that can trigger and sustain transformation on its own, governance interventions must combine multiple actions in a temporal sequence. Combinations of action need to target all relevant mechanisms and stages of transformation, including new system configurations such as emergence, acceleration and stabilization and existing, unsustainable system configurations such as destabilization, breakdown and phase-out (Kivimaa and Kern 2016 Fazey and Leicester 2022; Allen and Malekpour 2023). The temporal ordering of near-, mid- and long-term actions needs to not only seek cumulative amplification of change sequences in a given direction (Nilsson and Nykvist 2016), but also to identify critical hurdles and enabling conditions of change. For instance, infrastructure investments – with long lead times and planning constraints – are often critical enablers of further actions and practice changes. Shared transformation pathways and attention to their conditions of feasibility are essential (Turnheim and Nykvist 2019).

System transformations unfold at varying speeds and are exposed to non-linearities. The speed of transformation depends on the scale and scope of transformations (Grubler, Wilson and Nemet 2016), the types of solutions sought (Bento and Wilson 2016), the activation of positive and negative feedback mechanisms, and context-specific events and conditions that may accelerate or slow down change (Fouquet 2016; Sovacool 2016). The vagaries and non-linearity of long-term processes also call for openness and flexibility in the sequencing of transformative actions to provide adaptability to real-world contingencies (Cheng et al. 2015).

Crises and shocks have a strong influence on the possibilities of rapid transformation, both desirable and undesirable, but are inherently unpredictable. Shocks are abrupt, discontinuous and disruptive events with the potential to alter system context and conditions significantly. They can reorient transformation paths by interrupting promising change dynamics, triggering new development paths or accelerating existing ones. Shocks and crises include technical accidents, scandals and failures (Perrow 1997; Newig et al. 2019; Turnheim and Sovacool 2020), institutional events that may lead to regime collapse or revolutions, for example in the context of wars, internal unrest, or state and economic failures (Hay 1999; Streeck and Thelen 2005), as well as irreversible tipping points in social or ecological conditions enabling normal or resilient system functioning (Cumming and Peterson 2017; Lenton et al. 2020; Stammer et al. 2021). Preparedness for possible crises is critical to minimizing their impact and maximizing their transformative potential.

12.4.4 Uncertainty and anticipation



Principle 4: The governance of system transformations needs to be supported by new ways of dealing with uncertainties, anticipation and plural ways of knowing and being (**Figure 12.7**).

System transformations involve radical uncertainty and unpredictability (Andersson, Törnberg and Törnberg 2014) that inherently limit the possibilities of prediction, control and top-down planning (Hajer et al. 2015) of conventional governance styles.

Uncertainty and unpredictability are particularly important with respect to the following.

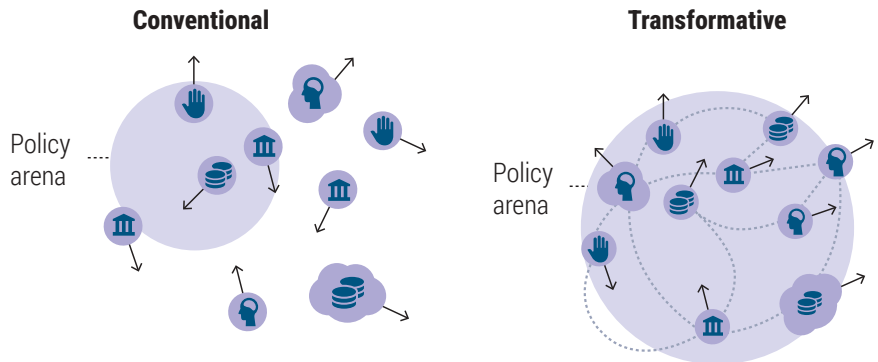
- Temporalities of change. How fast can new practices or systems be developed and deployed? How fast can harmful practices or systems be abandoned? System transformation processes most often do not follow linear development patterns, but instead are exposed to largely unpredictable detours, setbacks or even backlashes when particular pathways become unviable due to technical, acceptance or political challenges.
- Unforeseen concerns and risks. As new practices or systems are introduced in real-world contexts of use and application, they may reveal unforeseen impacts, societal concerns or risks – for instance, to health or vulnerable social groups – that need to be dealt with by society and its institutions. In some cases, the risks related to novelty are overwhelming and lead to dead ends for particular solutions. In others, these can be addressed through technical or institutional adjustments. In either case, there is an inherent dilemma of control (Collingridge 1980) with the introduction of new solutions and particularly technological solutions, given that in early stages of development, when greater control is possible over technology, little

Figure 12.7: Transformation principle 4: Handle uncertainty – don't avoid it

is known about the potential risks that would warrant control.

- Societal adjustments to change. As new practices or systems are introduced, they need to be integrated into existing structures – technical infrastructures, rules and institutional arrangements, as well as bundles of practices – and may require substantial adjustments or even transformations of these structures. This is a transformative process in itself, which comes with its own uncertainties.

These sources of uncertainty and unpredictability call for more anticipatory, adaptive and precautionary forms of governance, including ways to keep future options open. Foresight, scenario planning, horizon scanning, and participatory processes are crucial ways to generate knowledge and the capacity to plan and anticipate future transformations. Speculative futures studies in the arts, social sciences and humanities provoke imagination and the exploration of plural future possibilities – including radical ones – in order to shape the present. This can include centring of Indigenous ways of knowing and being, as well as other relational ontologies (Nelson et al. 2024). Futures studies can support regional development (Oomen, Hoffman and Hajer 2022), countering the hegemonies that create environmental challenges. Anticipatory forms of governance are primarily concerned with developing the capacity and preparedness for future situations (Guston 2014; Vervoort and Gupta 2018) rather than improving the accuracy of predictions. Adaptive and tentative forms of governance are specifically oriented towards accounting for unforeseeable risks and the unintended effects of policy interventions (Stilgoe, Owen and Macnaghten 2013; Kuhlmann, Stegmaier and Konrad 2019). The approach notably emphasizes the need for learning, re-learning, and real-time evaluation, as well as responsiveness to surprises and to limits for control – what could be regarded as greater humility in our collective ability to predict and plan for the future. Lastly, the governance of system transformations must be guided by a commitment to flexibility (Stirling 2010) so that current choices and decisions maintain openness to unpredictable future changes, given that transformative solutions are rarely certain to achieve intended effects, as well as opening space for participation and inclusivity, given that transformative solutions are rarely consensual (**Figure 12.7**).



12.4.5 Inclusivity, participation, plurality and coordination

Principle 5: The governance of system transformations needs to involve actors from different societal spheres and a plurality of worldviews, which implies deliberate forms of coordination, inclusion and participation (**Figure 12.8**).

Transformations are multi-actor and multi-action processes, implying that no actor or action can single-handedly trigger a transformation. Nonetheless, actors contribute to transformations through their relative power, authority and competences, as well as by joining forces with other actors, for example in coalitions, social movements and partnerships.

The governance of transformative change involves different constellations of actors across diverse societal spheres or sectors. In each societal sector, individual actors and organizations are endowed with various resources, competences, power, and logics of action (Avelino and Wittmayer 2016). It is possible to envision different styles of transformation governance concerning

Figure 12.8: Transformation principle 5: Mobilise diverse actors

the particular configuration of lead actors of change:

- Market-led transformations involve a dominance of firms and business actors, possibly with state involvement, as with the model of public-private partnerships as a privileged form of addressing challenges in public management

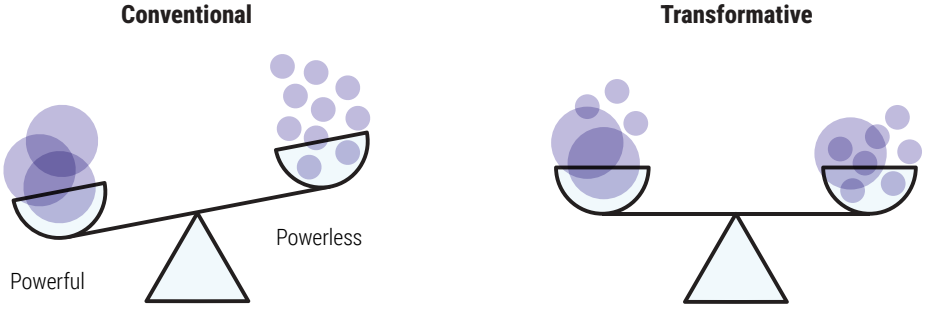
- State-led transformations involve a dominance of State actors – public agencies, governments and municipalities – possibly with a greater emphasis on top-down planning and regulation

- Community-led transformations involve a dominance of local action not driven by profit motives, possibly with the support of civil society – NGOs and associations.

Between these archetypes, real-world transformations will likely involve combinations or hybridization of this logic.

As transformation unfolds, the respective role and power of different actor categories may shift – as has been witnessed with the increasing formalization and commodification of organic food, in a shift away from community-led self-sufficiency towards market-led change with State-level regulation and a continued involvement of NGOs to develop standards and certification. This commodification of organic food has led normative advocates to depart from conventional standards to establish new, more stringent standards for organic food.

Empowerment approaches to transformation suggest that plurality is key because transformation approaches involve contestation over values and ways of being, as they are inherently political processes (Scoones and Stirling 2020). Emancipatory approaches thus actively create space for marginalized ontologies, values and practices (IK & LK Chapeau A). This would include centring Indigenous and other relational ways of knowing and being, and attention to identified causes of unsustainability, such as extractivism and green colonialism (IK & LK Dialogues 2025).



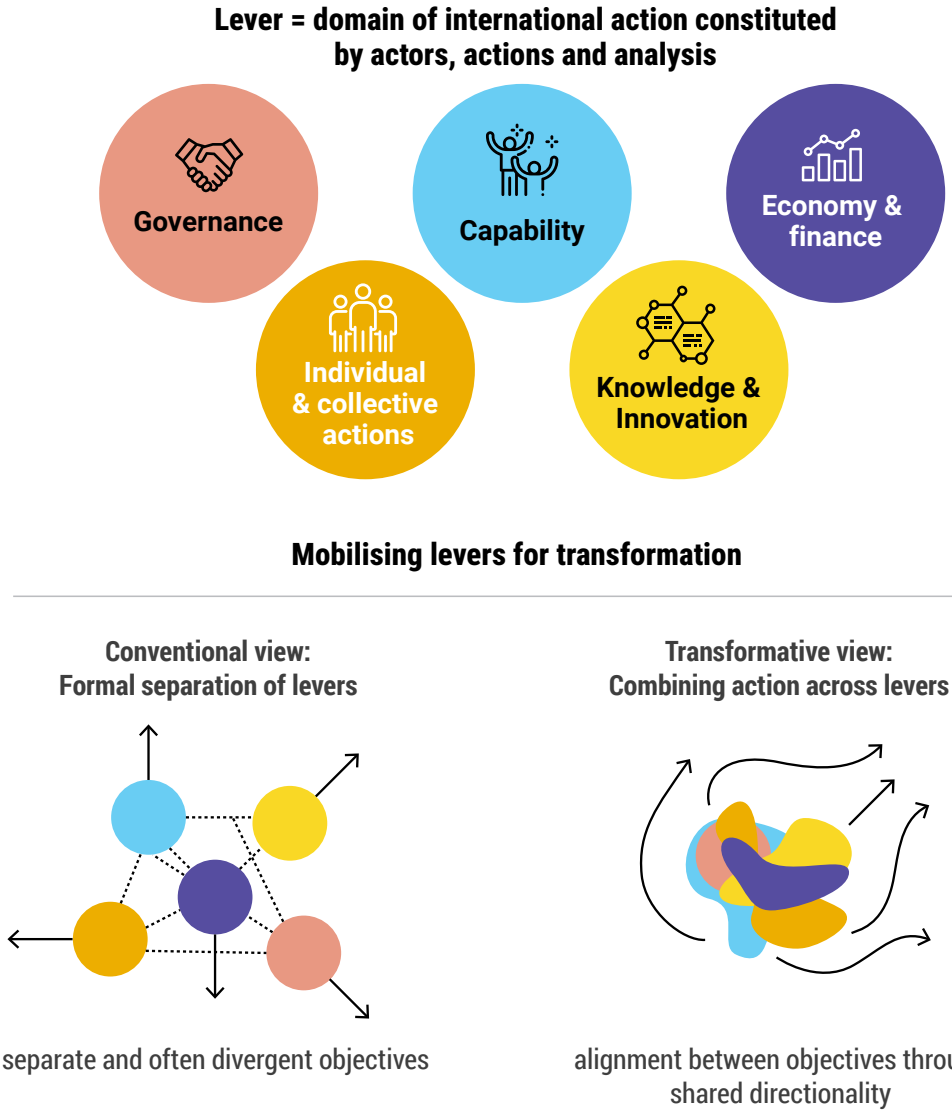
12.4.6 Power and politics

Principle 6: The governance of system transformations needs to address power relations, vested interests and social inequalities through decisive political choices guided by explicit notions of justice (**Figure 12.9**).

Transformations are deeply political because they:

- create winners and losers, in contexts of existing inequalities, unsustainable economies and politics, and uneven accountabilities and effects. Potential losers of transformations include the actors – individuals, social groups, companies and nation states – that are most dependent on existing unsustainable activities such as fossil-fuel extraction, high levels of extraction and consumption of resources, or the use and release of harmful substances into the environment. Transformations can also generate new types of vulnerability, such as environmental and social damages related to the increased demand for lithium extraction to support the projected rise in battery production and use following electrification transformations (Marín 2023). Measures targeted at the underlying causes of unsustainability should target those accountable for damage, such as asset holders, and avoid disproportionate costs for the vulnerable and poor. Loss, vulnerability and related conflicts need to be addressed through adequate anticipation, increased preparedness and compensation measures where appropriate.

Figure 12.9: Transformation principle 6: Don't ignore the political nature of transformations



- trigger resistance to change (Brown 2015). Incumbent actors with vested interests in current systems are likely to resist changes, especially when these question the prevailing distribution of assets, business models or investment patterns – potentially generating stranded assets. Such actors, which typically benefit from asymmetric access to and influence over policy, tend to actively mobilize their bargaining and lobbying power, often in ways that do not safeguard the environment or long-term interests of communities. While compensation measures can be appropriate short-term measures if designed with conditionalities, these need to be supplemented with adequate support for the development of less harmful human activities, that is, guided by a transformation that moderates market values and moves to guiding ethics of care and solidarity (IPBES 2022).

- require new political alliances. System transformations, because of their inherent political nature, rest on the enrolment of actors from across society for the co-production of new societal orientations and hopes for change. Civil society actors and proactive business communities can be important drivers of change (Hajer 2011), while governments can shape enabling environments for markets and support solidarity economy alternatives. Intentional, pluralist empowerment processes that give marginalized actors, broadly aligned with sustainability, a greater voice to challenge hegemonic values and ways of being, are part of coalition building and may intertwine with the efforts of social movements (Scoones et al. 2020). Importantly, non-anthropocentric approaches to transformations include the representation of non-human entities in political decision-making, recognizing the agency, sentience and value of non-human life, as well as the interdependencies across human-non-human webs of life and the recognition of rights under law (Haraway 2016; Puig de la Bellacasa 2017). In the context of unprecedented material prosperity for some but rising insecurity for many and a consequential polarization, combined with uncertainty from dangerous environmental planetary change, accelerated system transformation efforts can also contribute to turbulence (UNDP 2022). This is especially true when transition measures affect those who are already vulnerable and insecure.

- generate challenges for representation and accountability. Because system transformations are fundamental societal changes, they also imply changes in future-making, allowing plural ontologies and values, such as Indigenous Peoples' and other relational ways of knowing and being (IK & LK Chapeau A), to have representation in envisioning and enacting sustainability futures. Devising new eco-social contracts, for example about what new and created worlds could look like, what matters in the future, what needs to be safeguarded, what needs to be abandoned, and the very composition, goals and ethics of society should be achieved through pluralist processes. This implies challenging the status quo, giving voice to underrepresented actors and worldviews, for example, citizens, especially marginalized groups, in democratic decision-making (Scoones et al. 2020), and moderating the voice of overrepresented actors, such as powerful incumbent alliances resisting change, to overcome dominant orthodoxies, such as colonial modernities (Arora and Stirling 2023) and relations of domination (IPBES 2024).

- call for new ways to recognize inherent values conflicts and ontological differences and potentialities. Since system transformations are inherently political processes, they cannot be governed in technocratic ways. However, they represent important opportunities for collective, pluralist and democratic decision-making about societal expectations – goals, values, paradigms and ways of being – and supporting eco-social contracts. Achieving transformations in sustainability requires tackling disconnections from and domination of nature, power and wealth inequalities, and short-termism in decision-making. This requires involve a shift in power relations and practices from relations of domination towards relations of care and reciprocity (IPBES 2024; Nelson et al. 2024).

Figure 12.10: Levers and intersections

12.5 From principles to requirements for intentional action within and beyond existing governance structures

Given the discussion in Section 12.4, the question for policymakers and all stakeholders becomes one of how to address system transformation intentionally in policy and practice. The approach in this GEO-7 report consists of the use of levers to apply the six principles for system transformations. As noted in the Introduction, levers can be defined as domains of societal influence which share a configuration of a broad type of actors, actions and analysis (**Figure 12.10**). The solution-oriented focus on societal systems proposed in this GEO-7 fits well with the choice of levers as it avoids a one-sided categorization in terms of social stakeholders, instruments and tools, or mental frameworks.

Instead, it sees these domains as defined by the interaction of actors, institutions, cognition and action. The concept of levers as intentional forms of transformation was introduced in the Global Sustainable Development Report (United Nations 2019) in 2019 to describe four different "powerful agents of change" – governance, economy and finance, individual and collective action, and science and technology. This offered a concise, high-level list of universal, broad types of deliberate, intentional agency. These are quite different to the emergent, unintended drivers of ecological problems; they are rather conceived as arenas where sustainability solutions may be purposefully sought. It is descriptive rather than normative and encompasses various modes of action and analysis, as well as diverse groups of actors.

The fundamental paradox associated with the concept of levers is that the same domains offering the

opportunity for purposive change are also those that serve to perpetuate the current state of affairs. They lend themselves more readily to incremental rather than transformative change. Theories of transformation share the view that they involve challenging the boundaries between well-established levers. A new mix of governance, finance, social action and technology is needed. Similar to a radical innovation in a business organization that crosses departmental boundaries between research and development and marketing, between human resources and strategy, this would be a societal level analogy. In other words, transformation is only possible through "novel combinations of different levers and the novel collaboration of the respective actors in governance, economy and finance, individual and collective action, and science and technology" (United Nations 2019, p. 27). The levers are defined as domains of intentional action and are then applied to the principles of transformation. While authors acknowledge several sets and intersections of levers, five have been selected, based on the comparison, and discussed at the open-ended meeting on October 2022, and at the first author meeting, held in Bangkok in March 2023, with the following structure of transformation-enabling levers that were agreed and applied in the GEO-7 assessment towards the identification and development of solution pathways and trajectories:

- Economics and Finance
- Individual and Collective Action
- Knowledge and Innovation
- Governance
- Capability

While the definitions of each lever are discussed further in Section 12.6, with details and examples of how to apply the principles to the levers, it is important to note that in light of the transformation needed, the term capability is used instead of capacity-building. The idea of capability moves beyond its narrow sense as training towards the capabilities needed to combine different levers effectively, and to address systemic interventions for transformative innovation designed to enable an effective mix of economic, social, knowledge and governance levers. This GEO-7 report also enlarges the lever of science and technology to a broader one of knowledge and innovation, and recognizes the wider plurality of types of knowledge, including Indigenous Knowledge and Local Knowledge (IK & LK). This is to reflect recent research on innovation, which highlights the importance of innovations in business models, organizational forms, lifestyles and consumption, as well as technology. It also recognizes a much wider plurality of types of knowledge in addition to Western science.

12.5.1 Economics and Finance

This lever includes a variety of instruments and tools for enabling transformative change. These range from the need to offset public debt and debt-servicing costs in the poorest countries, to cutting tax avoidance, and investing in piloting and prototyping innovations (United Nations 2023), as well as ensuring certification and transparency in supply chains. It also involves a range of different actors, including international financial institutions and multilateral development banks, governments, private finance – including venture capital and private equity, philanthropists, pension funds, banks and other investors (United Nations 2023).

It is important to note that economic and financial levers are not deployed in isolation. Policy interventions are often needed to activate nonlinear changes to enable transformative shifts within and beyond the financial sector, capitalizing on these transformative dynamics (Lenton et al. 2023). Governments need to adjust the rules of the game, sending clear market signals through new regulations and providing credible long-term policies and targets in order for this lever to reach its full potential (United Nations 2023). It will take political leadership to reallocate resources to better serve people and the planet, ensuring that no one is left behind. This means re-evaluating what counts as national success beyond traditional GDP and measuring the right things, thereby opening up more diverse appreciations of value (IPBES 2023). More generally, public financial institutions need to recognize that nature must be an integral part of fiscal policy, budgets and investments, especially regarding climate risks and adaptation plans (United Nations 2023).

Many Indigenous Peoples' and other relational ways of knowing and being embrace alternative ways of organizing economies, with economic exchange based upon solidarity and care. Commonly based on concepts of humans as part of nature within an assemblage of all life but with humans decentred, the approach embraces interdependencies that carry obligations of reciprocity and care and allows collective good lives, captured in concepts such as Sumak Kawsay (IK & LK Dialogues

2025). Thus, an option for an effective lever in economic and financial terms is making space for ways of knowing, being and valuing that shape practices enabling a transformation in the predominant ways of organizing economies. This would entail shifting from practices such as private ownership of resources and extractivism towards cooperative and commons-based and solidarity economies (Gibson-Graham 1996).

12.5.2 Individual and Collective Action

Reorganizing social practices and cultural processes by mobilizing individual and collective action is fundamental for large-scale societal change towards sustainability (United Nations 2019; United Nations 2023; IPCC 2023b). People's lives all over the globe, and their supporting social and cultural systems, are affected and challenged by global environmental changes, leading to various coping and response strategies (UNEP 2019; UNEP 2021a; United Nations Educational, Scientific and Cultural Organization and International Social Science Council 2013). Large-scale societal change towards sustainability and globally agreed environmental goals requires new forms of sociocultural orientations – social norms, cultural values and ethical practice – social organization, and the mobilization of groups at various levels across society (United Nations 2023). While major paradigm shifts within contemporary societies take time (United Nations 2023), facilitating the envisioning, exploration, experimentation, adoption and mainstreaming of norms, value systems, behaviour, social practices and ways of living by a critical mass of people is essential.

Behavioural change and the emergence of new social practices are part of a broader process of socialization and culturalization. This can be supported by education, information strategies, social movements, activism, campaigns, financial incentives, regulatory processes and legislation (United Nations 2023). Governments at all levels can influence, incentivize and constrain actions and behaviours. This might include providing an enabling environment for micro-level actions, such as community energy projects, or meso-level actions, including social and environmental movements, as well as new forms of political protests or political lobbying, which can spur new behavioural patterns and social practices (United Nations, 2023, p. 75). Promotion of abundant sufficiency in consumption and championing biodiversity in site-based conservation is important for connected conservation that tackles site-based and distant drivers of land-use change (Carmenta et al. 2023, p.6). Governments can seek to support democratic rights to protest and give support to civil society and trade unions to enable advocacy, campaigns and community engagement work to advance sustainability transformations.

Change can also come through the work of artists, including work that engages communities and explores multiple sustainability futures in contexts of high uncertainty, such as futures that challenge or transcend dominant non-sustainability formations. Arts can shift values and create new visions of the future and ways of being by engaging people not only through analytical thought, but also by engaging people's emotions and different senses, for example, through work on soundscapes, to enhance radical attentiveness and connectedness to nature (Bergmann 2016). Individual and collective action can also exert influence on policymaking, through voting, advocacy and collective protest. Importantly, collective action by communities can prefigure alternative ways of organizing society, based on positive sustainability values (Harmáčková 2023). Social learning and co-production can engage diverse groups across various scales in collective learning about values (Slater and Robinson, 2020). Pluralist approaches are important to inherently political transformation processes (Scoones et al. 2020). They are part of empowerment approaches that create space for marginalized groups, perspectives and forms of knowledge to challenge the status quo (Scoones et al. 2020). Indigenous Peoples and other relational philosophies and associated values of ethics of care represent one such perspective that should be centred as part of sustainability transformations; a reparative approach means dominant worldviews and practices cede or give space to these alternatives (Stein et al. 2024).

Social norms, preferences and daily practices are increasingly influenced by new scientific and technological developments in most spheres of daily life, including social media and other forms of information technology, disrupting existing ways of living. When managed sustainably, this might create new potentials and opportunities to reach sustainability gains on a larger scale, that is, smart living (Coalition for Digital Environmental Sustainability 2022; German Advisory Council on Global Change 2019; International Institute for Applied Systems Analysis 2018; International Institute for Applied Systems Analysis 2019).

Overall, the realization of social and behavioural change – and beyond to societal change including values, philosophies and practices – involves contestation

and collaboration processes, preferable based within a culture of public trust and forms of social engagement, inclusiveness and solidarity, including some minimum safeguards of social security and political or institutional stability.

12.5.3 Knowledge and Innovation

Academic analysis and policy practice increasingly see science and technology as part of a broader and more diverse domain – that of knowledge and innovation. This widening scope views innovation as often the result of an interactive diffusion process rather than the direct outcome of a linear push by science and technology. Innovation arises from a system that includes relational capabilities and experiential knowledge, as well as science and technical expertise. Normally used for the pursuit of market economic goals, this systemic approach to knowledge and innovation now needs to address the 21st century global environmental crises, and awareness of plural ways of knowing and being. Rather than simply promoting more knowledge and innovation, this system requires a new directionality towards sustainability, with innovation systems, actors and goals addressing the plurality of values and ways of being. Many of the critical pressures on the environment arise from growth in knowledge and innovation in dominant political economy paradigms and value systems, which have contributed to economic and social development but have ignored these negative consequences, including the suppression of alternatives. Indigenous Peoples' knowledge includes Indigenous scientific long-term observations, and through Two-Eyed Seeing, this knowledge can be brought together with scientific knowledge in support of innovation. Pluralist transdisciplinary processes can also support innovation through co-creation in response to complex sustainability challenges.

Global economic institutions have begun to recognize that innovation systems have to change. The United Nations Conference of Trade and Development report (UNCTAD 2019) calls for new approaches on innovation in support of SDGs' implementation that are mission-oriented to direct innovation to specific environmental goals. This new directionality needs to be combined with a new diversity to embrace a broader range of social actors and types of social and technological innovation. An Organisation for Economic Co-operation and Development report (OECD 2023) seeks to enable transitions in disruptive times through transformative innovation for sustainability transitions. It also recognizes that better directionality must be accompanied with an array of measures to promote new modes of partnership among diverse actors and a plurality of forms of knowledge. Actions targeting both consumption and production are needed for transformative change (IPBES 2024). The World Bank with the United Nations Department of Economic and Social Affairs, UNCTAD and the United Nations Educational, Scientific and Cultural Organization propose Science, Technology and Innovation for SDG Roadmaps to bring together a diversity of stakeholders from different professional communities and societal organizations through a shared framework and common language (European Commission Joint Research Centre and United Nations Inter Agency Task Team on Science, Technology and Innovation for the SDGs 2021). Plurality goes beyond this and is based on the design of processes that give equal value and space to plural forms of knowledge, such as science and Indigenous Peoples' knowledge.

Knowledge and innovation play a fundamental role in transforming societal systems to address environmental sustainability. Science and technology need to be viewed as part of this broader system, but must be driven by clearer commitments to directionality, for example, mission-oriented innovation policy, and diversity, for example, inclusive innovation. Environmental goals must be integrated with a broader, systemic model of the innovation process. Influential actors are beginning to shift their perspectives and actions to address this issue.

A pluralist approach to knowledge and innovation recognizes that these are political processes, and that dominant thinking and approaches contribute to the global environmental crises due to accumulation imperatives enabled by dominant philosophies and values. Knowledge and innovation based on values of individualism and consumerism could shift to approaches that embrace plural values and forms of knowledge, grounded in values of care and solidarity (IPBES 2024).

12.5.4 Governance

The term "governance" has lacked harmonized definitions. Fukuyama (2015) suggests three main views of governance: first, as international cooperation, second as public administration, and third as regulation of social behaviour. Governance Today (2014) posits governance from the idea of the process of decision-making, noting that governance is also concerned with the structure and processes for decision-making, accountability, control and behaviour. Additional authors, such as Rhodes (1997),

Credit: imagesourcecurated/Envato

Kooiman (2003) and Jessop (2002), further discuss the concept of gatekeeping and the idea of limiting what different actors can and cannot do within a sphere of influence. The United Nations (2023), further draws the attention of governance to the ability of actors and governments to build common narratives.

Four things emanate then for the governance lever for transformation:

- it is a tool to analyse social dynamics and institutions at different levels and thus about decision-making processes – including transparency, accountability, effectiveness, equity – involving collective stakes or both conflicting and cooperative interests, thus ensuring that while it may have a political connotation, it is not only about politics resting with an actor

- the governance lever is about coordination and facilitation, the ability to structure interaction/rules of the games of institutions and whether this as one analyses constrains or facilitates actions and in addition that actors can move this lever of actions within the ambit of constraining or facilitating

- there will be myriad actors involved within each domain with different levels of power and different tools – policy, human and financial – that allow them to participate or not participate or make choices on what type of participation they choose to influence the decision-making within a domain

- the governance lever exists in all other levers as one examines the main governance elements present in sustaining or inhibiting transformation and as one identifies what needs to be transformed within the area of influence of that lever and its domain of influence

Environmental governance is frequently assumed to refer to human decision-making and agency, but growing efforts seek to recognize non-human, that is, plant and animal, agency and sentience in political and legal realms.

12.5.5 Capability

This lever seeks to move the ambit of capacity-building in two areas. Firstly, beyond the mere idea of training and development or the acquisition of new skills often found in linear models' education and training, with the notion of developing competences and capacities for future-oriented issues, for example, anticipation and foresight to systematically anticipate, relearn and improve decision-making across multiple sectors (Rohrbeck, Battistella and Huizingh 2015). The different capabilities include:

- innovate and redesign regulatory instruments and manage market failures

- convening divergent views and encouraging political players and all market actors to work through the required policy instruments to transform or dismantle power and political structures

- negotiation and coordination with actors within their different spheres of influence – material, financial or other – that maintain and sustain the status quo.

A recent United Nations report moved the ambit of capacity-building in its definition to include "activities aimed at strengthening and maintaining the capabilities of states and societies to design and implement strategies that minimize the negative impacts of current social, economic and environmental crises and emerging challenges" (United Nations 2023).

Secondly, capabilities in this GEO-7 report are also applied in light of Amartya Sen's work (2002) describing capabilities as substantive freedoms or functional capabilities. In this theoretical framework, capabilities is viewed in a normative framework in which social arrangements are viewed from the perspective of the extent to which they promote functions they value, i.e. what people can do and be and thus for transformation, allowing a pathway for long-term impacts of change and long-term resilience questions applied to the transformation process. This approach also encompasses Māori philosophy, African Ubuntu, Buen Vivir and many more non-Western perspectives (Bockstael and Watene 2016), facilitating policy perspectives that take into consideration the rights of Indigenous communities (Schlosberg and Carruthers 2010; Watene 2016).

For transformation, six areas of influence emerge in this lever:

- the ability to imagine and explore a multiplicity of sustainability futures that embrace plural ways of knowing and being, such as those of Indigenous Peoples, and embrace living well together to reshape the present

- the ability to anticipate and analyse sectoral and social trends, including current and future desirability

- the ability and willingness to analyse, examine and learn from experience and plural forms of knowledge, especially from Indigenous Communities and Local Knowledge, on what sustains or inhibits sustainability transformation

- the ability to innovate and reverse courses of action, be it at philosophies and values, institutional or practice levels, that have sustained and inhibited transformation

- the ability to "coordinate and resolve conflicts and trade-offs as they arise and in identifying and overcoming other common impediments and system lock-ins" (United Nations 2023)

- the ability to analyse and learn or relearn requires an interdisciplinary and transdisciplinary approach that mobilizes levels of knowledge in different sectors and domains, and other levels of practical knowledge (UBA 2020) and unlearning and new learning via plural forms of knowledge, especially those of marginalized groups (Scoones et al. 2020)

- and finally, the extent to which social arrangements provide value to those applying them, including the rights and freedoms of Indigenous Peoples under the Declaration on the Rights of Indigenous Peoples, of women through gender equality, and of marginal social groups.

12.6 Lessons from experiences of intentional transformative action principles acting on levers

Drawing on the definitions of levers already discussed, this section illustrates the implications of transformation principles when applied to the various domains of intentional actions or levers in concrete settings. For each of the six principles presented in Section 12.4, it provides examples of the style of action possible within different systems, alongside evidence from practical experience.

12.6.1 Illustration of Principle 1

Section 12.4.1 presented principle 1 as follows: The governance of system transformations needs to be explicitly targeted at whole systems and address underlying sources of lock-in related to current system configurations.

Example 1a: Carbon financing

A good example of the need for a systemic understanding of transformative change within the economic and financial lever is the sudden growth of carbon financing in the voluntary carbon market, aimed at investing in carbon offset projects (Selomane et al. 2025). Indigenous Peoples identify carbon and biodiversity offsets as examples of false solutions that adversely affect them (IK & LK Dialogues 2025). Carbon offsetting has the potential to create perverse incentives, for example, in the context of tree planting in open grassy ecosystems in Africa (Bond et al. 2019). Evidence suggests that the potential of such carbon offsets are often overestimated, and the assumed ecological co-benefits of increasing carbon stocks are often incorrect and could result in biodiversity losses and degradation, rather than restoration (Bond et al. 2019; Seddon et al. 2020). The emphasis on carbon offsetting has led to proposals that aim to enhance above-ground carbon across numerous biomes in many forms, from natural forest regeneration, reforestation, tree planting, afforestation, fire abatement and a switch to early burning in tropical grassy ecosystems (Zomer et al. 2008; Veldman et al. 2019; Russell-Smith et al. 2021).

However, these options consider only one metric, carbon-as-stored-in-trees, to the detriment of other metrics, such as biodiversity, livelihoods, health and culture, and biophysical processes, such as fire regimes. This framing further perpetuates a simple model of allowing people to continue their lifestyles in one place as long as they can pay people somewhere else to remove the problem, while not recognizing the full costs to the communities of committing extensive land resources to maximizing above-ground carbon at the expense of other forms of use that also provide ecological benefits (Dooley, Nicholls and Meinshausen 2022). A more systemic understanding of carbon markets and their potentially detrimental influence on local people and ecosystems would allow for a more nuanced implementation of finance to achieve local co-benefits from investment. A socioeconomic perspective highlights that market-based measures in conservation, including climate responses, are inherently reformist, rather than transformative, because they do not address accumulation imperatives or rigid dichotomies between humans and an external "nature" (Büscher and Fletcher 2020). For example, in the Amazon, Indigenous Peoples and local communities are being forced to participate in carbon markets in order to protect their forests and way of life, which often comes with rules and regulations for investment returns that are not aligned with their philosophies, values or practices.

Example 1b: Mobility systems

The transformation of mobility systems illustrates the importance of Principle 1. Fossil-fuelled automobility, and motorized transportation more generally, is a significant source of greenhouse gas (GHG) emissions and air pollution worldwide (Jaramillo 2022). It is particularly intense in and around large urban centres. While these problems have been known for decades, difficulties in addressing the environmental effects of automobility point to the systemic nature of the problem and the importance of deep lock-ins related to mobility patterns and paradigms (Sheller and Urry 2000; Sheller and Urry 2016). Prevailing strategies for the "greening of automobility" are insufficient to enable the structural shifts in mobility (Banister 2008) that could lead to far-ranging and lasting environmental improvements.

Such strategies, while relevant, are limited in their overall potential because they focus on end-of-pipe solutions, for example, catalytic converters reducing particular pollutants, or substitutions, for example, biofuels or electric mobility, that tend to displace problems or generate new issues, such as competition for land and induced deforestation for biofuels, pressure on critical minerals and induced emissions from power generation for electrification, without addressing underlying barriers to more sustainable forms of mobility and rampant growth in mobility needs (Wells 2023). The electrification of cars is an iconic illustration of non-transformative policy: it sets all expectations on a technological substitute, while contributing to reinforce the systemic lock-ins related to automobility patterns and increased car dependence.

A systemic perspective on mobility instead points to the need to combine interventions on multiple fronts, including the greening of mobility, reducing the need to travel, enabling modal shifts to alternative modes of travel – such as walking, cycling, public transport and ride-sharing – and land-use changes (Banister 2008). Other interventions could explicitly target the phase-out of automobile dependence, including car use and parking restrictions. Such combined approaches are increasingly the object of urban mobility experimentation programmes (Haarstad et al. 2022). However, it is essential that such programmes are not focused solely on individual innovations, but also take a more systemic approach to provide tangible, working alternatives to individual motorized transport.

12.6.2 Illustration of Principle 2

Section 12.4.2 presented principle 2 as follows: The governance of system transformations needs to jointly address opportunities and challenges in new and existing systems, through explicit choices resolving contradictions between what must be developed, phased out, preserved and avoided, as well as ensuing contradictions

Example 2a: Phasing out nuclear power within the framework of the Energiewende in Germany presents some lessons to be learned:

Large-scale system transformation, like the energy system, requires the organization and mobilization of a political and broader societal consensus on desirable, feasible, and affordable energy future options (Reusswig et al. 2016; Arifi and Winkel 2021; Krüger 2022). Experiences from the Energiewende energy transition plan in Germany shows that social movements and local initiatives play an important role in articulating various future options, creating the societal seedbed to mobilize active support towards the restructuring of the entire energy system from a dominant centralized system of nuclear power towards a more decentralized system of energy production, including various forms of community-based renewable energy-production systems (Sciullo et al. 2020).

Here, individual and collective actions create enabling environments, complemented by legislative, economic and technological developments, to facilitate multiple forms of public ownership of the energy system transformation within the spectrum between globalized energy markets and local energy sovereignty (Rommel et al. 2018). Social movements and local initiatives play a vital role in mediating between competing options, and by mobilizing and accumulating the needed social, economic and political capital to phase out existing forms of energy-production systems, while investing in the creation of a more sustainable, secure option in the long run (Sciullo et al. 2020; Krüger 2022).

Example 2b: Agroecology – developing alternatives to conventional agriculture and maintaining traditional local agricultural practices

Contemporary agrifood systems and related practices are responsible for many persistent environmental problems, such as water pollution, soil degradation, pressures on land use and GHG emissions, and significant pressures on life, including biodiversity loss, health effects of transformed food and persistent chemicals, and water scarcity (Camanzi and Troiani 2021). These impedances are directly attributable to the global diffusion of conventional agricultural practices since the second half of the 20th century. This has been driven

by the primary objective of increasing productivity and year-round availability of a large variety of foods, enabled by the deployment of input-dependent and resource-intensive modes of production, such as synthetic fertilizers and pesticides, seeds, and mechanization, and the intensification of productive units, that is, the concentration and amalgamation of farmland. In some parts of the world, such techniques have spread to the majority of farmland and food production, while in other contexts, traditional farming techniques or extensive farming still prevail (Rathod 2023; Hamadani et al. 2021). Accordingly, strategies for reducing the ecological impact of agrifood systems require practices that are more considerate of human-nature relations, but their orientation and priorities depend on the dominant system configuration. Agroecology promises the transformation of agrifood systems according to more sustainable practices, which is at the heart of the Food and Agriculture Organization's Common Vision for Sustainable Food and Agriculture (Food and Agriculture Organization [FAO] 2014), a concept that has garnered widespread support across United Nations institutions and the international community.

Rather than prescribing specific solutions, the agroecology movement and institutionalized discourse are constructed around 10 core elements that can act as guides for holistic food-system development and transformation. The means for implementing agroecology in practice are diverse and strategies should rest on a combination of interventions. Further, the implementation of agroecology largely depends on local food configurations and related transformation contexts. In the case of intensive farming, such as the monocrop cereal plains in Europe or North America, adopting agroecology requires radical change of conventional farming systems towards environmentally less harmful practices. This largely hinges on support for the development and deployment of alternative practices, for example, organic farming, multifunctional agriculture, conservation agriculture, and short food chains. Contexts where conventional farming has not made such significant inroads and where traditional, less intensive and environmentally harmful practices persist on a wide scale include multifunctional agriculture practised around river deltas or mountain agricultural landscapes. In such cases, the main priority for implementing agroecology is about preserving established practices and ensuring their resilience against the pressures of conventionalization (Hamadani et al. 2021; Somashekar et al. 2024).

12.6.3 Illustration of Principle 3

Section 12.4.3 presented principle 3 as follows: The governance of system transformations needs to articulate near- and long-term solutions in sequences of action enabling constructive linkages between multiple temporalities and accounting for non-linear dynamics

Example 3a: Solidarity economy innovations for transforming food and agriculture

One proposal to reshape food systems is to establish science-based standards for minimum sustainability, to be called Codex Planetarius (Loconto 2024). However, solidarity-economy approaches focus on more locally, self-determined regional or subregional food systems and governance innovations, many examples of which were seen during the COVID-19 pandemic, such as urban bartering and exchange (Nadal and Nazar-Beutelspacher 2023). In Italy, innovations range from microscale community and place-based initiatives, mesoscale territorial assemblages and convergences of initiatives and interactions with local and national public institutions and international movements (Rossi et al. 2021). Specific Italian examples include consumer-producer pacts on the provision of specific products, community-support agriculture for the participation of citizens and sharing of economic risks, and participatory guarantee systems. Italian circular solidarity-economy approaches include emergency support funds, community exchange schemes, and resistance to land-use planning decisions that remove land from agroecological production and community-based controls (Rossi et al. 2021). Linking such place-based microscale initiatives can scale them up (Escobar 2021).

One of the main characteristics of this dynamic is the ability to configure opportunities to become socially engaged as part of the movement in various social roles, increasing the level of involvement of people and institutions with various different backgrounds and interests. Additionally, the mobilization potential of a social movement creates opportunities to become a relevant player in the game, influencing the course of political agenda-setting, or to become a kind of standard-setter, or an institution of public trust (Harris 2021).

Example 3b: The role of shocks on near and remote landscapes

Large-scale industrial accidents provide a valuable illustration of the role that shocks can play in established systems. Major shocks can significantly alter the trajectories of sociotechnical systems and their governance, by accelerating change dynamics, reorienting established pathways, or leading to entirely new pathways. However, the potential effects of shocks is mainly dependent on the conditions in which they occur, the extent of preparedness for such shocks, and the political ability to seize related windows of opportunity (Johnstone and Schot 2023). Accordingly, shocks will not have the same effect in different contexts.

The Fukushima nuclear accident in Japan in 2011 is a notable example. This major nuclear disaster had a profound effect on the discourse, status and long-term future of nuclear energy worldwide, but the effect was different in each country. In Germany, for instance, a country in which anti-nuclear movements had succeeded in stimulating a society-wide debate about the possible end of nuclear power, it bolstered and accelerated an existing programme of nuclear phase-out, which recently completed its final phase (Appunn 2021). In France, the Fukushima accident triggered public and parliamentary debate, but this was short-lived and translated into a reinforcement of a regulatory approach to risk management that kept the politics at bay (Arnhold 2020) and ultimately allowed a nuclear renaissance.

12.6.4 Illustration of Principle 4

Section 12.4.4 presented principle 4 as follows: The governance of system transformations needs to be supported by new ways of dealing with uncertainties, anticipation and plural ways of knowing and being

Example 4a: Transforming ways of thinking and doing

Dealing with uncertainties and anticipating new challenges call for a rethinking of ways of knowing and requires a transformation of the entire societal system. The type of innovation needed to achieve such aspirations is likely to involve a transformation in customary ways of thinking and doing. Such challenge-led directionality requires an innovation policy to promote a much higher degree of diversity than is traditionally the case. Knowledge and innovation need to shift from an individual project focus to facilitating a system-wide portfolio of social and technological innovation activities. Systemic barriers such as constraints by corporate organizations that control much of the ecosystem may often have a higher incentive to stifle multiple pathways of thinking and doing. Thus, it is important to access the various lock-ins of various stakeholders that in turn lock in multiple pathways of solutions. Innovation opportunities should not be confined to the preferences of currently dominant technical advocates or incumbent businesses.

An over-selective focus on emerging new technologies that offer transformative promise can be a trap of making an early speculative bet on a solution-in-search-of-a-problem. An alternative focus on challenges, rather than technologies, avoids this trap. However, if the challenge is very broad in scope, it can face the opposite pitfall: the risk of an over-general problem-in-search-of-a-solution. The participation of a wide variety of actors and the exploration and experimentation with a rich assortment of different innovation pathways are not ends in themselves and may lead to dissipative and directionless diversity. Some sort of balance is needed.

Directionality and diversity present a classic innovation dilemma (Steward 2009) of which many are well known in the business world of innovation management. A portfolio approach can recognize the multiple time frames of different innovation pathways and also the inherent uncertainties in the innovation process itself. The targeting of a challenge is strongly directional, but a variety of innovative solutions need to be nurtured, both in terms of sociotechnical type and maturity or readiness. Near- and long-term perspectives need to be maintained, and strategy should not be dominated by a particular solution advocate. There should be new spaces for user-led social innovation in addition to producer-driven technological innovation.

System innovation portfolio guidance can be pursued in two different ways. It can be used as an ex-ante approach to shape the design and implementation of projects and programmes by funders at the regional or national level. The best example is the Swedish Innovation Agency VINNOVA – a pioneer of challenge-led system innovation policy. Alternatively, portfolios can be constructed as an ex-post approach to map and orient a variety of existing ongoing projects, irrespective of origin or funding source, towards a system-framed mission in a more explicit fashion. These are then treated as a portfolio through coordinative or interactive measures. The European Institute of Innovation & Technology's Climate-Knowledge and Innovation Communities implemented an innovative approach

to constructing project portfolios from existing city-level projects within their Transition Cities initiative.

Optimally, the capabilities required for transformation need a new orientation of how problems and solutions are framed and models of change are represented to understand transformation. For example, reductionist representations of change – as in numeric model representations – are insufficient. They need to be complemented by other forms of anticipatory and future-oriented knowledge. Instead, capabilities that require models and scenarios criticism are required that then build-in imagination and diversity, that challenge prevailing logics such as optimization and efficiency, and manage performativity. These are not easy to do in reality, but recognition that existing logic frameworks often used in scenario modelling may not be adequate will be a start to re-orienting our learning and need to relearn.

Example 4b: Environmental contributions of digital transformations

The uncertainties around the positive and negative environmental effects of digitalization provide a useful illustration of the need for anticipatory approaches to system transformations and regular re-evaluation and adaptation in the face of unforeseen concerns and risks. Digitalization has long been perceived as enabling a significant reduction in the environmental influence of human activities connected to the transportation of people and products, for example, a reduced need to travel and accumulate material goods (Mondejar et al. 2021). However, without denying the significant benefits of digital transformations notably in terms of access to information for all, it has become clear that their ecological effect is at best ambiguous. There is evidence of a growing footprint of digitalization (UNEP 2021b). This concerns significant GHG emissions from energy use, notably in server farms related to cloud computing and storage, material waste accumulation due to planned obsolescence and low levels of e-waste recycling, and significant pressure on mining for rare resources and related environmental and social impacts (Creutzig et al. 2022; Sareen et al. 2023), which tend to be unevenly distributed globally (Sovacool et al. 2020).

The considerable uncertainties clouding the environmental implications of digitalization may make any attempt at accurate prediction futile. This unknowable character of the digital carbon footprint and the associated risks of it spinning out of control suggest that the main priorities should be set on avoiding risks, mitigating adverse effects, and enabling adaptive governance frameworks for rapidly changing circumstances (Gritsenko et al. 2024).

12.6.5 Illustration of Principle 5

Section 12.4.5 presented principle 5 as follows: The governance of system transformations needs to involve actors from different societal spheres and a plurality of worldviews, which implies deliberate forms of coordination, inclusion and participation

Example 5a: Legal instruments to enforce coordination, plurality of voices and gender inclusion and stakeholder participation in Kenya

In Kenya, the inclusion and consultation of all stakeholders were enshrined in the country's Constitution in 2010. This was further enacted in the counties to ensure that rural communities and Indigenous Knowledge among the over 47 tribes in Kenya can share and debate the previous top-down forms of policies. Examples include changes in environmental social impact assessments that now demand that those affected or potentially affected have a voice in shaping policy decisions. Gender considerations are also now taken into account with development programmes now enforcing gender inclusion as a key part of the programme's success across the country. For example, the National Gender and Climate Action Plan in Kenya aims to ensure that investments, policies and programmes are inclusive, equitable and effective.

Programmatic examples include Voices for a Just Climate Action, which aims to ensure that local civil society and underrepresented groups take on central roles as creators, facilitators and advocates of innovative and inclusive climate solutions to address climate change issues. Various approaches have been initiated to address the effects created by climate change, and ultimately, steps to reduce carbon emissions in a bid to forestall environmental degradation and pollution. The Voices for a Just Climate Action is a lobby and advocacy programme implemented by the World Wide Fund for Nature Netherlands, SouthSouthNorth, Akina Mama wa Afrika, Slum Dwellers International and Hivos, and is an example of the many programmes now in place to ensure the inclusion and multiplicity of voices in the environmental space.

A significant change in the plurality of world views in Kenya and Africa has been accelerated by the large

Credit: ©UNEP

number of youth using social media. The rise of different young voices is now seen within the context of social media where Kenyans active on social media raise concerns that now demand policymakers' attention. In effect, this has increased the self-regulation of government by citizens who can now check on the progress of policies. It also allows the inclusion of various diverse voices and their views to be heard and considered. The rise of information technology has further enhanced the accessibility of decision-making in the country, ensuring that alternative news media from grass-roots individuals is now accessible, thus reorienting modes of knowing and doing.

Example 5b: Plurality in biodiversity conservation for Indigenous communities

Traditional protectionist or fortress-conservation approaches traditionally had adverse effects on Indigenous Peoples when redesignation of Indigenous Peoples' lands would lead to dispossessions and displacements (Adams and Mulligan 2003). Plurality in conservation means recognizing multiple forms of knowledge with varying definitions in different academic disciplines, including divergences between the natural and social sciences, but also among different communities and groups who have lay knowledge, including "situated, emotive and intimate" relations with non-human life, and differing conceptions of how to live well together with nature (Pascual et al. 2021). Mobilizing "scientific knowledge and lay knowledge, conservation science policy and practice would be better equipped to identify and facilitate more legitimate and effective goals and actions" rather than imposing contested frameworks (Pascual et al. 2021, p. 569). More collaborative approaches to site-based biodiversity conservation are collaborative in nature (Carmenta et al. 2023), being context-sensitive and prioritizing questions of ethics and justice for humans and non-humans (Nelson et al. 2024). For example, Indigenous Peoples' ways of knowing and being, including their relationships with themselves, lands and others – including plants and animals – are imbued with notions of interdependency and recognition of the vitality and agency of lands and all life, aligned with values and practices of reciprocity and care. In these relational ways of knowing and being, Indigenous Peoples view nature not as something separate from themselves but as deeply connected, and often as kin, as sacred or as a spiritual entity (Bawaka Country et al. 2015).

Valuing nature beyond utilitarian frameworks and instrumental values creates opportunities for more just and effective approaches to conservation, given the effectiveness of Indigenous Peoples' guardianship and care for lands and life. The approach of Indigenous Peoples and Local Communities Conserved Territories and Areas, known as the ICCA Consortium or "territories of life", is a valuable one. It aims to conserve Indigenous territories and protected areas, cultural land and seascapes, sacred natural sites, migration routes of mobile Indigenous Peoples, biocultural heritage territories, and community-managed areas. These involve close connections between

custodians and Indigenous People or local communities, and they lead governance for the area, with governance and management decisions positively contributing to nature conservation of the area (IPBES 2024; Sajeva, Borrini-Feyerabend, Niederberger 2019). The principles guiding such conservation have the potential to support sustainable futures worldwide (Nelson et al. 2024). Efforts are under way, for example in New Zealand, to assign rights to nature – such as rivers and forests – by the Rights of Nature movement (Banwell et al. 2024). Non-human – that is, plant and animal – representation is being assigned to the boards of cooperatives (Nieuwe Instituut 2021) and in transdisciplinary action research projects that embrace plurality, for example, the Embassy of the North Sea. This is a ten-year Dutch initiative involving ecologists, artists, communication specialists and communities, seeking to "listen to", "speak with" and "negotiate for" the North Sea, which has been recognized as a living entity with agency (Embassy of the North Sea, n.d.). It is important to note, however, that site-based conservation is increasingly challenged by forces beyond the territory, which means that action is required to address the global political economy, to shift cultural narratives, to challenge the most impactful sectors and to transform governance systems (IPBES 2024). This also means addressing issues such as perverse subsidies, and measures to manage telecoupled agricultural commodity trade through a connected conservation approach (Carmenta et al. 2023).

12.6.6 Illustration of Principle 6

Section 12.4.6 presented principle 6 as follows: The governance of system transformations needs to address power relations, vested interests and social inequalities through decisive political choices guided by explicit notions of justice.

Example 6a: Financial subsidies

Money is often related to power; the financial system tends to wield some of the most powerful mechanisms for both maintaining the current system and transforming it. The example of subsidies provides a clear illustration of how politics influences the asymmetric deployment of money to certain sectors and actors, often at the detriment of sustainability and equity goals. Creating a more just system that aims to rectify asymmetries in power and access to capital requires powerful actors to reconfigure how they allocate financial resources. Globally, fossil-fuel subsidies totalled US$7 trillion or 7.1 per cent of GDP in 2022, reflecting a US$2 trillion increase since 2020 due to government support from surging energy prices (WEF 2023a; IEA 2025a). Subsidies are expected to decline in the near term as energy price support policies are unwound and international prices fall, but then to rise to US$8.2 trillion by 2030 as the share of fuel consumption in emerging markets – where price gaps are generally larger – continues to climb (WEF 2023a; IEA 2025a). Subsidies are intended to protect consumers by keeping prices low, but they come at a substantial cost: they lead to higher taxes and borrowing or lower spending; promote inefficient allocation of an economy's resources, hindering growth; encourage pollution, contributing to climate change and premature deaths from local air pollution; and are not well targeted at the poor, mainly benefiting higher income households. This not only applies to subsidies of fossil fuels, but also in the fisheries sector where overfishing and inequitable access to resources are prevalent (Sumaila et al. 2019).

Removing subsidies and using the revenue gain for better-targeted social spending, reductions in inefficient taxes, and productive investments can promote sustainable and equitable outcomes. The removal of fossil-fuel subsidies would also alleviate energy security concerns related to volatile fossil-fuel supplies (WEF 2023a; IEA 2025a). The 2022 the World Trade Organization agreement on fisheries subsidies that established binding global regulations compelling governments to assess the legality and sustainability of the fishing activities they subsidize, showcases the potential for transformative change if the power of the financial sector is leveraged for more sustainable and equitable outcomes (Sumaila et al. 2024). In February 2024, World Trade Organization members were uniquely positioned to institute additional regulations that eliminate harmful subsidies, demonstrating their dedication to safeguarding the ocean and charting a more sustainable and equitable pathway forward with a commitment to more equitable trade. This demonstrates how political choices are necessary to harness a financial lever to achieve transformative change for the world's oceans and resources. Changing economies will also require more than specific policy levers; shifts in values and ontologies are central to

3 The BRICS is a group formed by eleven countries: Brazil, Russia, India, China, South Africa, Saudi Arabia, Egypt, United Arab Emirates, Ethiopia, Indonesia, and Iran.

transformations. Transformations require moderating individualism and materialism and amplifying the values of care and solidarity (IPBES 2022; Harmáčková et al. 2023). Alternative visions of economic exchange beyond accumulation already exist in diverse economies around the world (Gibson-Graham 1996) and they are particularly strong within Indigenous philosophies, which present some of the best examples of living sustainably within planetary boundaries (IK & LK Dialogues 2025).

Example 6b: Realignment of country-level governance systems in Africa to mitigate disparities across multiple sectors and thus realign power dynamics and vested interests to include multiple actors

Many countries in Africa face persistent challenges since attaining independence in the 1960s in ensuring the equitable distribution of resources. The power dynamics and vested control, not only from the colonial powers but also from the minority in those countries who have controlled the various domains of economic control across various sectors, have ensured that a select few control natural resources. While the 1990s saw many African countries incorporate human rights and the rule of law, not many have been able to alter the power dynamics and actors that control various sectors. Global realignments such as the BRICS[3] group are viewed as providing alternative options and realigning the lock-ins and vested interests that dominate Africa's governance structures.

At the country level, Kenya's 2010 constitutional change provides a good example of reorienting and navigating power dynamics and vested interests. While it still has a long way to go in ensuring social participation, the new Constitution initiated the division of the country into 47 counties with a political structure that removes power from the central domain of the Presidency. Like the federal system in the United States of America, the Constitution stipulates that decisions across many sectors must be made at the county level. This has shifted the power dynamics, with those marginalized communities now having a voice in the decisions that affect day-to-day resources in their communities. The changes in power from the top at the central level have also started to alter the vested interests entrenched in various sectors. These include: 1) altering the power dynamics and vested interests on infrastructure in the counties; 2) political representation, gender participation and access to political resources; 3) changing and challenging the social structure of society across terms such as rural and city and thus altering policy design, now that each county has a centralized capital; and 4) changing and challenging the age structure, income and access to development projects (Government of Kenya 2010).

The above examples serve to show how levers – domains of intentional action – when applying the principles, can be mobilized to transform entire systems and in doing so, ensure that transformation takes place.

12.7 New policy design for our times

This chapter has provided a conceptual analysis of the dynamics of transformation. In doing so, it has identified six core requirements for transformation and the ways in which these principles can be applied within the levers. These requirements shed light on pathways for dealing with the inherent challenges in transforming entire systems. The requirements are framed within the need to ensure that transformation is not purely normative or theoretical but also meets the practical challenges of our times. They provide a mental map to be used strategically by all actors in society to achieve whole-system change.

In its attempt to ingrain the conceptual analysis within the day-to-day actions of actors, the chapter highlights the role of levers, which it defines as "domains of intentional action" in providing a means for dealing with system transformation. Unique to this GEO-7 report is the role of policy actors in appraising bundles of actions within and across levers. In particular, the policy actor is presented with the six principles and the levers as heuristic models – a conceptual framework – that can be used to define systems and their lock-ins as explicit and shared frameworks for action. This aims to combine the dynamics of phase-out and phase-in with the anticipation of change over the near and long term, to seek modes of intervention that acknowledge uncertainties, and to engage with diverse constellations of actors affected differently by system transformation and with contrasting power and influence.

This conceptual framework provides the actor with the ability to reshape entire sociotechnical, socioecological and socioeconomic systems that need purposeful action to move beyond the many isolated fragments and target whole-system change. The six principles combined with the levers present a set of new practices of policy design that provide purposive action towards collectively defined solution pathways as a basic

condition to enable system transformation through meaningful and targeted politics, governance, and institutional capabilities (Patterson et al. 2017; German Environment Agency [GEA] 2018; United Nations 2023; Bertelsmann Stiftung 2024). Further, it shows that the conventional separation between levers is ill-suited to transformative processes that inevitably cross the boundaries between, for example, the worlds of business strategy, personal lifestyle, government regulation, finance and technology. Instead, the new policy design envisioned in this chapter reveals new boundary-spanning intersections and institutional work between the multiple arenas of societal influence.

12.7.1 Rethinking the politics and political culture of system transformations towards societal sustainability

A key message is that system transformation is a lightly distributed and coevolutionary process that does not fall neatly under the label of public policy (Hajer et al. 2015; GEA 2018). The chapter challenges current institutional set ups and governance practices to rethink their relationship to and influence over prevailing societal structures, market economies, political spheres of influence, patterns of social interactions and arrangements, the institutional structures that arise from these arrangements, collective identity formation, and the forms of political participation available to citizens.

The chapter also acknowledges that the pursuit of urgent sustainability goals requires formal governance institutions to establish goals and frameworks, particularly at national level, to enable the shared framing of problems and solution spaces, to leverage the allocation of public finance, or to support deliberative processes for the formulation of political solutions (United Nations 2023). This interplay of different layers of governance suggests that system transformation as a political means of developing and supporting solution pathways calls for a new political rationality, that is, a new perspective on handling and influencing societal and political realities within a world of growing complexity, volatility and political ambiguity (Eden et al. 2021; Antonacopoulou 2018).

Such a new perspective on the politics of transformation can underpin a new era of purposeful policy and action – policy-by-design, not policy-by-disaster (Nassehi 2024). It needs to encompass the cultural, political and material aspects of human life and how these aspects are socially organized, normatively codified, and structurally institutionalized towards an envisioned societal reality. The formulated principles for transformation can help facilitate the responsiveness, agency, and actions necessary. Thinking of system transformation as a new political practice may lead to fundamentally reconfiguring existing priorities of established arrangements and social order, challenging institutionalized routines, political paradigms, patterns of responsibility, cultural identities, and role models (GEA 2018), as has been shown through the principles when applied within the levers.

The ensuing new role for government not only presents a historical opportunity and responsibility to address major shortcomings of the present handling of environmental crises, but also a requirement to develop analytical and strategic capabilities within existing governance structures and organizations. Within this new understanding of the politics of system transformation, four areas of governmental responsibility are identified as key to system transformation: orienting, aligning, navigating, and legitimizing.

12.7.2 Orienting: humble and open approaches to directionality

Clearer directionality towards sustainability goals, as shown for example by the pursuit of climate emission targets, needs to diffuse more generally in the policy system. However, given the recognition in this chapter that system transformations are inherently complex and uncertain, the scope for planning and control is limited (Stirling 2010). A purely top-down and technocratic approach is neither effective in practice nor ethically justified from an equity and justice perspective (Stirling 2023). Governing system transformations takes uncertainties seriously, and rather than claiming predictability, it gives status to unknown future developments (Beck et al. 2021). Anticipation, precaution, flexibility and reversibility are the guideposts for such an approach. Because the governance of system transformation is not a "deterministic endeavour" nor a "Fordist project" (Nassehi 2024) that promotes conformism to a "one best system", it is essential to have a plurality of possible orientations and pathways that may enable more sustainable systems and societies. Variety and diversity are requirements for system transformation.

Credit: vunavgallery/Envato

Nevertheless, in addition to these precautionary principles of flexibility and diversity, policy also needs a refreshed sense of directionality to address environmental goals, recognizing that transformation is not just a technical matter but always about political and value choices (Scoones and Stirling 2020). Challenge-led missions and transition policies pursue clearly defined sustainability targets while leaving open the types of system transformation to be followed. These new forms of collective directionality and targeted systems (OECD 2024) reconfigure purposive policies and intentional actions towards a more open, non-deterministic system transformation.

Meta-analysis on theories of change shows a significant shift (Juri, Terry and Pereira 2024) from a linear model of "solutionism" – clear causality and input-output as the modus of problem-solving – towards an interactive model of inter-relational agency, network building and interface management (Kok, Loeber and Grin 2021). These new policy practices for system transformation shift attention from the "grand design gesture" (Nassehi 2024) with its often unrealistic claims of radicality and totality. Instead, they draw attention to a more grounded appraisal of the continuously evolving potential of system transformability, less driven by the advocacy of specific technoscientific promises.

12.7.3 Aligning: promoting favourable and discouraging unfavourable alignments

As already discussed, system transformations involve fundamental changes within material, relational and institutional dimensions. Ongoing changes may be contradictory or even pursue environmentally detrimental outcomes. A significant task within the politics of transformation is to generate and sustain positive alignments while avoiding and reducing negative alignments of intentional actions, thereby shaping the configuration of agency. At actor level, this means empowering specific networks and alliances, while discouraging or disbanding alliances working against collectively agreed goals. The process of transformation is a widely distributed one, involving a multiplicity of actions and actors, as well as a vital plurality of positions and worldviews. Research on the dynamics of transformation shows that top-down, technocratic control models are limited and sometimes counterproductive. It also indicates that uncoordinated bottom-up initiatives, although important as envisioned models of transformations, are usually heavily circumscribed, fragmented and difficult to scale or generalize (Easterly 2008; GEA 2015; GEA 2016).

Coordination can be sought through the exploration and experimentation with novel, more effective multilevel models of transformation. This effort requires the identification of interactions, potential tensions and scope for alignment between actions, agency, power positions, and the actors supporting them. The search also requires clarification of the terms and boundaries of desirability in contrast with existing forms of normativity, and regulatory regimes (Forst and Günther 2021). The policy-mix approach

Credit: alexlucru123/Envato

seeks to align a diverse range of public interventions of different types and various domains in a structured and formal manner. Transformative innovation policy can promote a project portfolio approach that involves a variety of actors around common goals (Gunningham and Sinclair 1999; Boas, Biermann and Kanie 2016; Tomor et al. 2019; Richard et al. 2020; Chenoweth and Al-Masri 2021).

12.7.4 Navigating: mapping transformation potentials and evaluating change

The ability to navigate transformations requires individual actors to position themselves in relation to one another, both spatially and socially, as well as temporally. They need a sense of their role in established or emerging systems, as well as an insight into the trajectory and likely timescale of system change. Government policy can play a critical role in facilitating this by enabling society-wide processes of mapping the types and dynamics of system transformation. Many countries have initiated such policy approaches for the net-zero transition, and this transition-policy approach has much more general applicability (United Nations 2023; GEA 2018).

Actors also need new capabilities for interaction and anticipation to navigate system transformation more strategically, either within the context of multi-actor approaches or as part of organizational routines. Many policy initiatives have developed methods and arenas to build such capabilities, including foresight processes, living laboratories or formative evaluation. Place-based approaches seem to be more effective in building such capacity, because of their grounding in contextual intelligence. Foresight is one type of policy process that may be designed to facilitate participative interaction between actors in envisioning futures and facilitating alignments (Murphy and McDonagh 2016; Svenfelt et al. 2019; EEA 2019; European Commission 2021; GEA 2023; Matti, Bontoux and Jensen 2025).

Within a policy design in governing system transformation, developing new policy competence for navigating change becomes increasingly important. Mapping and evaluation of systems and current trajectories of transformation potentials, and monitoring change processes in the making, requires transformation knowledge and formative principles of evaluation. Knowledge and training to strengthen strategic, procedural, and mediating competencies of

civil servants and public agencies can work along with handling normative orientation and conflicting norms to safeguard long-lasting directionality, ideation and editing of political and societal choices (GEA 2021; Jacob et al. 2021).

12.7.5 Legitimizing: political integrity and justice in a polarized world

The policy changes aimed at facilitating system transformations for sustainability present a range of challenges and opportunities for enabling political consensus-building and legitimacy, while mediating between different interests, modes of responsiveness and responsibility, material and non-material trade-offs, private and public resources, and investments for transformation. They imply a more active engagement of citizens and stakeholders in deliberative procedures, political decision-making processes, and strengthened political-administrative management capacities (Hammond 2020).

The political task of governing the inherent "systemness" of complex systems and the transformability of real-world social, economic and political pluralities requires appropriate policy conditions to facilitate the processes of transformation. Such policy conditions include rules of conflict regulation deriving from the transformation, with voices to mobilize collective agency across and beyond existing power asymmetries (Le 2024; Francis 2004). In addition, investments in strategic political communication that enhance the capacity for societal self-orientation and public trust in times of multiple crises and post-polarization need to accompany opportunities for better accessibility to various forms of social involvement and deliberative processes (Friedrich Naumann Foundation 2024; Kleinfeld 2023; Nassehi 2021).

12.8 Towards an operationalization of system transformations

This chapter suggests enriching the public sphere for system transformation. This chimes with a new reorientation by many governments from the market prioritization of the last 30 years, but it also clashes with expressions of populist backlash. There is little doubt that the policy agenda of transformation will be embroiled in these broader political currents in the coming decades and its proponents will need to engage with them.

In addition, the chapter has acknowledged the different policy perspectives among the proponents of sustainability transformations themselves. A spectrum of reform, revolution or reconfiguration has been presented to capture different views of the prospects for current policy systems to innovate sufficiently to enable transformation. This chapter's modest aspiration is that it has identified at least some spaces within the various governance spheres where opportunities for constructive engagement exist to promote sustainability transformations now and in the near future.

A common methodological approach is therefore needed to harness the richness of theoretical and empirical knowledge for system transformations discussed in this chapter. Chapter 13 provides this approach through an operationalization of the principles in a 7-step methodology. This methodology enables the identification and assessment of political options for solution pathways towards system transformation, using the identified principles and concept of levers discussed in this chapter as a baseline analytical, rational, and systemic approach within the GEO-7 assessment.

Appendix 12.1 Definitions of system transformation and transformative change in global environmental assessment reports

	Definition	Reference
IPBES	Transformative change is] a fundamental, system-wide reorganization across technological, economic and social factors, including paradigms, goals and values.	IPBES 2022, p. 544
IPCC	Transformative change: "A system-wide change that requires more than technological change through consideration of social and economic factors that, with technology, can bring about rapid change at scale."	IPCC 2022a, p. 2925
IPCC	Transformation pathways: "Trajectories describing consistent sets of possible futures of greenhouse gas (GHG) emissions, atmospheric concentrations, or global mean surface temperatures implied from mitigation and adaptation actions associated with a set of broad and irreversible economic, technological, societal, and behavioural changes. This can encompass changes in the way energy and infrastructure are used and produced, natural resources are managed and institutions are set up, and in the pace and direction of technological change."	IPCC 2022b, p. 1811
United Nations	"Transformative change will mean harnessing bottom-up social, technological and institutional innovation, including Indigenous Knowledge and creativity at the grassroots level and in the informal sector, particularly – but not exclusively – in developing and emerging economies. … Transformative change also requires the reconfiguration of social practices, social norms, values and laws that promote unsustainable or discriminatory behaviour and choices …"	United Nations 2019, p. 35
EEA	Transformative change, key features: "Alignment of social and environmental challenges with innovation objectives"	EEA 2019, p. 384
FAO	"Transformational change in land use and climate change is characterized by: (i) processes that moves away from the current regime of unsustainable land use, maladaptation and unmitigated greenhouse gas emissions, opening pathways to reverse these outcomes and work towards a sustainable planet (ii) being achieved through sustained changes that accept complexity and uncertainty (iii) a focus on root causes and nurturing relationships between scales and dimensions of change (e.g. organizations, markets, technologies, power and social relations, and ideas) (iv) being based on participation, equity and transparency (v) being supported by knowledge and data used for understanding, evaluation and course corrections"	FAO 2021, p. 8

Chapter summary

Credit: leungchopan/Envato

Global decision makers need a systemic approach to address the global environmental crises of climate change, biodiversity loss, land degradation and desertification, pollution and waste, and their intersections. The economic and financial, energy, food, material resources and environmental systems driving these environmental crises are interconnected and therefore require integrative and systemic transformation. Such a transformation of the current systems would alleviate their adverse effects on the environment and the human population, while further improving their sustainability and resiliency to future shocks and disruptions. The transformation needs to effectively integrate, among other factors, knowledge about climate change, including scenarios, trajectories, and adaptation options. This chapter proposes a 7-step methodology to guide such a system transformation {13.8}.

The proposed methodology addresses a pressing policy need to accelerate the pace of change *(well established but incomplete)*. It supports a paradigm shift from evolution to transformation, at a time when environmental crises are deepening, in part because past methods have failed to yield the desired results. These past failures have been tied to a lack of strong institutions and legislation, insufficient financial resources and infrastructure, weak enforcement capacity, difficulties in changing habits, values and lifestyles towards sustainable consumption patterns, and vested interests {13.2.1,13.2.2}. Breaking away from the past, this chapter presents a new framework for designing and implementing interventions to drive system transformations. Developing transformative solution pathways requires fundamentally new ways of thinking and acting. For this reason, operational steps for the roll out of solution pathways were developed, based on theoretically grounded requirements for system transformation (12.3). This framework is designed to be future-proof, anticipating challenges, complexities, and the implications of system transformations.

This 7-step methodology is adaptive and integrates interdependencies – synergies and trade-offs – between and within systems. Through an iterative, holistic decision-making process, it attends to the possible effects of resistance, shocks and risks, and provides guidance in designing transformative solution pathways. It is organized to identify the system goals, solutions, levers, actors, and actions to be taken. **Figure 13.1** illustrates how principles and steps are jointly articulated to serve these purposes {13.6}.

The proposed methodology accommodates operational environment uncertainty. Given the current global instability and the decline of democratic institutions, the governance of system transformations cannot rely unconditionally on strong institutions, democracy, stable economies, and peace. Systems transformations must be able to operate under shocks and crises {13.2}.

The methodology underscores the benefits of action, which largely exceed the costs of inaction *(well established)*. The costs of inaction in addressing the climate change, biodiversity loss, land degradation and desertification, and pollution crises are immense. Without accelerated mitigation efforts, such as the rapid deployment of offshore wind farms, and adaptation measures, such as fast-tracking a programme to retrofit cities with nature-based solutions against floods, the world is on track to breach the temperature limits set by the Paris Agreement. Global gross domestic product (GDP) is likely to decrease by 2.6 to 4.2 per cent by 2050 in pathways that fail to limit warming to 1.5°C above pre-industrial levels. Air pollution is responsible for approximately 6.7 million premature deaths annually, with annual health costs of around 6.1 per cent of global GDP. Global land degradation continues unabated and is estimated to cost more than 10 per cent of the annual global GDP in terms of the loss of biodiversity and ecosystem services. While there are winners and losers in any system transformation at different temporal scales, society as a whole will benefit in the long-term more from transformation than not. This methodology addresses the complexity of the actors involved and strives to ensure that no one is left behind {13.2, 13.8.7}.

The methodology links theory to practice *(well established)*. It does so by linking the six principles outlined in the theory chapter to the 7-step methodology clustered into three groups that closely match the three phases of the X-curve (**Figure 13.2**), that is, activation, acceleration, and completion of the transformation, and the seven steps in the Goal-Solution-Lever framework. Specifically, the first phase in the X-curve, where levers are activated and barriers to transformation are removed up to a tipping point, is linked to the methodology's cluster of levers/actions/actors (L) that activate the transformation process. The second phase in the X-curve of transformation, where positive change is accelerated and the old system breaks down, is linked to the methodology's cluster that is about finding solutions (S). It includes a turnover point when the new system overtakes the old. The third phase in the transformation, which is about the stabilization of the new/phase-out of the old system, is linked to the methodology's steps that are about setting goals (G). Ultimately, the methodology links a theoretical understanding of the transformation process to the practical design of solution pathways that accelerate sustainable systems and destabilize unsustainable ones. In particular, it shows how transformation is activated by a systematic inventory of solutions from multiple and complementary sources, and it specifically informs the activation of the process with the full range of possible levers, actors, actions and their interactions {13.3, 13.6, 13.7, 13.8}.

The methodology recognizes interdependencies across systems and interactions within systems *(well established)*. The sustainable development goals (SDGs) are by nature designed for systemic interactions. Integrating these interactions – including trade-offs and co-benefits – in policymaking can reduce costs by selecting the most efficient policy options, in which trade-offs are minimized, and co-benefits are maximized. For example, making renewable energy accessible to all can help alleviate poverty as a co-benefit. We make interdependencies a central element in our methodology. We consider within-system interactions in the selection of actions and solution pathways. Yet we also consider interdependencies across systems, with vicious cycles or trade-offs having a destabilizing effect and virtuous cycles or co-benefits a reinforcing one {13.4, 13.5, 13.8}.

The methodology facilitates systemic planning by addressing all aspects of a system's complexity *(well established)*. It helps plan differently, in ways that are systemic, holistic, adaptive, multi-scalar, multi-temporal, and inclusive. Systemic and holistic planning means recognizing current environmental crises as multidimensional and interconnected. Adaptive planning means anticipating and nimbly addressing

the likely resistances and new challenges throughout the implementation phases of the solution pathways; multi-scalar planning connects local actors to global actors and their institutions, and multi-temporal planning recognizes the need to address short- and longer-term processes. Finally, inclusive planning means reconciling the contributions, competing interests, and diverse views of multiple actors in society, including Indigenous Peoples, local communities, vulnerable populations, and the younger generation. This implies incorporating those actors in the co-creation and use of knowledge {13.6, 13.8}.

The methodology recognizes the contribution of Indigenous Knowledge and Local Knowledge, as well as their own decision-making practices in understanding and addressing environmental challenges *(well established)*. The solution pathways for transformation require consideration of the specific knowledge, worldviews, values, ethics, and long-term practices of Indigenous Peoples and communities which have a historical connection with place and nature. Indigenous Peoples govern formally or customarily at least a quarter of the world's terrestrial surface. When designing solutions for system transformation, it is essential to respect their territorial rights, values and practices {13.4}.

The methodology embeds adaptivity to future-proof transformation pathways against unexpected shocks *(well established)*. Our ensemble of solution pathways is geographically nuanced and is not expected to remain static. It is designed to be flexible and adaptive, allowing for adjustments if the problem to be solved becomes more complex over time or if unexpected shocks and crises arise. For example, agricultural intensification was the model implemented in many countries in the past to increase productivity and feed a growing population. The concept of food security, however, has since evolved beyond intensification towards quality, affordable and nutritious food for all, while conserving soil and the environment. Intensification alone, with the use of pesticides, fertilizers and mechanization, is no longer enough to address the complex food challenges of today. Transforming the food system in the 21st century requires seeking new solution pathways that address a complex set of interdependent challenges. Transformative solutions also consider the accelerating adverse effects, risks, and adaptation needs associated with climate change {13.8}.

The methodology proposes a sequential but adaptive 7-step process. It includes setting goals, reviewing past solutions, identifying the set of solution pathways to be designed, evaluating the identified solutions considering the local context, defining the combination of levers, identifying the options for short- and medium-term actions, and defining actors, their roles and interactions. The 7 steps have an integrated time sequence: as challenges change, the solution pathways adapt to the new realities, ensuring that goals are attained. The inclusion of adaptable responses to shocks of any sort, for example, pandemics, conflicts, economic, and environmental, must be part of the design of the solution pathways {13.6, 13.8, 13.9}.

The methodology proposes a built-in process of continuous evaluation *(well established)*. The methodology begins with a rigorous ex-ante evaluation of solutions, based on the 6 principles (Chapter 12), and integrates monitoring and evaluation throughout the process, allowing for the necessary changes to achieve the proposed goals. Policy makers are invited to test their ensemble of solution pathways ex-ante in order to future-proof them against shocks and anticipate the need to make changes during the process. For instance, the COVID-19 pandemic severely affected the world economy, significantly slowing down progress towards the SDGs. Other shocks for which an adaptive methodology is needed include the increased intensity and frequency of climate extremes that continue to affect billions of people globally with recurrent hazards {13.5, 13.6, 13.8, 13.9, Appendix 13.1}.

The proposed methodology is applied in Chapters 14–18, which focus on economics/finance, materials and waste, energy, food and environment *(well established)*. It is also applied to transforming the way the environment is managed to create resilient environmental systems for nature, energy, food and materials. The goal is to demonstrate how these systems can be transformed simultaneously while leveraging synergies and minimizing unintended consequences {13.8, 13.9}.

13.1 Introduction

This chapter proposes a methodology for solution pathways towards transformation designed to structure the report's progression from theory to solutions. It serves four main purposes, namely to: a) guide the subsequent systems chapters' efforts to identify viable pathways to transformation; b) build consistency across system chapters in their identification and description of solutions; c) link the proposed solutions to the theory of transformation, based on the 6 principles, outlined in Chapter 12; and d) support policy makers in building their own solution pathway in a specific context.

Abstracting from its details, the X-curve presented serves as a visual model of the transformation processes for raising desirable systems and destabilizing undesirable ones. It breaks down the transformation process into three stages, namely: activation, take-off (metamorphosis), and completion. For the sake of consistency, this three-stage description of theory is also adopted in the description of the methodology. Thus, in linking transformation theory to solutions, this methodology is built around these three stages of transformation:

- Stage I – referred to as the Levers, including the conditions, levers, and actors
- Stage II – referred to as the Solution, is about the form, momentum, and pace of transformation
- Stage III – referred to as the Goal, is about the outcomes of the transformation.

This framework is used to discuss not only the key steps but also the tools and basic principles to follow in designing a viable solution pathway (13.8).

The rest of the chapter progresses as follows. Key concepts and processes, including solution pathways, levers, actions, and policies, are defined. Then the methodological framework, specifically how the steps, tools, and common principles are considered in the design of solutions, is presented and discussed. This is then followed with a stage-by-stage description of the 7-step methodology. The first stage receives the most extensive discussion, especially in reviewing the key actors, levers, and enabling conditions. Specific examples are provided, including international successes and failures, and their contextual conditions. Evaluation criteria are provided in the last methodological step, to

assess whether a solution pathway is plausible, feasible and effective, meaning it will accomplish the proposed goals. This ex-ante evaluation will assess the solution's capacity to deliver results and to navigate the social, political, economic, and technological tensions and trade-offs expected.

In order to establish the 7-step methodology and how actors, levers, solutions, and actions interplay, certain foundational assumptions must be laid out to facilitate the logical flow of this chapter. Among these, adoption and uptake mechanisms are reviewed, including the costs of inaction and the benefits of action. By costing some of the global environmental crises, and putting a monetary value on them, awareness can be raised among actors and policy makers, strengthening the commitment towards transformative change. Finally, having a clear vision of policy effectiveness is also key to looking back at policy implementation mechanisms to identify opportunities for improvement and lessons learned.

Changing people's perceptions, attitudes and value preferences towards the environment and development is key to inducing a transformative change that achieves both the sustainable development goals (SDGs) and the internationally agreed global environmental goals (Sunstein and Reisch 2014; Blackenberg and Alhusen 2019; Haddock, Thorne and Wolfe 2020; Sockhill et al. 2022; Verplanken and Orbell 2022). However, it is important to note that behavioural change cannot happen overnight, and lasting behavioural changes take time (Bhandari 2023; Merz et al. 2023). Current environmental and development policies primarily focus on market-based values, neglecting other values such as relational, intrinsic, and non-market instrumental values (Pascual et al. 2023). Cultural values and cultural heritage must be an integral part of the transformation process, requiring special attention and prioritization (United Nations Educational, Scientific and Cultural Organization [UNESCO] 1972; Nocca 2017; Seekamp and Jo 2020; Fusco and Vecco 2021;). Understanding the diverse values of nature, including those promoted by Indigenous philosophies, the ecocentric approach, and incorporating them in decision-making will lead to better outcomes for nature and the environment (Pascual et al. 2023; Kopnina et al. 2024). Promoting empowerment, gender equality, and both inter- and intra-generational equity can help to expand people's choices and achieve sustainable development (United Nations Development Programme [UNDP] 2011).

13.2 Background

13.2.1 The causes for failed transformation

According to the United Nations (2023b), after 8 years of implementation, only about 15 per cent of the SDG targets are on track, approximately half show some progress while being moderately off track, and more than 30 per cent have not progressed or have even regressed below the 2015 baseline. The SDGs trailing behind include environmental goals such as SDG 6 Clean water and sanitation, SDG 12 Responsible consumption and production, SDG 13 Climate action, SDG 14 Life below water and SDG 15 Life on land (United Nations 2023b). The main causes identified are a lack of strong institutions, legislation and infrastructure, weak enforcement capacity, ingrained habits and lifestyles that are resistant to sustainable consumption, and vested interests (Filho et al. 2023a; Malekpour et al. 2023; Klees 2024). In terms of finance, there are still limited applications and efficient mechanisms to promote private investment, such as green credit, bonds, carbon markets, and biodiversity offset (Deutz et al. 2020; Finance Earth 2021; United Nations Environment Programme [UNEP] 2021; Caldwell, Alayza and Larsen 2022). The distribution of international official support in many cases is uneven. It usually gives less priority to natural resources use, environmental pollution, and climate change, regardless of the vulnerability of the recipient country (Massa and Díaz 2023), and it is unequally spread among developing countries (Rickman et al. 2022).

Other barriers include challenges in mobilizing collective action, trade-offs between goals, difficulties in establishing accountability and commitment, lack of technology and data, implementation capacity, and policy actors operating in silos (Filho et al. 2020; Moors et al. 2022). Gender inequalities also have adverse effects and are a major impediment to the achievement of the SDGs (Filho et al. 2023b; Jeevanasai et al. 2023). In addition, the confluence of the COVID-19 pandemic, regional conflicts and wars, rising inflation and living costs, and natural disasters further exacerbated the slow implementation of the SDGs (Filho et al. 2023a; Malekpour et al. 2023; United Nations 2023b).

The Global Sustainable Development Report (United Nations 2023b) report and related studies found that to achieve the SDGs, it is necessary to carry out holistic

system transformations enabled by governance, economy and finance, individual and collective action, science and technology, and capability actions (Moors et al. 2022; United Nations 2023b).

13.2.2 The need for urgent action and accelerated change

The costs of inaction in addressing the rising emissions exacerbating climate change, as well as the continuous loss of soil and biodiversity, have reached an alarming rate as shown in Chapter 4. While the effect of economic growth on environmental degradation is established, recent studies (Acheampong and Osei Opoku 2023) show that environmental degradation significantly slows economic growth, mainly through effects on health, foreign direct investments and technological innovation. The costs of inaction in addressing the global environmental crises are incalculable. Without accelerated mitigation efforts, the world will breach the temperature limits set by the Paris Agreement. Global GDP is likely to decrease by 1.3–2.7 per cent by 2050 in pathways that fail to limit warming to 2°C, and 2.6-4.2 per cent in pathways that fail to limit warming to 1.5°C above pre-industrial levels (Intergovernmental Panel on Climate Change [IPCC] 2023a; IPCC 2023b). This, combined with biodiversity loss, will make us more vulnerable to disasters and weather extremes as well as jeopardizing human well-being and achievement of the SDGs (Nabuurs et al. 2023). Climate change leads to disproportionate adverse effects on women, youth, the rural poor, and Indigenous Peoples (Food and Agriculture Organization [FAO] 2024; Filho et al. 2021; Reyes-García et al. 2024). A survey of rural households in 24 low- and middle-income countries from the five world regions notes that heat stress widens the income gap between female-headed and male-headed rural households by US$ 37 billion a year, and floods by US$ 16 billion a year (FAO 2024). Only 1–6 per cent of the 4,164 climate actions in these countries were focused on women, youth and the rural poor, which highlights the need for more climate action programmes that specifically cater to women, youth and the impoverished. The cost of

Credit: wirestock/Envato

air pollution is vast, with estimates suggesting that air pollution is responsible for approximately 6.7 million premature deaths globally every year, entailing annual health costs of around 6.1 per cent of global GDP, equivalent to more than US$ 8.1 trillion in 2019 alone (World Health Organization [WHO] 2023). An estimated 400,000–1,000,000 people die every year due to plastic pollution and other mismanaged wastes (Tearfund 2019). Approximately 100,000 marine mammals and 1,000,000 sea birds die every year for the same reason (Darrah 2023; Ocean Blue Project 2021). Global land degradation is estimated to cost more than 10 per cent of the annual global GDP in terms of the loss of biodiversity and ecosystem services (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2018).

The benefits of action generally exceed the costs of inaction (Global Commission on Adaptation [GCA] 2019; IPCC 2023b; International Union for the Conservation of Nature [IUCN] 2020; Nabuurs et al. 2023; UNEP and Food and Agricultural Organisation [FAO] 2020; UNEP 2021; IPCC 2023c; Verdone and Seidl 2017). The global economic benefits of climate mitigation exceed the cost of mitigation (IPCC 2023b; Nabuurs et al. 2023; IPCC 2023c). Ecosystem restoration of 350 million hectares of degraded lands by 2030 is projected to yield ecosystem benefits worth over US$ 9 trillion for an investment of US$ one trillion or about 0.1 per cent of global GDP, that is, a benefit-cost ratio of 9:1, plus the removal of an additional 13–26 gigatons of greenhouse gases (GHGs) from the atmosphere (Verdone and Seidl 2017; IUCN 2020; UNEP and FAO 2020; UNEP 2021). The health co-benefits of reducing GHGs and air pollutants are estimated at US$ 54 trillion compared with global costs of around US$ 22 trillion (UNEP 2019). According to another UNEP report, the annual social and environmental costs of plastic pollution are projected to be from US$ 300 billion to US$ 600 billion per year, with some estimates as high as US$ 1.5 trillion per year (UNEP 2023). The report states that shifting to a circular economy and relying on the 3R strategy – Reuse, Recycle, and Reorient – and diversification, as well as tackling the legacy of plastic pollution, could lead to an 80 per cent reduction in plastic pollution, a net increase of 700,000 jobs by the year 2040, as well as improving livelihoods and encouraging innovation. Apart from reducing annual GHG emissions, it could lead to savings of US$ 1.3 trillion in direct public and private costs over the period 2021–2040 and avoid US$ 3.3 trillion of environmental and social costs due to plastic pollution. Another report notes that investing US$ 1.8 trillion globally in five areas – early warning systems, climate-resilient infrastructure, improved dryland crop production, global mangrove protection and making water resources more resilient – over the period 2020–2030 could generate US$ 7.1 trillion of total net benefits, a benefit-cost ratio of 3.9:1 (GCA 2019). A scenario analysis of plausible plastic futures up to 2060 suggests that a global action scenario with stringent policies implemented worldwide would likely reduce plastic waste by a third, almost eliminating plastic leakage into the environment while lowering global GDP by about 0.8 per cent (Organisation of European Co-operation and Development [OECD] 2022). However, this likely decrease in global GDP overlooks the tangible and intangible benefits of the avoided damages caused by plastic pollution.

13.3 Evaluation of theories of development and environmental change and embracing complexity

Over the last couple of decades, a renewed focus on system transitions and resilience thinking has brought the scholarship on systems thinking to the forefront of efforts to embrace complexity (Chapter 12). Classic theories on economy, society and the environment are no longer viewed as appropriate in addressing the complexities of today's world. New theories to address these challenges must cover multi-dimensionality, multi-actor perspectives, uncertainty and non-linearity of system dynamics. Recent theories on system transformation already capture these principles, but the methodologies and methods to guide system transformations lag behind. The operationalization of system transformations requires carefully designed transformation processes that consider multi-actor perspectives, are socially acceptable, politically, economically and financially feasible, consider equity, distribution and diversity impacts, and pay special attention to the effects on Indigenous Peoples as well as local communities. Step-by-step methodologies that can guide decision makers to operationalize the transformation processes are very much needed.

13.4 Incorporation of Indigenous Knowledge and Local Knowledge

The contribution of Indigenous Knowledge and Local Knowledge to understanding and addressing environmental challenges is increasingly acknowledged

Credit: emirkoo/Envato

(Brondízio et al. 2021), and these types of knowledge are now included in global assessments, such as IPCC and IPBES (Tengö et al. 2017). Based on a recent review of the literature, Brondízio et al. (2021) identify 6 pathways through which Indigenous Peoples and other societies with deep historical connections to place engage with the management of and relationships with nature. These pathways include:

- territorial management practices and customary governance
- nature conservation and restoration efforts with regional to global implications
- knowledge co-production for assessments and monitoring
- countering the drivers of unsustainable resource use and resistance to environmental injustices
- role in environmental governance across scales
- and alternative conceptualizations of the interrelations with nature.

The solution pathways for transformation require consideration of Indigenous Peoples and other societies with deep connections to nature's specific knowledge, worldviews, values, and perspectives on desired futures (IK&LK Dialogues 2025). Most Indigenous cosmologies do not consider nature as separate from humans and promote values of reciprocity and care in relationships with non-humans (Brondízio et al. 2021; IK&LK Dialogues 2025). In all systems, Indigenous Knowledge and Local Knowledge is a crucial solution lever. The role of Indigenous women in climate change adaptation and environmental sustainability is highly recognized. They are often at the forefront of defence, adaptation, and transformation initiatives, leading community-driven projects and movements (Singh et al. 2022; Yadav and Shekhawat 2024). The importance of Indigenous Knowledge and Local Knowledge is evident in environmental and energy systems (IPBES 2019a; Estrada et al. 2022; Pörtner et al. 2022), in the transformation of the food system (Argumedo 2021), or in waste management (Madonsela, Semenya and Shale 2024). Indigenous Peoples account for 6.2 per cent of the global population (estimation of International Labour Organisation [ILO] 2020 p. 52), govern either formally or customarily at least a quarter

of the world's terrestrial surface (Garnett et al. 2018) in 90 countries and also monitor 80 per cent of the world's biodiversity (Convention on Biological Diversity [CBD] 2022). The good-to-moderate condition of 92 per cent of native lands shows a solid understanding of ecosystem management (Das et al. 2022; Garnett et al. 2018; Sangha et al. 2025). When designing solutions for system transformation, it is essential to respect their territorial rights, values and practices. Approximately 60 per cent of Indigenous Peoples' land in 37 countries is at risk due to the conversion of Indigenous land for industrial development, according to Kennedy et al. (2023). Against this background, solutions for system transformation cause more environmental and human crises if their potential negative effects are not considered. Supporting Indigenous Peoples' rights, self-determination, sovereignty and leadership is crucial, as demonstrated in projects related to energy system transformation (Zárate-Toledo, Patiño and Fraga 2019).

13.5 Policy effectiveness, coherence and decision-making

13.5.1 Policy effectiveness

The Sixth Global Environment Outlook (GEO-6) report found that the reduction of substances that deplete the ozone layer, the control of persistent organic pollutants, and the restrictions on the transnational transportation of hazardous waste have been effective policies (UNEP 2019). However, environmental policy decisions are often made in response to environmental problems, rather than taking proactive action to resolve the root causes and drivers of environmental issues (UNEP 2019; Jacob and Elkins 2020; Global Young Academy 2024). The concept of "grow first, clean up later" is still ingrained in most countries' development models and sectoral policies. It was concluded that to achieve most international agreed goals, profound systems transformations are required.

Policy plays an important role in the transformation process because of its governance function (Jacob and Elkins 2020), and transformation is usually the result of policy changes in different fields and at different levels (Berglund et al. 2022). To initiate the policy approach for transformation, it is necessary to create a knowledge base about transformation, enabling conditions for innovation and introducing experimental regulations. A vision of the shape and configuration of the new system needs to be established in order for policy to be developed and institutional reforms to be implemented. This enables different actors to deploy innovation as well as to eliminate the current system (Jacob and Elkins 2020; Independent Group of Scientists appointed by the Secretary-General, 2023; Global Young Academy 2024). Additionally, it is essential to identify winners and losers, involve them in the process, and address the barriers (López-Avilés et al. 2015). Furthermore, gender equality is critical to achieving sustainable and equitable development goals; therefore, it should be integrated in the policy design and implementation (UN Women and UNDP 2018; Filho et al. 2023b).

To achieve transformation, a package of policy instruments is often needed, which can achieve the goals that one single instrument cannot, improving the effectiveness of each individual instrument while minimizing undesired consequences. To design such a package, central and supporting instruments must be identified and their interrelationships must be considered, including preconditions, synergies, and facilitating or hindering conditions. The choice of policy instruments should be based on financial, technical, and technological feasibility, as well as preconditions, political legitimacy, institutional settings, and social acceptability, and it depends greatly on the specific context and conditions of each country (Matt et al. 2013). Some of these factors are typically the result of the ex-ante policy assessment, which sometimes employs models and techniques in the policy formulation process.

13.5.2 Policy coherence

The proper design of policies is critical for ensuring policy effectiveness. This means choosing the right mix of policy instruments and building an enabling environment and governance structures. This also means adhering to all phases of the policy cycle – agenda setting, policy design, policy implementation, and policy review – and policy coherence, as well as including an assessment of social, environmental and cultural impacts (Ferrier et al. 2016; UNEP 2019; Ninan 2020). Policy coherence is a crucial lever for achieving systemic transformations to reach the internationally agreed environmental and development goals. It refers to an effective alignment of various policies so that efforts in one policy area do not undermine

efforts in another, and if possible, even reinforce these efforts (Parsons and Hawkes 2019 cited in OECD 2021). This requires wide participation and inter-sectorality in policy design. The SDG target 17.E focuses on enhancing policy coherence for sustainable development. The OECD introduced the concept of policy coherence as an approach to systematically integrate the economic, social, environmental, and governance dimensions of sustainable development into policymaking, ensuring that they are mutually supportive (OECD 2015). A UN report emphasizes that "governments will need to prioritize policy coherence, overcome sectoral silos and align existing rules and regulations towards achieving the SDGs that are interlinked across sectors" (United Nations 2019). The whole-of-government approach seems suitable for overcoming sectoral silos. Policy coherence implies that policies should be aligned across scales, sectors and policy communities. Effective and inclusive governance mechanisms are required to address policy interactions across sectors and align actions between different levels of government (OECD 2021).

The synergies and trade-offs between different policies, as well as their transboundary effects, need to be analysed. To address the global environmental crises, it is necessary to design and select policies and instruments that yield win-win outcomes, employing an integrated approach. If trade-offs between different policy interventions cannot be reconciled, decision makers should rely on an inclusive and participatory process involving different stakeholders, including marginalized and vulnerable sections, and women, keeping in view the government's policy priorities, with special attention to environmental variables and nature-based solutions. Decision makers should assess the gains or losses of alternative solution pathways, as well as the political and societal acceptance of the intended policy interventions. Involving women in climate action and decision-making processes will help address these disparities and leverage their unique perspectives and knowledge, leading to more effective solutions.

13.5.3 Decision processes

Tools and techniques for effective and robust decision-making are improving thanks to steady developments in decision sciences (Jones et al. 2014; New et al. 2022). There are many decision-analytic methods and approaches to choose from, including Bayesian, interval methods, decision-making under deep uncertainty, cost-benefit analyses, multi-criteria decision analysis, elicitation, and general decision support tools. Multi-attribute decision-making is particularly intriguing because it offers a complete and methodical approach, such as for energy system transformation pathways. It allows for the consideration of public opinions in the decision-making process and the involvement of stakeholders (Hoek et al. 2021; Hottenroth et al. 2022). Iterative decision-making processes for solution pathways that incorporate recursive and reflexive steps help avoid linearity. Model validation, verification, and data interpretation are considered essential. The iterative decision-making process requires careful implementation, monitoring, evaluation and risk management. Iterative decision-making is context-specific and can take into consideration socioeconomic, political, cultural, and conflict-sensitive situations, as well as hazards and risks caused by modifications to the bio-physical environment (Jones et al. 2014; New et al. 2022). Combining new knowledge and technological advancements through iterative decisions enables the analysis of their effects on the environment, society, and the economy. The literature shows that ensuring strong governance grounded in local contexts, providing medium- and long-term support, including diverse knowledge systems – Indigenous, local, scientific, and citizen – in processes of knowledge co-production (Hill et al. 2020), processing technological innovations, and ensuring appropriate financing are necessary conditions to successful outcomes (Jones et al. 2014; New et al. 2022). It is important to consider local and Indigenous decision-making processes that are context specific. The decision-making process can be top-down or bottom-up, and is often a combination of both, involving multiple actors in the implementation steps (Petzold et al. 2023).

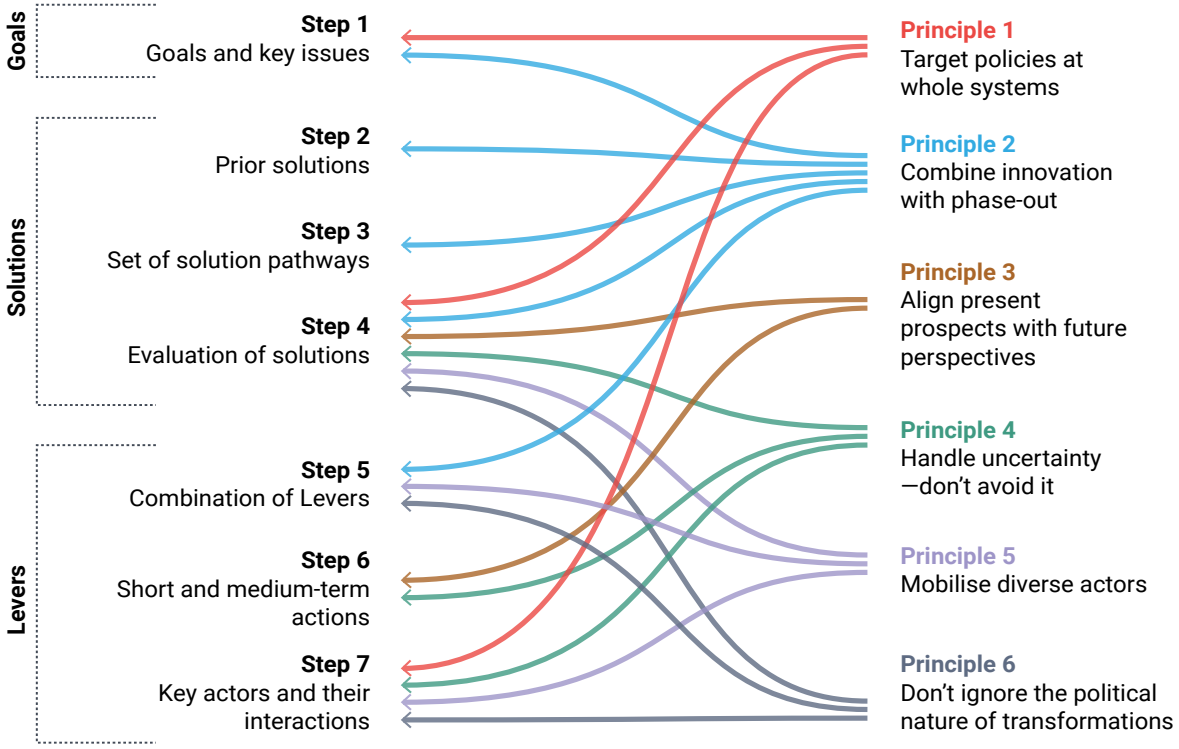
13.6 Presenting the 7-step methodology

13.6.1 Why is a new methodology needed?

As already discussed, previous solutions for agreed international goals have not delivered the desired results. With the environmental crises worsening, the global community needs to act urgently to accelerate the pace of change, from evolution to transformation. Policymakers must think differently and act systematically and holistically because the current

crises are multiple and interlinked, otherwise known as polycrises. Action must adaptively address resistance and shocks, in multi-scalar ways that connect the local and the global, the individual and society. Theories of development and environmental change increasingly embrace a systems perspective, and methods must incorporate diverse forms of knowledge, including Indigenous Knowledge and Local Knowledge.

13.6.2 What does the methodology do?



The new methodology innovates by integrating new theoretical development and contexts, for instance, shocks such as the recent pandemic. It clearly links the theory of transformation to practice, that is, the tools for finding and implementing solutions. It produces an explicit 7-step approach, theoretically based on the six principles developed in Chapter 12, to identify effective pathways towards transformation. It guides the clear and comprehensive specification of goals and the systematic identification of levers, actors and actions to be undertaken. It steers the systematic inventory of solutions from a mix of sources, including modelling exercises, past initiatives, and Indigenous Knowledge and Local Knowledge. It conducts the rigorous ex-ante evaluation of these solutions. It integrates monitoring and evaluation throughout the process. It is solution-centred and recognizes the crucial interdependencies between and within systems. It fosters policy coherence and effectiveness by supporting bottom-up approaches, and highlights the cumulative benefits of immediate action, that is, the cumulative losses of inaction.

Figure 13.1 shows the relationship between the 7 steps proposed to design a solution pathway, and the six principles developed in Chapter 12. The figure shows small boxes that contain examples of questions the policymaker should ask to ensure the proposed solutions will lead to transformative change.

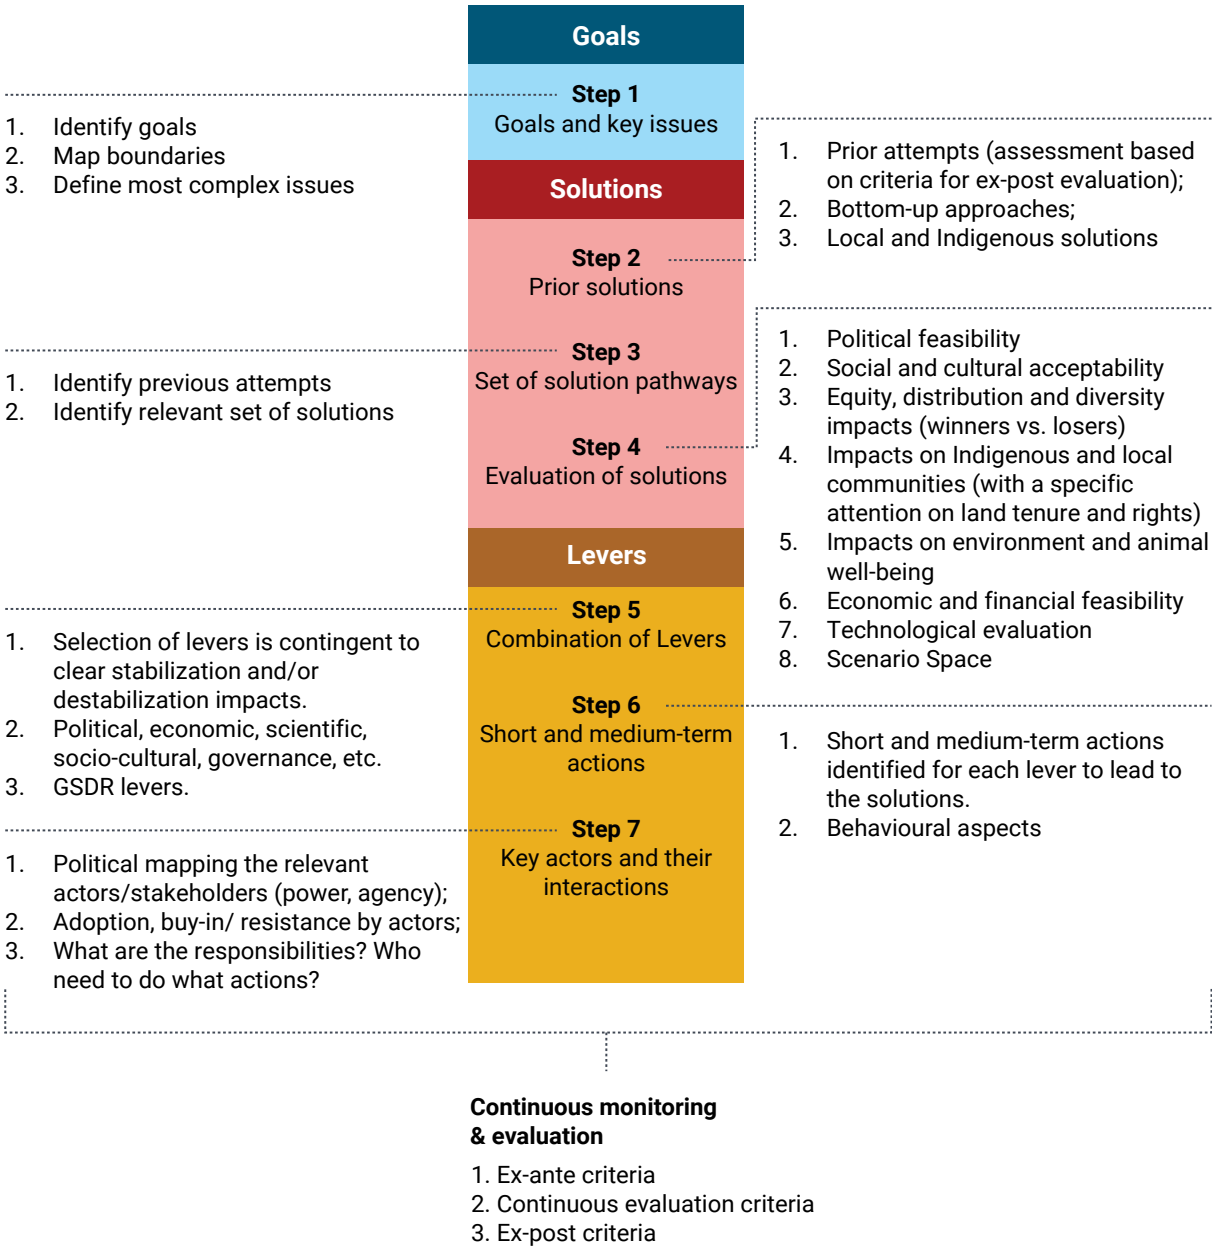
13.6.3 What are the expected outcomes with this methodology?

Planners can identify a robust set of solutions derived from multiple sources and fully vetted based on multiple criteria. Solutions are grounded in a better understanding and consideration of local contexts and competing interests. The methodology provides an understanding and visualization of a process towards

Figure 13.1: Bridging principles and action: aligning steps for effective system transformation

Note: this figure shows how the 7-step methodology integrates the 6 principles for system transformation into the development of solution pathways. Each step draws on a distinct set of principles to guide effective and coherent action.

achieving a future-proof goal of transforming systems.



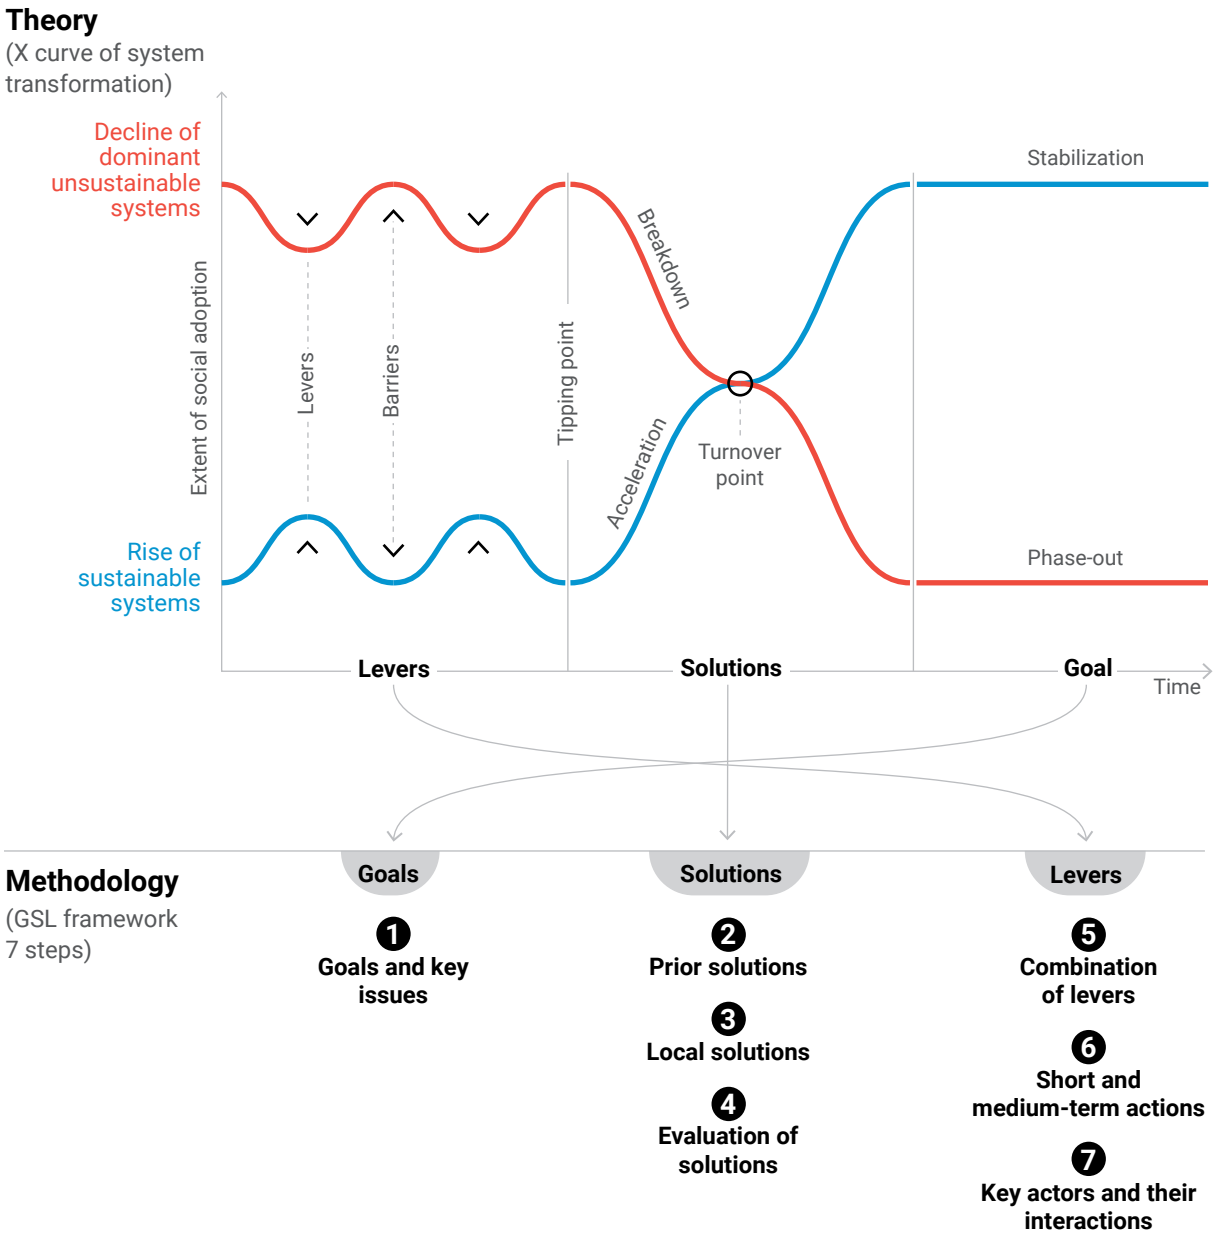
The methodology, made up of the 7 steps summarized in **Figure 13.2**, shows how it integrates the Goals, Solutions, Levers framework and the evaluation monitoring methodology.

13.7 Presenting the X-curve

The X-curve is a visual representation of a solution pathway for system transformation integrating the 7 steps, as well as the GSL framework, the evaluation, and the 6 principles (**Figure 13.3**) (Hebinck et al. 2022; Matti et al. 2022; Matti, Bontoux and Jensen 2025; Silvestri et al. 2022; United Nations 2023b).

The X-curve diagram uses the S-curve graph from the sixth Global Environment Outlook (GEO-6) report to show the greater impact on environmental sustainability of transformational actions or policies in comparison to integrated (environmental, economic, social) actions or policies, and business-as-usual actions or policies (Silvestri et al. 2022; UNEP 2019; United Nations 2023b). The sequencing of the steps is illustrated by the arrows and numbers for each action and shows the progress towards

Figure 13.2: Summarized 7 steps fit to the GSL, 6 principles and evaluation



transformation as the actions progress up the S-curve. At some point – likely a critical mass or broad adoption rate – these actions are no longer necessary and there is a self-sustaining momentum towards transformation.

The X-curve depicts both solution pathways intentionally steering systems towards a) a rise of sustainable systems, and/or b) a decline of unsustainable systems. The upwards and downward tipping points cannot be methodologically identified. Rather, it is within the contextual reality of a given system that the action exerting an upward or downward infliction can be identified.

The figure describes the transformation from theory to applied methodology. Mechanically, solution pathways are selected to gradually disrupt unsustainable systems and foster the rise of sustainable ones. The x-axis is defined as time clustered in three phases: Phase 1: Activation; Phase 2: Take-off; Phase 3: Stabilization and Phase-out. The dependent variable is defined as the extent of social adoption of the solution pathway. Phase 1 Activation involves a combination of stabilizing and destabilizing levers that support or inhibit the uptake of a solution. During the take-off phase, a set of solutions is being socially adopted and sustained over time, whereas solution pathways

Figure 13.3: Curve in relation to Goals-Solutions-Levers Framework

that are considered unsustainable are being broken down and ultimately phased out.

The Goals-Solutions-Levers diagram provides a tool for building the solution pathway at the system level. The exemplified frameworks show how to define a solution pathway in each system; the system transformation would unfold in order from Levers, to Solutions, to Goal. However, to define a solution pathway strategically, the system chapters defined the Goals, Solutions and Levers as suggested in the 7-step methodology. As shown in **Figure 13.3**, the GSL Framework is presented in reverse order in the X-Curve that represents the 7-Step methodology from theory to practice. Starting with the Goal in mind as Step 1, the decision maker develops a solution pathway in Steps 2–4, while considering a set of Levers with Steps 5–7. The steps are described in detail in the following section.

13.8 Step-by-step description of the 7 steps

13.8.1 Step 1. Identify goals and define the most complex issues for the system that need to be solved to achieve transformations and the specific transformational goals.

The processes of identifying goals for system transformation must follow good governance principles, including, inclusive and participatory decision-making, co-design and co-creation of solutions, accountability, and transparency. These principles also include the active involvement of diverse actors in the process of identifying the system goals and in envisioning the desired future. They further link to the governance targets of SDG 16 on "Peace, Justice and Strong Institutions" and a transformative promise of the 2030 Agenda "To Leave No One Behind (LNOB)" (United Nations 2023a).

Thus, the process for identifying goals should:

- Map out the boundaries of a given system (e.g. temporal, geographical, etc.).
- Clearly identify the problem that requires solving (tools such as SWOT and PESTLE analysis may be useful here)
- Develop an inclusive and empowering multi-actor consultation process for the relevant actors within a system.
- Use strategic foresight when possible (Matti et al. 2025).
- Through the consultation process, identify the most pressing issues/areas within a system that need urgent attention and action.
- As a result of the iterative consultation processes, develop a list of a set of goals to address the pressing issues and for system transformation.
- Work on detailed discrepancies, align the proper wording and targets with the involved stakeholders, ensuring stakeholder commitment to the goals.
- Identify interdependencies for trade-offs and co-benefits across goals, but more so across systems, and utilize the leveraging effect if applicable.

Goals can be understood across three levels:

- **Overarching goals level**
  These are aspirational and not necessarily directly attainable goals. Actions should nevertheless carry the transformational process towards that goal and allow major progress towards it, for example:
  Sustainable life on Earth is the most overarching goal encompassing most internationally agreed goals and inspiring the 2030 Agenda. It is clearly a foundational, universal and overarching goal.
  Halting climate change is not necessarily attainable at the local level, but local mitigation projects, emission reductions, and exiting a fossil-fuel economy can significantly help limit climate change.
- **System-level goals**
  These goals are partially attainable and can be achieved within a specific timeframe. For example:
  Enhance food systems with nutritious, healthy, and affordable food, while minimizing

environmental harm through humane and sustainable agriculture and land management practices.

- **Implementation-level goals**
  These are concrete, attainable goals with clear outcomes and measurable indicators. They operate at the country, policy, project, programme, or legislative level and contribute directly to system-level and overarching goals. For example: Ensure national compliance with the 30×30 biodiversity target, whereby at least 30% of terrestrial and marine areas—prioritizing key biodiversity sites—are effectively and equitably managed through connected conservation systems; and Enhance the state or health of forests through improving the richness of plant and animal species, ecosystem services, participatory management by local communities, and adaptive and sustainable management.

13.8.2 Step 2. Review sources of solutions

Review and identify one or more examples or evidence that illustrate prior attempts to transform these systems and analyse them according to ex-post criteria.

Some actions may have already been tried and they yield lessons to be learned. Analyse these examples based on the goal, design, involved actors, instruments, tools, and achieved output and outcome, using policy analysis to understand where they succeeded and failed. Analyse the stage of maturity: sustainability transitions, including system transformations, with a broader consideration of well-being beyond humans, that is, animal well-being and nature, which are long-term processes. It takes time to destabilize a system and develop an alternative one. The evidence can also be analysed to determine whether they are in the predevelopment, take-off, acceleration or stabilization phases, to avoid hasty judgements.

Use the examples to support the proposed sequencing and timing of the proposed actions in the solution pathways.

Activating an ensemble of solution pathways for transformation should address a system sustainability problem at a given point in time. However, if not adaptive, this ensemble of solution pathways can become inappropriate in solving a problem that becomes more complex over time. For example, agricultural intensification, such as India's Green Revolution, and the utilization of pesticides and chemical fertilizers was the model implemented in many countries to increase productivity and food security (Conway 1999); Conway and Barbier 1988; Ninan 1992; Ninan 2000; Pingali 2012; Conway and Barbier 2013; John and Babu 2021; United Nations 2023b). Food security, however, has expanded to encompass quality, affordable, and nutritious food for all, while also conserving soil and the environment. Intensification alone, with pesticides, fertilizers, and mechanization, has been superseded in addressing an increasingly complex challenge (Conway 1999; Duguma 2014; Nabuurs et al. 2023). Transforming the food system in the 21st century requires seeking new solution pathways that address a complex set of interdependent challenges. The 7 steps have an integrated time sequence to ensure that as challenges change, the ensemble of solution pathways adapts constantly to the new realities in order to ensure goals are attained.

Similarly, the electrification of vehicles today to support the net-zero goal by 2050 could be an oversimplification of the problem. Transformation should include changes in all mobility behaviours including car sharing, public transport, and the use of bicycles (International Energy Agency [IEA] 2023). Further, solutions are needed for the adequate management of electrification, battery waste disposal, and a plan to reduce the extraction of rare earth materials (Li et al. 2021; Jaramillo et al. 2023). Shocks of any sort must be considered when designing solution pathways. Adaptability that allows rapid shifts in the ensemble of solution pathways to achieve a given goal is central. Policy makers are invited to test their ensemble of solution pathways to make them future-proof against shocks and anticipate the need to make changes during the process. Such shocks may be related to health, the economy, or the environment. For instance, the COVID-19 pandemic severely affected the world economy, significantly slowing achievement of SDG targets (United Nations 2023b). The increased intensity and frequency of climate extremes affect billions of people globally with recurrent hazards. The ensemble of solutions must be adaptive to respond to these shocks while maintaining progress towards

Credit: ©UNEP

the goal. The disruptions, such as migration due to climate change, can also serve as an entry point and a valuable learning opportunity to reconfigure societal systems and guide societal transformations toward the desired state.

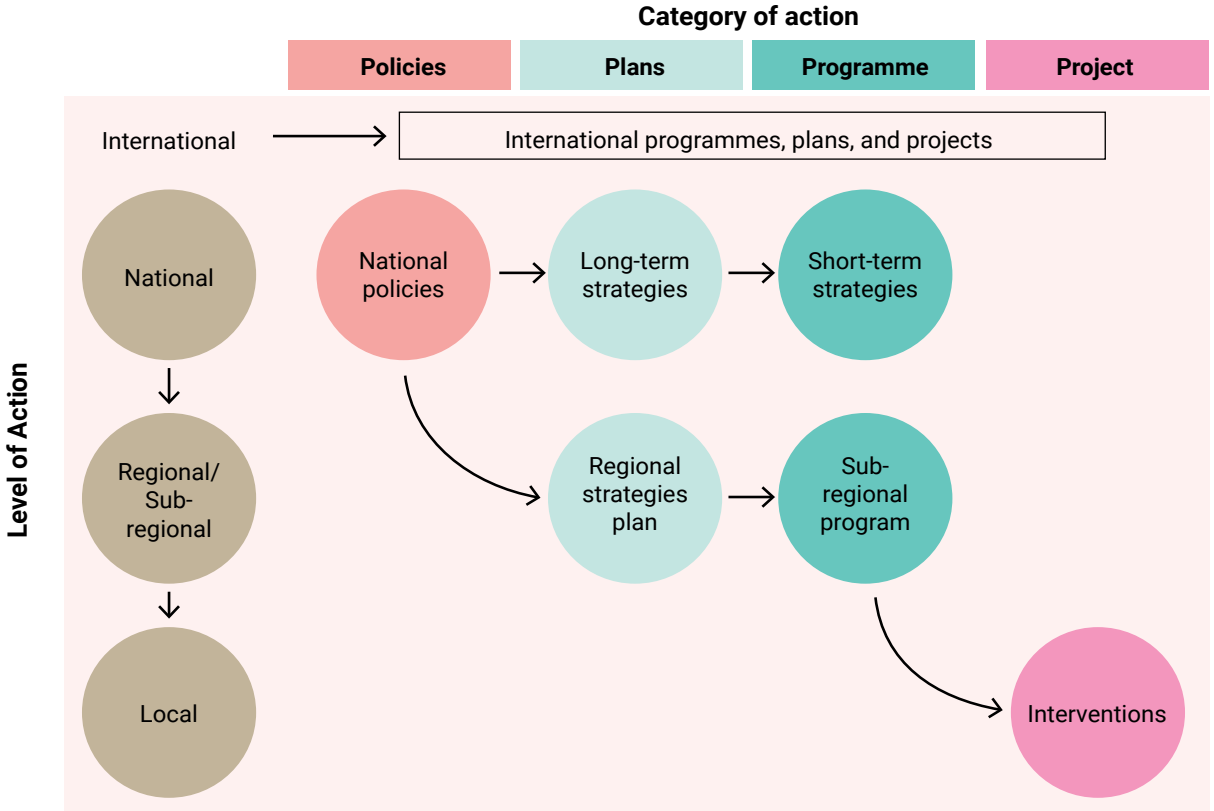
13.8.2.1 Bottom-up approaches and solutions

The lack of representation of bottom-up approaches in global sustainability trajectories and scenarios is well-documented (Vervoort et al. 2014; IPBES 2019b; Pereira et al. 2021). Yet they can improve the exploration of scenarios for future global sustainability. They might already be practised at a limited scale, but with proper structural support, such as legal and market support, they can be scaled up to the national and regional scales (Moore, Riddell and Vocisano 2015). Failure to incorporate bottom-up perspectives into global sustainability solutions may undermine their legitimacy and render them ineffective when implemented locally. To ensure the representation of bottom-up sustainability solutions in global scenario development, it is important to explore their inventory, to consider those that might already be practised by individuals, groups or communities, and to explore how they can be scaled up. For example, a town might extensively use nature-based solutions to deal with the problems created by stormwater. A village community can reorganize itself through a social innovation to deal with a local pressing environmental issue, such as forest fires in nearby forests. Or a group of farmers might practise regenerative agricultural practices that address food sustainability in the territory. These solutions could be totally new or based on the revival of traditional knowledge and practices within a given territory. They serve as an inspiration for devising solutions at the global system level.

13.8.2.2 Restructure the models of action and the role of actors

The results review of the effectiveness of previous systems transformation solutions identifies patterns of actions and the roles of actors as the reasons for the failure of previous solutions. This is due to decision-making, governance mechanisms and the performance of actors in the execution chain of solutions (Van Vuuren et al. 2015; Turnheim and Nykvist 2019). Action refers to the mechanisms and pathways for implementing the solutions advocated. These include, for example, strategic assistance projects – both financial and technical – to NGOs and other organizations. These projects are useful for protecting the most threatened ecosystems, implementing carbon tax policies, and providing monetary incentives that aggregate market signals

to enhance the greater attractiveness of carbon reduction options.



The main criticism is that effective actions must incorporate the key constraints that are most often overlooked. These include technological maturity, economic costs, infrastructure, operational and quality issues, the societal acceptability of each of the relevant technological pathways, and sociotechnical, political and cultural inertia (Clemens 2007; Haydu 2010; Haydu 1998; Mahoney 2000; Pettigrew 1997; Loftus et al. 2015). In this context, models of action should be more integrated and diverse, and reject cockpitism (Flanagan, Uyarra and Laranja 2011; Kivimaa and Kern 2016). They should focus on the governance of transition at multiple levels and scales (Nilsson, Hillman and Magnusson 2012; Raven, Schot and Berkhout 2012) and consider the multiple skills of decision makers.

This rejection of cockpitism avoids the illusion that only top-down leadership by governments and intergovernmental organizations can solve global problems (Hajer et al. 2015). It incorporates the role of other change actors, such as businesses, civil society and local authorities (Hajer et al. 2015), and other qualitative and societal aspects crucial to accelerate transition (Loftus et al. 2015). Thus, effective solutions encompass two main considerations, as follows:

- The levels of implementation of international, national, regional, or local actions according to the decision-making authority, which are the international groups, national or federal leaders, regional or state leaders, subregional or local leaders. Thus, for instance, municipal leaders may have a more or less central role, depending on national context. Indeed, strategies based on action models have been criticized for not sufficiently considering crucial aspects of governance, including the multiple levels and scales of governance involved in transitions (Nilsson, Hillman and Magnusson 2012; Raven, Schot and Berkhout 2012; Turnheim and Nykvist 2019).

- Categories of action: policies, plans, programs and projects (**Figure 13.4**). The effectiveness

Figure 13.4: Categories and levels of actions for changes

Sources: Authors, Turnheim and Nykvist 2019

Credit: YuriArcursPoepleimages/Envato

of a solution also depends largely on the type of action envisaged. Taking into account action categories makes it possible to consider the temporal sequencing of strategies – short, medium and long term – to achieve a given scenario (Nilsson and Nykvist 2016); the granularity of interventions, for example, policy combinations and the interaction of interventions (Flanagan, Uyarra and Laranja 2011; Kivimaa and Kern 2016; Rogge and Reichardt 2016); and the prioritization of resources mobilized (Tavoni et al. 2014).

These contextual and more realistic parameters determine why some solutions may be more likely to fail than others (Turnheim and Nykvist 2019)

13.8.3 Step 3. Identify a set of solutions for the system transformation and check their coverage

Solution are the way to achieve goals. Multiple solutions can contribute to achieving one goal. Solution pathways are collections of actions, sequenced and timed to achieve a particular solution, and that creates a self-sustaining momentum towards achieving recognized goals:

- Review the sources of solutions, for example, previous attempts to change the system, bottom-up approaches, and available solutions based on Indigenous Knowledge or Local Knowledge,
- Once the sources of solutions have been reviewed, list around 5–6 solutions relevant for the system that could lead to system transformation and achieve the identified goals.
- Describe the list of solutions in detail: Cross-check the coverage of these solutions against the modelling exercise (Chapter 11). For the solutions covered by the modelling exercise, draw insights in terms of quantitative projections, the specificities of a solution in terms of trade-offs, synergies, challenges and opportunities.

13.8.4 Step 4. Validate the identified set of solutions in a system context and scale (most relevant for policy makers)

Once the set of plausible solutions has been identified, their feasibility needs to be checked in a local context. Chapter 10 provides an overview of plausible solution pathways for transformation, and it can guide the choice of solutions to be identified here. The solutions include technological and behavioural solutions. These scenarios must link to a storyline reinforcing the scenarios and further justifying their connection with the goals. Thus, this validation of the solutions needs to adhere to the following checklist:

- **Political feasibility** – analysing to what extent implementation of the solutions will be politically accepted and carried out in the longer

term, avoiding incumbent or future actors' resistance to change.

- **Social and cultural acceptability** – gaining legitimacy for the proposed solutions through consent – that is, social processes through which an agreement is given to a certain phenomenon by stakeholders – is an important element in designing and implementing these solutions, to achieve collective participation in and ownership over transformations (Beetham 1991). This is also influenced by behavioural or societal and cultural norms that create this resistance to change.

- **Justice, equity, distribution and diversity effects; winners vs losers** – solutions to system transformation should consider interspecies, intergenerational and intragenerational justice issues (Gupta and Koontz 2019). Carefully mapping the winners and losers and mitigating the unfair distribution of the costs on the most vulnerable and disadvantaged communities and groups – women, the elderly, children, and people with disabilities, among others – s vital. Any societal injustices associated with the transformation should be avoided.

- **Effects on Indigenous Peoples** – placing a special focus on the effects of the proposed solutions on Indigenous Peoples and other communities that maintain historical connections with place and nature, with particular attention to land tenure and land rights, is a crucial aspect to consider. The best strategy to avoid any adverse effects is to involve these groups in the decision-making processes from the outset.

- **Effects on animal welfare and the environment** – the rights of nature and nonhumans must be considered, and their agency should be included in the process. The solutions should be assessed through rigorous environmentalm impact assessments and those with comparatively less impact should be prioritized.

- **Economic and financial feasibility** – understanding the degree to which the economic advantages of implementation are greater than the economic costs. Financial risks of implementation should also be accounted for and distributed in a fair manner.

- **Technological evolution** – anticipate potential support or push factors and constraints or pull factors that the evolution of technology can provide to support solutions at the system level.

- **Scenarios solution space** – Chapter 10 provides a clear overview of plausible solutions for system transformations. The ensemble of solution pathways must fit the scenarios solution space and their storylines.

13.8.5 Step 5. Identify the specific combination of levers that incentivize actions that lead to self-sustaining momentum towards achieving transformative goals

The theory of levers and transformation is provided in 12.5. This step involves providing clear examples for levers that lead to actions that are transformative versus those that are not, in view of the given issue in a system. Identify the forces of radical change and those of stability and path dependence that need to be addressed by the levers, as well as their interplay. Levers are domains of societal influence that share a configuration of broad types of actors, actions, and analysis. The levers as identified in the Global Sustainable Development Report (United Nations 2023b) are Governance, Economy and finance, Individual and collective action, Science and technology, and Capacity building.

13.8.6 Step 6. Identify the options for short- and medium-term actions, and how they should be sequenced. Make decisions while also considering the socioeconomic, ethical, and environmental effects of the actions

Identify 10–15 actions that would result from the application of the levers to support a given solution pathway. These can be an intermediary set of actions that create an enabling environment for other actions to come into play. The sequencing and timing of each action is hence central to creating a viable solution pathway. Research highlights that understanding the interplay of various drivers and their timing is essential for effectively managing transitions in

Credit: tampatra/Envato

food systems (Moberg et al. 2021). Sequence and timing are key factors in promoting an efficient circular economy, ensuring that recovered materials are optimally processed and reused (Andriyani et al. 2024). In the co-production of knowledge framework, particularly in the context of environmental protection and recycling within energy systems, well-defined sequences and timing ensure that all stakeholders, including Indigenous communities, are involved from the outset. This involvement is crucial for building equitable relationships and addressing systemic inequities (Yua et al. 2022). These recommendations should be actionable and implementable, allowing for intentional movement towards transformation.

Action is defined by conscious decision-making to do something in the light of attaining the goal in each system, adhering to the given and previously selected solution. However, the actor is limited in their ability to choose from the options presented and accessible in each system. It is crucial to understand that social and collective actions also have powerful transformational effects and that a careful design of governance around system transformations is essential. Governmental interventions can have a profound influence on actions; government policies can create an enabling environment and context for transformation by determining the direction of transformation – phase in or phase out – through policy priorities and resource allocation. Each system chapter should explore the literature on the success of each action, including the diversity of instruments used to implement the actions. Financial systems and vested interests, as well as other lock-ins, should be considered in this literature review. Identifying failing actions and the reasons for their failures should also be part of the literature review. Try to select shorter-term or immediate actions to help ensure policymakers are accountable for delivering these actions within their term in office. Explore the impacts of these actions on technologies, governance and behavioural change. The effectiveness and efficiency of levers, policies, or actions, as well as their co-benefits or trade-offs, should also be researched and considered. Contextual requirements for each action should be detailed – and perhaps relate these requirements to the governance contexts Literature on ex-post and ex-ante analysis of actions should also be considered here.

The sequencing and timing of actions would also likely need to include adaptive measures, so that if a conflict, disaster, shock, or other barrier arose, there would be guidance for governments or other actors on the best solution pathway for adaptation.

In defining the sequencing of actions, consider the X-curve approach, that is, consider the phasing-out actions in parallel to the phasing-in actions. Actions should be envisioned for an intentional rising path that supports a sustainable system, and an intentional declining path that destabilizes an unsustainable system towards its exit.

13.8.7 Step 7. Identify and understand the responsible actors and their roles and interactions for realizing those actions

The politics of system transformations captures how different actors, and their groups can have diverse epistemological understanding of transformative solutions, and contest or align over the desired outcomes of transformations, including the measures to achieve those outcomes (Avelino and Wittmayer 2016; Kern and Rogge 2018). This means understanding whose vision, values, and discourse dominate when deciding the direction of future pathways and who wins or loses when those pathways are taken. Thus, system transformations are not only sociotechnological changes within each system but also involve shifts in power relations and the (dis)empowerment of actors (Avelino and Wittmayer 2016). In this sense, the politics of system transformations are closely linked to issues of legitimacy, justice, agency, and power among actors.

Stakeholders are all actors affected by a project, policy, study or decision, or who have an important influence on its outcome. Stakeholder analysis usually involves four stages: 1) identification of the system, sector or project under focus for example, a special theme where we need stakeholder engagement; 2) identification of the system boundaries and overall context, for example, location, geography, and time frame); 3) identification of stakeholders, for example, which individuals and groups); and 4) mapping, analysis, and prioritization of stakeholders.

The integration of diverse actors' perspectives begins with effective stakeholder identification and engagement, and it continues with the establishment of good governance around system transformations, including environmental education. This involves being attentive to the voices of non-conventional players and integrating the perspectives of scientists, youth movements, Indigenous Peoples as rights holders, local communities, and movements that tackle issues of poverty, race, gender, age, or ethnic disparities (Pascual et al. 2023). This stems from the recognition that system transformations are highly complex, uncertain and multidimensional processes. As such, they cannot be managed solely through a top-down approach by governments, and they require the involvement of a plurality of actors. The governance of transformations must seek to understand the needs and empowerment of stakeholders, and remain accountable to them, as well as to the governance processes, instruments, and outcomes.

Thus, in this step, the decision maker needs to:

- Identify the diversity of stakeholders or stakeholder groups.
- Politically map them according to the power to affect the transformation and be influenced by its results, that is, winners and losers.
- Identify the actors that might resist the change.
- Identify and assign the roles of actors for driving transformation and ensure the uptake by society as a whole.

The literature shows the many factors influencing the actions implemented at different levels: individual, community, civil society, governance, and private sector. These factors can reveal the drivers, obstacles, and catalytic conditions that influence the implementation of specific actions in the solution pathway, as well as whether these influences are positive or negative (IPCC 2022; Pascual et al. 2023). Recent literature highlights the need to develop multi-actor actions to achieve a beneficial synergy between the positive indicators and obtain positive social tipping dynamics (Petzold et al. 2023). The 7th step highlights the importance of considering all these indicators.

13.9 Monitoring and evaluation

A continuous evaluation process must be applied to achieve transformative change. Ex-ante and ex-

post evaluations, along with permanent monitoring procedures, using key indicators, including a gender perspective, would contribute to defining realistic goals, selecting feasible solution pathways, implementing actions by committed actors across the identified levers, and being capable of adapting to unforeseen events or unexpected situations.

Monitoring and evaluation help gauge whether the solution pathways under execution are performing in a way that aligns with the achievement of the proposed goals (Marwedel 2021). If not, the reasons for underperformance, for instance, due to unexpected scenarios, must be identified and understood before adjusting the actions (Luederitz et al. 2017). These processes need to be constant and dynamic (van den Berg, Magro and Salinas Mulder 2019) to stay on the correct path for a transformative change, but also to make effective use of scarce resources. Flexibility in actions and indicators is a prerequisite for a dynamic and continuous monitoring and evaluation process.

Thus, the continuous monitoring and evaluation process runs parallel to the implementation of the solution pathways and the GSL framework. It starts at the goal level, analysing if the goals are determined using participatory methods (FAO et al. 2023), and if measurable indicators of progress are defined (United Nations Framework Convention on Climate Change [UNFCCC] 2010; Turnheim and Nykvist 2019; UNEP 2019; OECD 2020; United Nations 2023a). Next, an ex-ante evaluation of the solution pathways under analysis needs to be performed, based on strong qualitative and quantitative data. Based on the top-down and bottom-up approaches used in the GEO-6 report and other evaluations experiences (van den Berg, Magro and Salinas Mulder 2019), the criteria to evaluate the alternative solution pathways are:

- effectiveness and goal achievement
- unintended effects
- setting of a baseline
- coherence and convergence and synergy
- co-benefits
- equity, and winners and losers
- enabling and constraining factors
- cost and cost-effectiveness
- time frames
- feasibility
- acceptability
- stakeholder involvement

The potential solution pathways need to be evaluated in the local context regarding their political feasibility, social and cultural acceptability, economic and financial feasibility, and distributional impacts on, for example, Indigenous Peoples as well as local communities (Turnheim and Nykvist 2019), among others, using credible data.

After Step 4, the selected solution pathway will be evaluated, regarding its capacity to address the relevant levers: Governance; Individual and collective action; Economy and finance; Science and technology, and Capacity building (United Nations 2023a).

For the sequence of actions that the selected solution pathway integrates, a proportionate monitoring and evaluation process needs to be designed and implemented. First, we need to conduct a quantitative-qualitative baseline analysis of the proposed indicators at the goal level, including gender disaggregation. Next, a monitoring procedure and intermediate evaluation of the actions for the solution pathway will be designed. The objective of the monitoring process is not only to measure progress, but also to learn from the experience, identifying changes or detours (van den Berg, Magro and Salinas Mulder 2019), to ensure that the transformative change is taking place. Additionally, the inclusion, role, and commitment of each of the relevant actors in the solution pathway should be evaluated (Fisher and Newig 2016). This continuous monitoring and evaluation process should be proportionate to the level of actions implemented. Finally, a systematization process should be designed to highlight the lessons learnt, the good practices implemented, and the improvements that can be made in future interventions. All these processes constitute the evaluation in the GSL framework. In the Appendix 13.1, a checklist of questions is included to help with the design and development of the evaluation process.

13.10 Concluding thoughts

This chapter proposes a significant advance in the field of systemic transformation by introducing a new methodology for developing solution pathways. The method's key strengths are innovation, integration, and adaptability.

The methodology is integrative in both scientific and social terms. Scientifically, it links abstract theories of transformation with concrete planning steps, thereby operationalizing complex concepts into actionable processes. Its 7-step approach offers a practical toolkit for overcoming deep-seated policy and systemic failures that continue to hinder progress on the SDGs. It is solution-centred and focuses on identifying system goals, solutions, levers, actors, and actions to be undertaken. The inventory of solutions includes modelling exercises, past initiatives, existing bottom-up solutions, Indigenous Knowledge and Local Knowledge. It reflects the six principles of transformation (12.4) and integrates monitoring and evaluation throughout the process, recognizing the need to constantly assess and adapt to stay on track for transformative change.

Socially, the model recognizes and integrates diverse knowledge systems, particularly Indigenous Knowledge and Local Knowledge, which are often marginalized in formal policy design. By placing these epistemologies on an equal footing with scientific and technical knowledge, the methodology fosters more legitimate, equitable and culturally grounded solutions. An inclusive engagement of all stakeholders must be sought at all phases of the effort to ensure broad-based ownership and political legitimacy. Absent such inclusion, the proposed solution pathways may simply maintain or reinforce existing systemic injustices. Inclusion is also important to gain legitimacy, achieving societal support and maintaining it over a long period (Beetham 1991).

The model is also adaptive, both internally and externally. Internally, it considers various interdependencies, including trade-offs, synergies and feedback loops. In so doing, it provides a more realistic account of the dynamics of systemic change while also facilitating the coherence of multiple policy interventions. Externally, the methodology can be adapted to address shocks and uncertainties. This feature, which facilitates response to emerging challenges, is vital in today's world where environmental, social and economic systems are susceptible to sudden disruptions. Overall, the methodology supports continuous monitoring, evaluation, and timely recalibrations that maximize the likelihood of transformative success.

Ultimately, the methodology's dominant feature is to be innovative. It advances the use of systems thinking at a time when the world must move beyond incrementalism and transform rapidly to address our global environmental crises in ways that are socially just, ecologically sound, and resilient to future shocks. Transforming systems means breaking away from business-as-usual, including in the realm of policy theory and methodology. The proposed 7-step methodology represents a significant step toward methodological innovation.

Appendix 13.1 Guidelines for the evaluation process in the GSL Framework

Steps	GSL Framework	Evaluation of Step or Procedure Check List	Literature
S1: Goals	Goals	• Are the goals defined using participatory methods? • Are the country/region priorities aligned with the selected goals? • Are there indicators and procedures to measure the progress and achievements of the goals for transformative change defined? • How are the goals connected to explicit representations of the system (configuration and boundaries) and structural sources of lock-in? • What needs to be removed, changed or maintained?	(FAO et al. 2023) (OECD 2020; UNFCCC 2010; Turnheim and Nykvist 2019)

S2: Source of solution:
• Prior attempts
• Local solutions
 	
S3: Set of selected solution pathways
 	
S4: Evaluation of the selected solution pathways in the local context.
• Political feasibility
• Social and cultural acceptability
• Economic and financial feasibility
• Equity, distribution and diversity impacts (winners vs losers)
Impacts on Indigenous Peoples as well as local communities.
	Solution pathways (SP)	Questions that may help S2–S4:
		
		• Are the solution pathways (SP) leading to transformative change?
		• Are there evidence-based evaluations of policies, actions or programmes that explain the results of the prior attempts?
		• Do models and scenarios provide feasible targets, considering time frames (i.e. 2030, 2050)
		• Are there literature or data that support the effectiveness or co-benefit of transformative actions, policies and programmes implemented for the solution pathway in a similar context? In different contexts?
		• Does the SP include intermediate results or targets to reach for getting the identified goal?
		• Are all potential actors involved identified?
		• Has the SP been validated considering multiple perspectives and approaches?
		• Does the political context facilitate implementation of the SP in the short and long term? Are there many actors capable of promoting the SP?
		• Are social and cultural actors interested in implementing the SP? Do these actors propose an active participation in the development of the SP?
		• Are financial resources available for funding the SP?
		• Are all actors informed about potential positive and negative effects of the SP selected (specifically, those who would be the losers in the SP)
		• Pre-defined criteria to evaluate the potential SP:
		
		  • Cost effectiveness and cost-benefit analysis for goal achievement; nintended effects; setting of a baseline;
		  • Coherence, convergence and synergy; co-benefits;
		  • Equity, winners and losers; enabling/ constraining factors;
		  • Cost; cost-effectiveness; time frames; technical feasibility; acceptability; stakeholder involvement
			(Turnheim and Nykvist 2019 p. 777-778)
			
			(Luederitz et al. 2017; van den Berg, Magro and Salinas Mulder 2019)

Steps	GSL Framework	Evaluation of Step or Procedure Check List	Literature
S5: Levers	Levers	Does the SP selected include notions of the following levers: • Governance • Economics and finance • Individual and collective action • Knowledge and innovation • Capabilities If the answer is no, the SP needs to be revised to make sure all the levers are included.	(Lamhauge, Lanzi, and Agrawala 2012)
S6: Sequence of actions	Levers	After the SP to be implemented is selected, the sequence of actions should be developed. Parallel to the definition of these sequences, a monitoring and evaluation process needs to be designed. 1. Ex-ante evaluation of the sequence of actions of the SP selected: • Is there an approved procedure to measure the defined indicators? • Is the SP economically feasible? Are the externalities and co-benefits of the SP included in the evaluation? 2. Monitoring: • Are there indicators (short and medium term) that can measure the progress of the proposed actions? • Is it possible to define a procedure to gather information for measuring the progress on the selected indicators? • Are there resources (funding, human resources) to periodically perform the monitoring actions? 3. Ex-post evaluation: • - Are there resources (e.g. human, financial, • technical) available to perform the ex-post evaluation?	(Lamhauge, Lanzi, and Agrawala 2012)
S7: Actors	Levers	• Are different types of actors involved in the design and implementation of the proposal government (at multilevel: local, regional, federal), private sector, consumers/producers, NGOs, international agencies, organized civil society? • Are there actors who support vs. oppose (e.g. funding, advocacy) the SP/actions proposed? • Is the plurality of actors hf? • Is a systematization process designed to highlight the lessons learned, the good practices implemented, and the improvements required for future interventions?	(UNFCCC 2010; Fisher and Newig 2016) (OECD 2020)

Note: The evaluation process is permanent and must consider the step in which it is located. For example, in Step 4, the solution pathway is evaluated in terms of how to achieve transformative change, while in Step 6, the evaluation focuses on determining whether the sequence of actions guarantees the achievement of the solution pathway.

Chapter summary

Credit: leungchopan/Envato

The current global economic and financial systems have inadvertently fostered economic activities that cause significant environmental and social harm (*well established*). In recent years, many efforts have focused on prioritizing more sustainable development principles. Nonetheless, environmental harm from economic activities is pervasive and insufficient action is being taken to address the adverse environmental effects. These trends exacerbate the global environmental crises. Scientific evidence confirms that the world is not on track to achieve the Sustainable Development Goals (SDGs). {14.2}

A well-informed, scientifically driven transformation of our economic and financial systems is necessary to meet the 2030 SDGs and targets (*well established*). Building upon growing interest in transforming our current economic and financial systems to balance the well-being of people and nature presents an opportunity to implement specific solution pathways (SP). Alternatives already exist for driving change and putting the economic and financial systems on a sustainable path. Public and private finance can play a crucial role in reorienting capital flows toward sustainable endeavours. {14.1}

Four solution pathways are identified to facilitate a timely, equitable, and steady transformation of the economic and financial systems (*established but incomplete*). These pathways emerge from a long-standing scientific debate on economic and financial policies and mechanisms to enable a sustainability transition. They explore the economic and financial system changes required to achieve the SDGs. To this end, a timely, just and equitable transformation is discussed within a framework that respects planetary boundaries and considers deep and complex interactions across multiple socioeconomic and environmental issues. Solution Pathway 1 concentrates on the actions required to price externalities adequately. Solution Pathway 2 relates to making sustainability mainstream in multilevel and multilateral governance, as well as in macroeconomic and fiscal policy considerations. Solution Pathway 3 concerns the financial sector, with an emphasis on tools and frameworks that can unlock private financial capital for environmental sustainability projects. Solution Pathway 4 considers the role and use of non-price instruments to engender pro-sustainable norms, attitudes and behaviours. The

numbering of these pathways in no way reflects either their relative importance, or sequencing. {14.2–14.5}

Some solution pathways are already implemented and need scaling up, while others have been tested and have not yet reached the desired outcomes, thus calling for a thorough consideration and update to achieve the desired socioeconomic and environmental goals (*well established*). Certain pathways and actions are based on promising experiences that need to be scaled up, for example, green finance. Others, such as pricing externalities, have had mixed successes, with some carbon markets not fully meeting their objectives. There is no ambiguity or contestability that pricing externalities is necessary for valuing externalities in environmental policy frameworks, hence its retention as a solution pathway. Yet the associated actions can be framed more concretely around the implementation barriers that still need to be overcome, particularly around public policy, awareness and institutional impediments. Ways of avoiding these barriers include redirecting subsidies, implementing higher taxes on polluting activities, offering tax incentives for non-polluting activities, and supporting investment in necessary future technologies. These solutions require data availability, improved socioeconomic and environmental models, big data analysis, machine learning, and artificial intelligence, among others. Transparency in framing and presenting these options is still crucial to attract political and public approval. {14.2}

Economic and policy targets and assessment must be framed within comprehensive principles (*well established*). The economic system needs to move beyond traditional measures of economic activity, such as gross domestic product, by setting up integrated socioeconomic and environmental accounting systems, such as building on existing approaches for natural capital accounting, to reflect a broader notion of progress for policy decision support (SP1– SP4). Lessons can be learned by understanding the links between the environment, sustainability, and well-being from many Indigenous Peoples as well as local communities across the globe. {14.2, 14.3.2, 14.3.3}

Environmentally harmful subsidies must be phased out or drastically reduced, depending on each country's circumstances (*well established*). Existing subsidies, such as for fossil fuels, agriculture and fisheries, which directly favour activities that have significant harmful effects on the environment, including on biodiversity, must be removed through a timely, planned process. Funds from the redirection of subsidies should be used to create innovative financing mechanisms, such as low-interest loans, more autonomous food systems, the use of renewable energy, less agrochemical-intensive agricultural production, nature restoration, and support for low-income local populations, among other initiatives. This approach will benefit the environment and improve the socioeconomic conditions of the most disadvantaged populations, for example, by strengthening Indigenous systems. (SP1) {14.3.1}

Externalities must be integrated into the pricing system that signals the efficient allocation of resources (*well established*). Environmental costs that are not captured in market prices when producing and consuming goods and services must be internalized in economic transactions to make market forces work in favour of sustainable pathways. For instance, the external costs of industrial air pollution from large industrial operators is equivalent to approximately 2 per cent of the European Union's gross domestic product (GDP), while at the global level, costs of fine-particle (PM2.5) air pollution reach 6.1 per cent of GDP, with estimates varying from 1.7 per cent in North America, to 9.3 per cent in East Asia and the Pacific, and 10.3 per cent in South Asia. Water pollution, the leading cause of waterborne and childhood diseases, but also of poisoning and cancer, represents 2.5 per cent of all deaths and 2.9 per cent of all lost days globally. Electricity systems could generate US$11.644 trillion in annual externalities, while transport could generate another US$13.018 trillion; when combined, this is equivalent to 28.7 per cent of global GDP.

From a climate change perspective, the social cost of carbon emissions is US$1,056 per ton of CO2, which is about 15 times the price of a ton of CO2 on the European Carbon Credit Market. Concerning food, at US$19.8 trillion, the current externalities are estimated to be more than double the current total global food consumption cost of US$9 trillion. This means that food is roughly a third cheaper than it would be if these externalities were included.

Internalizing externalities can be realized through both pricing and non-pricing approaches (*well established*). Efficiency in resource utilization can be improved through promoting circularity, restructuring fiscal systems, and fostering sustainable governance (SP1, SP2, SP4). For instance, a circular economy model, where waste generation and economic growth are decoupled by

adopting waste avoidance, sustainable business practices, and full waste management, could avert social costs of more than US$110 billion a year.

Revenues raised through pricing externalities can be used to promote system transformation and minimize distributional impacts (*well established*). Mechanisms such as carbon taxes and carbon markets, water charges, or fees for single use-plastics, as a few examples, contribute to promote the transition to more sustainable economic activities. If well managed fiscally, they can be used to offset distributional effects, funding green activities or reducing the tax burden on labour and capital elsewhere. (SP1)

The estimation of external costs and benefits and their pricing are not trivial processes (*well established*). Different pricing tools may be better suited than others. Appropriateness depends on the policy aim, the nature and scale of the externalities, data and expertise availability, the distribution of the degradation sources, and inequality repercussions. Local institutional capacities and implementation costs must be considered when pricing externalities. (SP1)

Participation and communication strategies in different forms and from diverse sources cannot be neglected (*well established*). Proposed pricing policies and instruments must be well communicated, with a clear and coherent presentation of the total expected benefits and costs, in both the short and long run. More importantly, it should be clear to whom benefits will accrue and how distributive and competitive effects will be addressed, to engage the public and private sectors and, consequently, policymakers and legislators, in support of these policies.

Non-pricing approaches are a necessary complement to price-based instruments for shaping pro-environmental behaviours (*well established*). While price is a powerful force in coordinating economic activity, decision makers also base their actions on other factors – such as preferences, habits, norms and cultures and corrective pricing may not be feasible or fully effective in all cases. Non-pricing tools are therefore necessary, which may include regulatory approaches, soft approaches such as eco-labelling, research and development, and self-regulation or governance and should take into consideration people's ethics and moral values towards ecosystems, which is particularly relevant for Indigenous Peoples as well as local communities (SP4). The suitability and performance of each approach need to be carefully weighed when choosing among them. {14.3.4}

The economic transformation must integrate a nature-positive economy approach, recognizing that long-term prosperity depends on ecosystem health (*established but incomplete*). Policies should prioritize investments in biodiversity, ecosystem restoration, and nature-based solutions to foster a regenerative, resilient, and inclusive economic future. Initiatives such as the Kunming-Montreal Global Biodiversity Framework and the Taskforce on Nature-related Financial Disclosures offer vital guidance for embedding biodiversity considerations into economic governance.

Sustainable finance is an essential enabler and cultivating tool for sustainable economic activity (*well established*). To foster green finance, there is a need to reorient public funds and steer the private sector to place value on the environment, including biodiversity and avoidance of environmental-related risks (SP2, SP3). The estimated cost of delivering net zero GHG emissions by 2050 is US$ 150- 200 trillion (approximately 8 trillion per year). Fragmented sustainable finance frameworks have emerged, with incomplete coverage or implementation within countries and incoherent connections across countries. Reducing fragmentation and enhancing compatibility is required through, for example, the adoption of a common taxonomy to achieve interoperability around the world. Coordinated action across different levels and spaces is required to make the most of the globally mobilized capital that supports the sustainability transition (SP1, SP2, SP3). {14.5.1, 14.5.2}

Making sustainability central to governance, global coordinated action, risk evaluation and management (*well established*). Governance should evolve at local, regional, transnational, and global levels to facilitate coordinated action for the sustainability transition at various levels (SP2). Core actors, especially those that can financially propel the sustainability transition need to be identified, interconnected and jointly mobilized to serve the transition in a timely, just and equitable manner (SP2, SP3). Recognition and strengthening of local governance structures, and Indigenous Peoples and local communities, is necessary to achieve social and environmental sustainability. Revised perceptions of risk are needed, taking a holistic approach to quantifying environmental and sustainability-linked risks connected with business and investment decisions (SP2, SP3).

Accounting for all financially material effects, risks, and opportunities will ensure the confident inclusion of sustainability in financial decision-making. This will also enhance the overall resilience of the financial sector to a more comprehensive array of physical and transitional risks and shocks, by centralizing sustainability within risk management frameworks (SP3).

The undue pressure for short-term performance in financial and economic decision-making must be reduced for finance to prioritize environmental sustainability effectively (*established but incomplete*). Investments in environmental objectives require a long-term orientation that contrasts with the prevailing short-term high-return practices (SP2, SP3). This requires a balanced and transparent approach that utilizes the most effective levers across the system, including capital providers, capital seekers, policymakers and regulators. {14.4.4, 14.5.4}

Actions, such as overall capacity expansion and preparedness steps, are shared priorities for all solution pathways (*established but incomplete*). Achieving the goals of the solution pathways will involve actions common to all, for example, capacity expansion in terms of both the quantity and quality of relevant human capital to deliver the pathways. Preparatory steps will have similar attributes for each pathway, including reviews of existing mechanisms, laws, regulations and policies, as well as engagement with all members of society on the ways in which they are both necessary and exciting opportunities to embrace transition in the economic and financial systems. {14.4}

System transformation will only be achieved through combining solution pathways to achieve the desired socioeconomic and environmental goals (*well established*). The co-development of other complementary pathways strengthens individual pathways. Focusing solely on an individual solution pathway risks adverse side effects on the other three pathways or forgoing potential synergies, thereby missing multiple co-benefits. A holistic perspective based on the joint implementation of these pathways increases efficacy, prevents lock-ins and mobilizes opportunities to accelerate and leverage the transformation towards a sustainable economic system. Adaptive management and implementation of solution pathways can address evolving country conditions, by switching between, or rebalancing focus among the different solution pathways. To this end, various synergies among the solution pathways are not only recognized but should be exploited. For instance, revenues from the internalization of externalities (SP1) can be used to support green financing instruments (SP3), tools such as environmental, social, and governance ratings, and also addressing growing consumer demand for greener products (SP4), all facilitated through well-structured macro-governance systems (SP2). {14.4}

Important synergies exist between the economic and financial systems, as well as with other connected systems for food, energy, circularity and environment (*established but incomplete*). Broadening the scope of economic and financial systems is essential to ensuring that they are based on valuation frameworks that account for a wider and more inclusive range of societal and ecological values. These values are fundamental to Indigenous Peoples as well as local communities and their significant contributions to managing natural systems and ecosystem services in the context of circularity principles and restoring the natural cycle. Promoting such synergies and values will enable a more balanced allocation and use of resources to maintain ecosystems, people's well-being, and societal resilience. {14.4}

14.1 Introduction

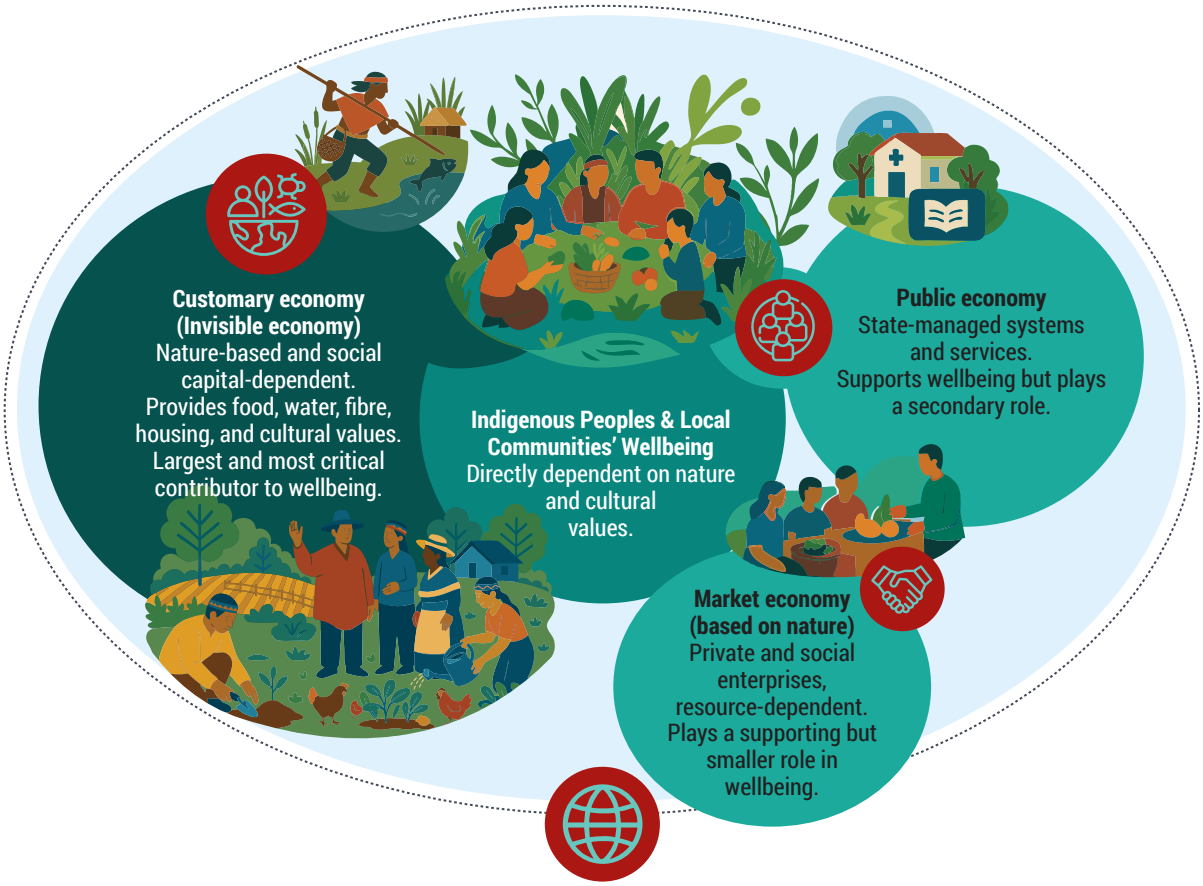
Economic and financial systems exist to help organize markets for goods and services and to facilitate the efficient use and allocation of typically finite, and often non-renewable, resources. Through their roles in pricing and facilitating the exchange of resources, these systems shape the boundaries of economic transition and development pathways. Yet the current economic paradigm, with economic activity being exploitative and fossil-fuel intensive, is contributing pollution pressure and accelerating the unsustainable use of air, land, and water, among other natural resources (World Bank 2023), and creating systematic risks for investors, businesses, the financial system, governments and society. The benefits and consequences of the unsustainable use of these systems are unequally shared among human societies across global, regional and local scales, with disproportionate effects on many Indigenous Peoples, as well as local communities. There is a need to recalibrate the economic paradigm to be less dependent on extractive resources and more integrative of environmental limitations and social development needs across sectors and activities. This is a precondition for the transformations that need to be achieved in efficient circular systems of resource use, and in the energy, food and environment systems.

The key features of a well-functioning modern economic system include people, as residents, decision makers, entrepreneurs and the providers of labour, as well as physical resources, including land and natural resources. There are also several necessary institutions, including governments, legal and regulatory systems, and financial markets, to steer capital flows efficiently. These institutions serve an important purpose in providing critical economic infrastructures of common societal value, but they are either undervalued by individuals, as in the case of education or the environment, and cannot realistically

Credit: StructuredVision/Envato

be provided by private parties, for example, transport and communication networks.

Economic systems can be broadly characterized as either a market economy or a planned economy. In a pure market economy, the choice is made to rely on unfettered market forces, that is, the actions of sellers and buyers of goods and resources to determine how resources are allocated. In contrast, a pure planned economy approach would see resource-allocation decisions determined centrally by governments. There are compelling reasons for placing trust in market forces, yet in real-world settings there are many instances where markets, left to their own devices, fail to allocate resources as desired, for example, as a result of negative externalities and information asymmetry, among others. In such conditions, government intervention can be pivotal to achieving well-functioning markets, particularly where private and social costs or benefits of resource use diverge, as has been the case with environmental resources. In practice, most economies operate somewhere between the two extremes of market and planned configurations, balancing the efficient allocation of resources and equity in the distribution of wealth and welfare, and tailoring them to local conditions.



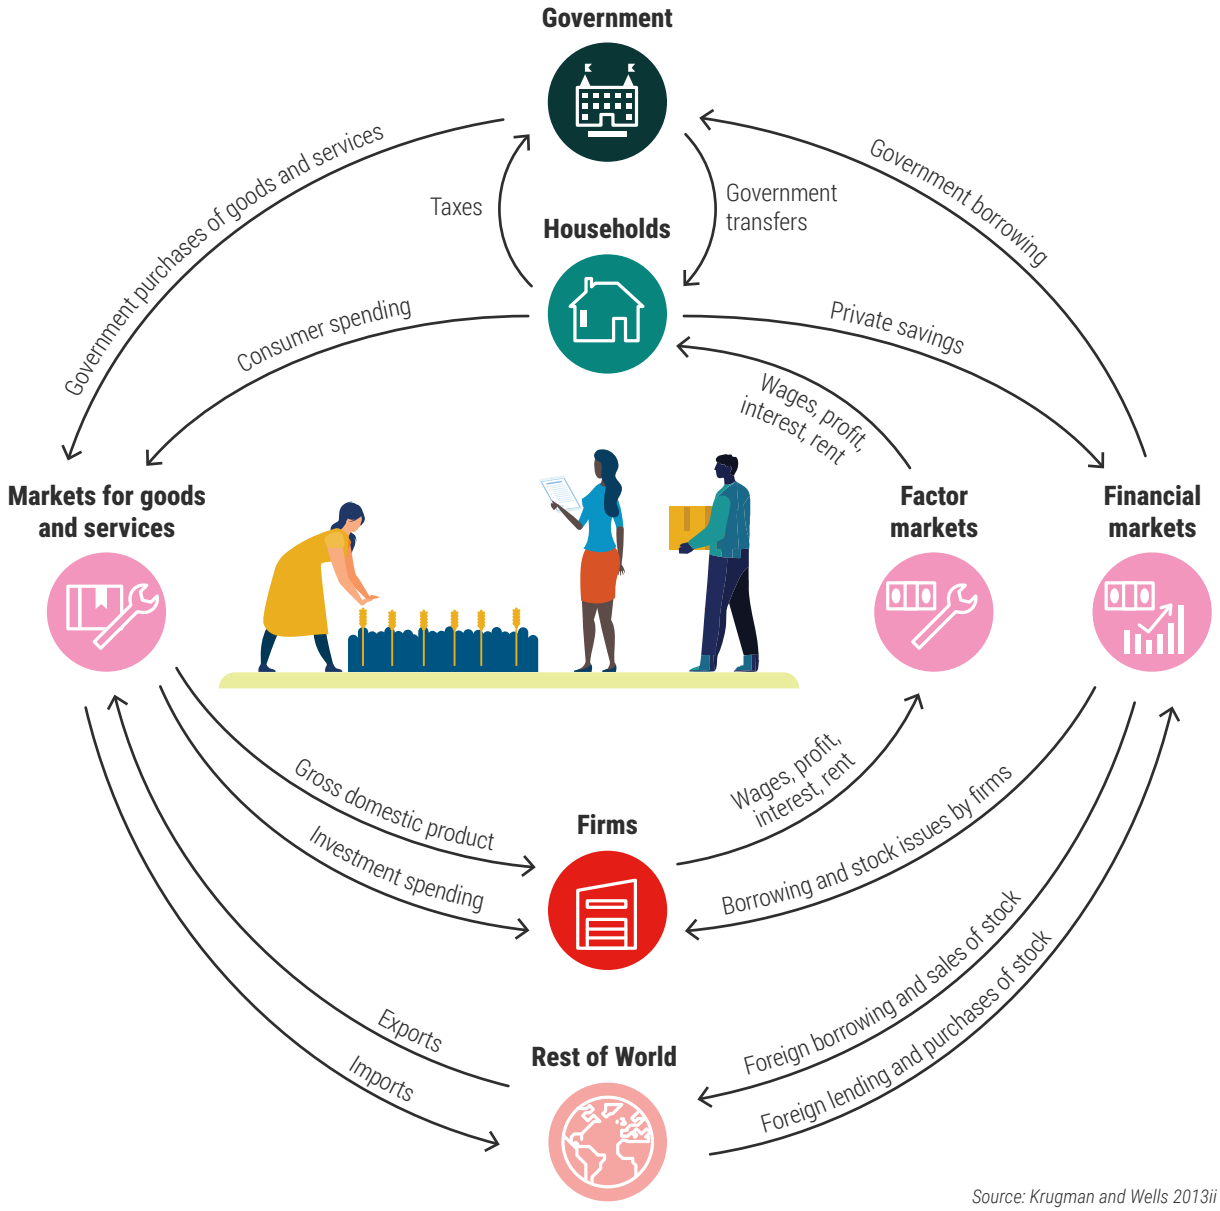
Current economic and financial systems are built on a set of values and valuation methods that are applicable to mainstream society and consider only the instrumental and monetary values of nature (Dasgupta 2021; Intergovernmental Platform for Biodiversity and Ecosystem Services [IPBES] 2022). There is a growing awareness that our modern economic systems depend heavily on nature (Costanza et al. 1997; Costanza et al. 2014), with around 50 per cent of global gross domestic product (GDP) originating from sectors moderately or heavily dependent on nature (United Nations Environment Programme [UNEP] 2022; PricewaterhouseCoopers [PwC] 2023). In supporting the growth of these systems, our activities have transgressed six out of nine planetary boundaries (Richardson et al 2023), with an estimated loss of US$7 trillion in externalities each year through the loss of pollinators and other biodiversity, land degradation, greenhouse gas emissions and pollution, among others. Moreover, global, regional and national sustainability agendas take little account of the fact that natural resources are finite and non-substitutable (UNEP 2024). Indigenous Peoples and many local communities often adhere to value systems that are embedded in nature. Their resource utilization from natural systems applies integrated and relatedness perspectives, such as Mother Earth or Mother Nature (Sangha and Russell-Smith 2017; IK & LK Dialogues 2025). Their worldviews, which encompass the intrinsic and relational values of nature, and focus on social-environmental balance, local economies, and environmental justice, contrast with the mainstream economic thinking that has become reliant on extractivism, extended value chains and perpetual growth (Sangha 2020; IK & LK Dialogues 2025).

Indigenous Peoples as well as local communities comprise about 2.5 billion people, with 476 million Indigenous People from 50 countries (International Labour Organization 2020; Rights and Resources Initiative 2023) and they depend closely on nature and its services to support their well-being and livelihoods. However, their economies are largely invisible to the modern economy (**Figure 14.1**). Traditional ecological knowledge, cultural practices and values are key to sustaining and regenerating biodiversity and nature's services (IK & LK Chapeau D). Deliberate integration of the capabilities, skills, knowledge and related cultural practices used by Indigenous Peoples, as well as some local communities, into mainstream economic systems, governance and policy design can help the transition towards sustainability. As a co-benefit, this integration will pay dividends in the future management of nature's resources at a global scale (Sangha and Russell-Smith 2017; Sangha et al. 2021; Balasubramanian and Sangha 2021).

At a broader level and to maximize effectiveness, the required range of policies and practices needed to implement the solution pathways and support transformative change in the economic and financial systems must be inclusive. These policies and practices need to place greater emphasis and attention on integrating the role of Indigenous People, communities and local knowledge. Similarly, integrating gender perspectives is also essential for achieving inclusive and equitable development. Economic transformation must account for gender disparities to ensure equitable benefits for both men and women from economic growth and sustainability initiatives. This includes promoting women's participation in green jobs and ensuring that economic policies do not disproportionately disadvantage women.

The financial system includes macroeconomic finance and central-banking systems together with traditional banking systems, insurance providers and pension

Figure 14.1: An outline of the Indigenous Economy



Note: This figure highlights Indigenous Peoples and local communities' direct dependence on nature. They operate in a hybrid economy comprising: 1. Customary economy – mostly based on nature and social capital, comprising the largest part; 2. Public economy – managed by the State governments; 3. Market economy – managed and run by the private sector, including local and/or social and private enterprises. Among these, the customary economy is the largest and plays a critical and direct role in people's well-being, followed by the public and private sectors (the thickness of the arrows corresponds to importance). The outer circle denotes the broader State/Regional level socioeconomic, cultural and political systems that shape and impact Indigenous economies.

funds, equity and commodity markets among others. The financial system operates as an enabler of the economic activity through its crucial role in facilitating the allocation of resources by enabling economic transactions that are fairly and consistently priced with diligent consideration of the risks attached to investments (**Figure 14.2**). In so doing, they increase trust and enable capital allocation to occur with greater confidence while offering fair compensation. The financial system promotes stability and confidence within an economy.

The current economic and financial systems have underdelivered on the SDGs. There are several reasons for this, including:

- Societal and environmental costs and benefits in producing and consuming goods are not fully captured in market prices as a result of market, government, and/or incompatible behaviours;
- Incompatibility between incentives for directing capital flows and SDGs;
- Limited monitoring and accountability for environmental externalities and risk perception biasing measures;
- Short-termism and increasing levels of speculation in financial markets;
- Markets heavily discounting future cash flows, demagnifying the effects on future generations;
- Normative and cultural institutions fail to instil green awareness in daily, corporate, and national decision making; and
- Failure to apply ethics principles to market and financial systems.

Figure 14.2: Finance and the economy - an extended circular flow diagram of an economy

Source: Krugman and Wells 2013ii

The incumbent economic and financial systems display a low awareness of, and in many countries a high level of inaction for, normalizing environmental sustainability. Current systems must also be overhauled to match the ideals and values propagated by sustainable development. Procrastination only serves to exacerbate the global environmental crises, with major and enduring adverse effects on society, including human well-being and capabilities, food systems and food patterns. including human well-being and capabilities, food systems and food patterns.

Transformation in the structure and use of our economic and financial systems is urgently needed on a global scale. An expanded economic toolkit, built upon comprehensive measures of economic progress, must prioritize a more balanced definition of prosperity. The traditional leading economic indicator, GDP, in its broadest sense reflects how much monetary income or output a country generates within its fixed borders and is usually measured across a given year or quarter (World Bank 2021). However, GDP accounting does not capture resource use and degradation, nor does it account for the externalities associated with economic actions, that is, it does not reflect all the social benefits and costs of economic activity (Costanza et al. 2014). To solve such problems, the UN developed the System of

Environmental-Economic Accounting in 2012 and the System of Environmental-Economic Accounting: Ecosystem Accounting in 2021. A significant number of countries have implemented these systems through systematic accounts or registries that organize information on the state and dynamics of ecosystems, as well as their interaction with the economy. However, not all these countries have fully implemented all environmental accounts or registries. To this end, taking into account the literature (Our Common Agenda 2023; Stiglitz et al. 2018), this approach proposes supplementing GDP with a panel of indicators to include metrics that assess ecosystem health, biodiversity integrity, and natural capital value, recognizing that both systems can complement each other.

Natural systems contribute to human well-being, not only as inputs to the production of consumer goods, but also through combinations of use and non-use values, including flood protection provided by mangroves to coastal cities, the sequestration of CO2 by forests, and the maintenance of biodiversity. However, since they are often not priced in nor their contributions accounted for in modern economic and financial systems, these benefits can be difficult to realize (Bastien-Olvera and Moore 2022).

There is increasing consensus around the need to replace the goal of unlimited increase of economic growth as it is not achievable, given the planet's environmental limits (Kallis et al. 2025). As a result, global sustainable development is being constrained as rapid economic growth leads to resource scarcity and environmental degradation (Lv et al. 2022). In addition, the consequences of our unsustainable systems are unequally shared across different countries and within national populations, with the worst consequences for vulnerable societies in developing countries (International Federation of Red Cross [IFRC] 2018; FAO, UNDP, and UNEP, 2021; Damania et al. 2023).

The ultimate goal of economic development is to enable fair living standards for present and future generations on a shared planet with other living species. Realizing this goal requires continuing to use land and natural resources, labour, and capital to produce goods, while maximizing the efficiency of resource utilization, minimizing the emissions of pollutants and greenhouse gases, and balancing other social objectives such as equity. A paradigm shift is needed for the transition towards more resilient, healthier and inclusive economies (UNEP and International Resource Panel [IRP] 2024). A more sustainable and equitable path forward requires the following:

- Redesign of our economic system and development paradigm, placing environmental costs and benefits, and ethical principles of justice and equity at its core;
- Reorientation of capital flows towards environmental sustainability; and,
- Reshaping normative and cultural values to realize a thorough green transformation.

Achieving transformative change requires understanding key actors in the economic system, and their roles in decision-making regarding resource allocation, production organization, and goods and services distribution. Market failures cannot be solved purely with market-based solutions; governments, markets, and society all play important roles. There is an urgent need to rebalance the playing field with favourable institutional conditions that account for economic, environmental, and social effects on people and the planet, while fostering sustainable production and consumption patterns. Further, changes must recognize and address information asymmetries that lead to different decisions and opportunities among economic agents. Acknowledging that "…contributing to and achieving the SDGs offer a compelling growth strategy for businesses and for the world economy as a whole" (Business and Sustainable Development Commission 2017) renders sustainability-oriented transformation attractive. As a way forward, considerations should include:

- In current economic systems, natural resources are massively undervalued, ecosystem services are not paid for or are underpaid, and the rights of using common resources are not clearly defined, making the formation of price signals impossible. Barriers to transformation need addressing,and favourable institutions should be created or strengthened to facilitate the formation of optimal prices for, or to recognize the value of natural resources and ecosystem services.

- Beyond using pricing, a green mentality is also needed to drive transformation, requiring fundamental change in our normative and cultural value systems. Both coercive and incentive approaches, such as regulation and exhortation, are needed to facilitate green behaviours and to revolutionize the current value system regarding our relationship with nature.

- A more holistic and less transactional approach from the financial system requires a focus on making all business and investment decisions more sustainable, enhancing advisory services, and accounting for all detrimental and beneficial effects on people and environment. This approach will be aided by utilizing the most effective levers across the system, including capital providers, capital seekers, policymakers and regulators.

Moving away from the linear economic model and transitioning to a regenerative growth model that gives back to the planet more than it takes is essential to keep resource consumption within planetary boundaries (Raworth 2017). The current linear pattern continually increases its demands on scarce natural resources. Committing to circular economy principles ensures that sustainable products, services and business models become the norm, and catalyses the transformation of consumption patterns.

Transformation requires multiple actions, utilizing the structure and workings of economic systems based on their first principles. Many actors will need to cooperate in driving forward one or more actions in tandem to ensure transformative change in economic and financial systems. These actions are described within four solution pathways aimed at recalibrating central attributes of the supporting systems (**Figure 14.3**).

- SP1: the revised use of pricing mechanisms to internalize the externality

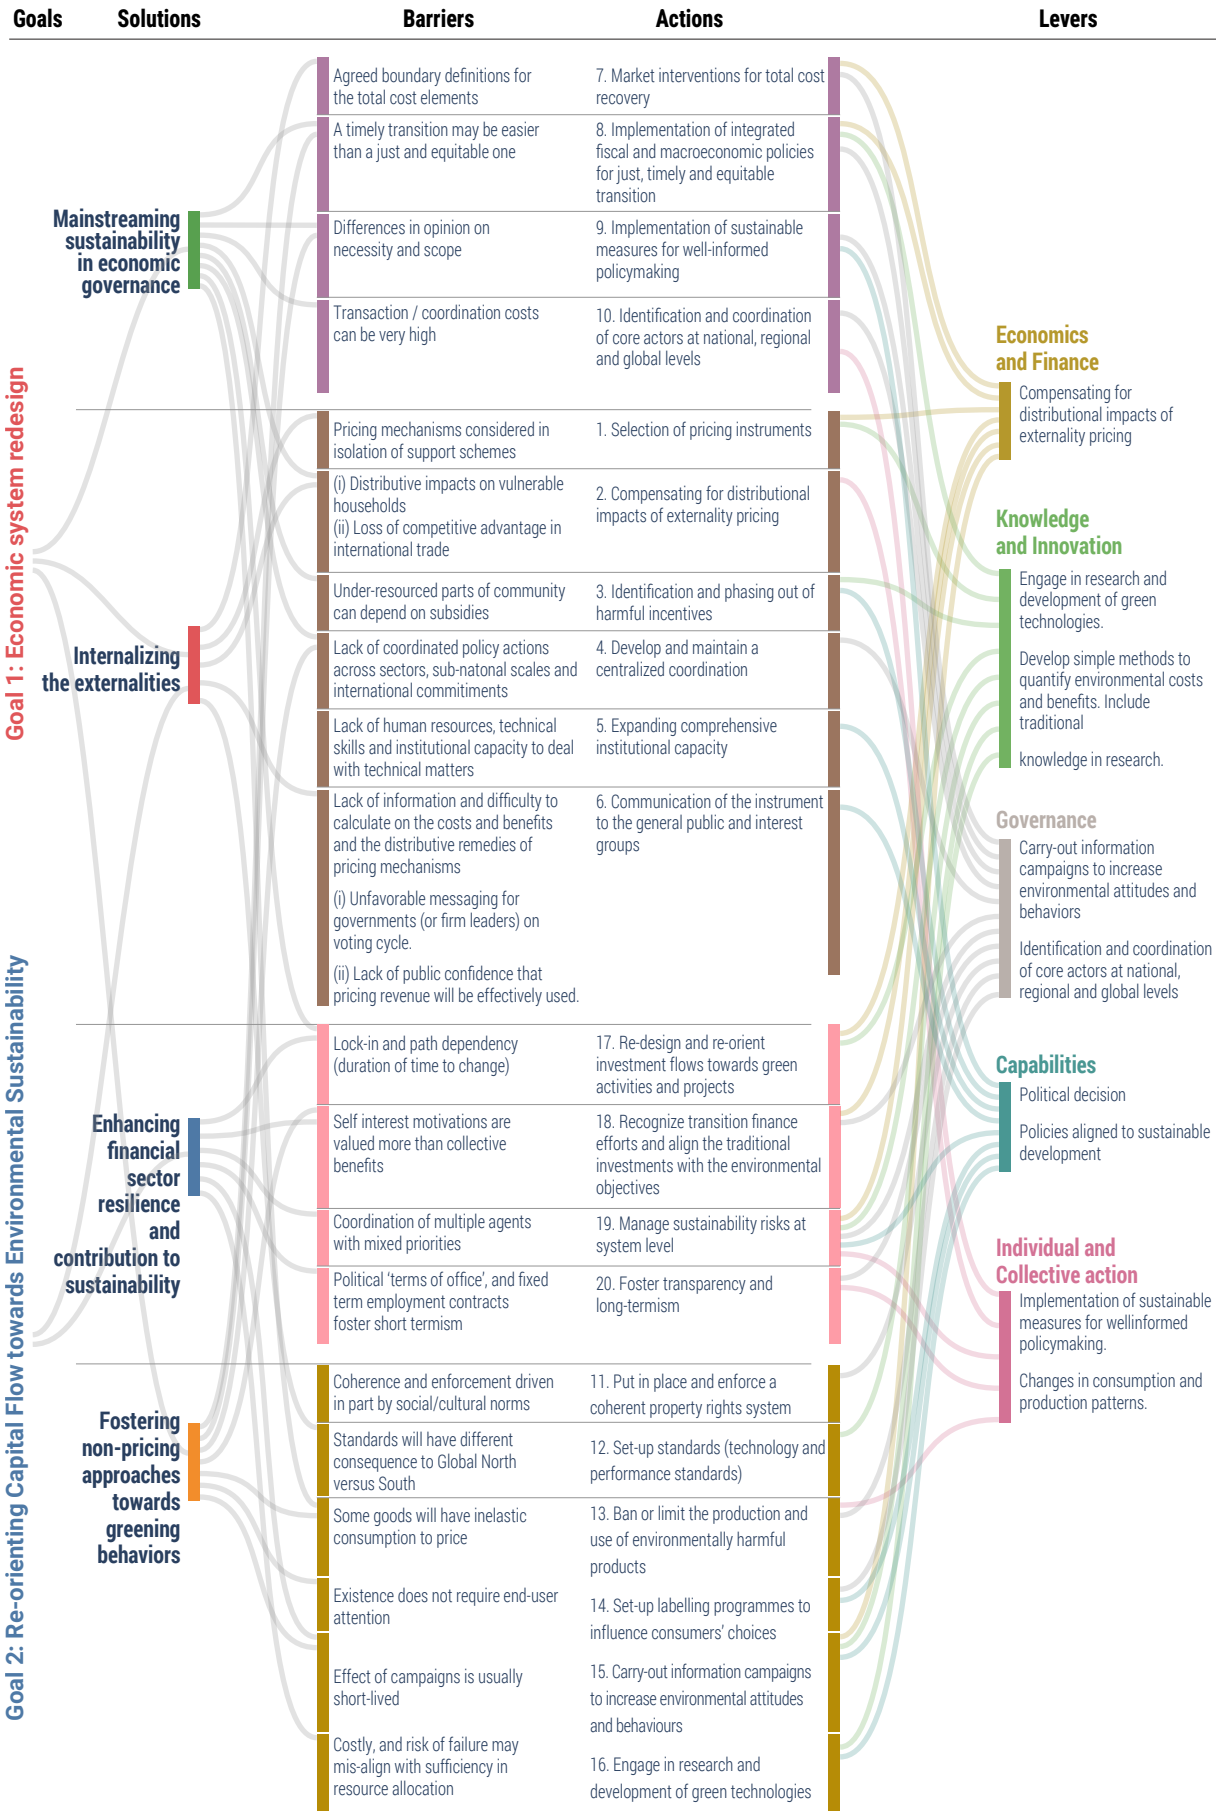
- SP2: reconstituting macro-level governance architectures

- SP3: accelerating and expanding the deployment of green and climate finance mechanisms for steering private sector capital

- SP4: making more extensive use of non-pricing mechanisms to guide our consumption choices and broader economic actions.

These solution pathways have been selected on the basis of their policy relevance and actionable system features. Another reason is their capacity to change the current situation due to their incremental and innovative conception of how economic activity can be organized, such as promoting circularity. Finally, they represent necessary solutions such as pollution taxes that, despite mixed successes, remain an essential component of future policy and have irrefutable scope for scaling up and duplication to different contexts.

These pathways can be conveyed cumulatively through the lens of two overarching goals for achieving transformative change in the economic and financial systems, as follows.



14.1.1 Goal 1: Economic system redesign

The economic system transformation required to achieve the SDGs, providing a just and equitable future for all on a stable and resilient planet, involves deep and complex interactions across multiple socioeconomic and environmental issues. Focusing on any individual solution pathway entails the risk of missing out on benefits unique to a given pathway or forgoing potential synergies. The four solution pathways proposed here are integrated and complementary, with multiple parallels and co-benefits available through their joint implementation. For instance, internalizing externalities (SP1) through taxes, charges and tradable permits can generate a flow of funds to support green financing/projects (SP3), favouring more sustainable production that meets growing consumer demand for greener products (SP4), supported by economic governance with coordinated policies at national and international levels (SP2).

14.1.2 Goal 2: Reorienting capital flows towards environmental sustainability

Steering capital flows towards addressing the global environmental crises is a key enabler of the transformation towards sustainable economic systems. Easing access to capital in the right place and at the right time will foster innovation, scale up low-carbon technologies, and accelerate the transition to a greener global economy. To this end, there are

Figure 14.3: Goals, solutions, barriers and levers diagram to show combination of solutions and levers to achieve goals for the economic and financial systems

important synergies among the solution pathways presented here and other systems. For example, a measure such as policy support to research and development of low-carbon technologies may tackle the internalization of externalities (SP1), green financing (SP3) and the needed behaviour changes towards higher sustainability (SP4).

14.2 Solution Pathways to achieve transformative change

Economic activity and sustainable development are not mutually exclusive and must be achieved in parallel and along the same trajectory, not in competing or opposing directions. A range of options is available for driving transformative change and placing the economic system on a more sustainable path, integrating renewed public investment strategies with increased efforts to direct private capital, while avoiding lock-in to unsustainable practices. These include both direct controls, such as pollution limits and quotas, and market-based instruments, including charges, taxes, fees, the redirection of harmful subsidies, tradable emissions permits, and payments for environmental services. Other examples are given in the Organisation for Economic Co-operation and Development (OECD) Policy Instruments for the Environment Database (OECD 2023a).

Four solution pathways are proposed to address existing market failures and re-optimize investment incentives for the private sector. Because many natural assets are public goods, the undervaluation of inherent environmental benefits in investments, and information asymmetries, the market alone cannot deliver optimum environmental benefits. Public sector intervention is warranted to mitigate such market failures, particularly for projects that offer positive environmental benefits. The delivery of environmental benefits most often hinges on public sector intervention, whether through regulation, incentives, taxation or even provision of goods and services. Without these, private sector stakeholders are unlikely to engage in reducing pollution, their environmental footprint, or soil and water conservation.

In addition to market failures, both private and public sector promoters face numerous barriers that hinder the design and implementation of investments. There are common financial market barriers to redirecting capital towards sustainable investment consistent with those that limit the development of and access to financial markets more broadly (Intergovernmental Panel on Climate Change [IPCC] 2023):

- There are varying levels of country indebtedness, economic vulnerability, regulatory uncertainty and fragmentation, perverse incentives and subsidies, as well as differences in administrative procedures. Coupled with this is a lack of international assistance and coordination, resulting in slow uptake for green de-risking facilities. Particularly among low-income countries with low credit ratings, sometimes below investment grade and unattractive risk-return profiles, underpinned by missing or weak regulatory environments or misaligned ambitions (Matthews and Karousakis 2022).

- Market infrastructures are sometimes improperly implemented, inhibiting a well-functioning banking system, leading to inefficient capital markets such as regional mismatch between available capital and investment needs, higher cost for sustainability products, and prevent sustainability-related impacts from being accurately reflected in traditional financial statements.

- Market size and structure affect the financial viability of investments. Different structures and standards between countries can make investments more difficult.

- A lack of budgetary resources to design and implement investments is a common problem for public sector investment promoters, as are weak planning and preparation capacity, especially for complex investments.

- Limited choice and access to affordable finance are barriers frequently encountered in the private sector, particularly among small to medium-sized enterprises (SMEs). Many firms in low-income countries and SMEs struggle to find sustainable finance instruments that apply to their primary industries, and SMEs often lack the expertise and sufficient capital to access green loans or green bonds market.

- Limited institutional capacities make it challenging to ensure safeguards or provide adequate assessment of climate-related and pollution or biodiversity-related impacts, risks and opportunities.

- There is low investment due to a risky environment with increasing severity, unpredictability and frequency of risk events. Related risks include political risks such as conflicts, climate risks like drought, geo-physical risks such as earthquakes, and pollution risks, as well as epidemics and disease outbreaks.

The proposed solution pathways not only need to address multiple market failures, but also to overcome or circumvent the need to face the various barriers described above. **Figure14.4** presents an overview of how these are linked with supporting actions that are required to be taken.

Solution pathways must also be nature-positive, ensuring that economic and financial systems actively contribute to ecosystem regeneration. Leveraging biodiversity-inclusive financial instruments and nature-based solutions (NbS) will create economic value while preserving planetary health. Governments, businesses, and financial institutions must work together to align investments with nature-positive objectives, fostering long-term resilience and prosperity.

Growing awareness of society's dependence on natural resources has elevated the importance of locally led adaptation to address climate risks, especially those faced by Indigenous Peoples as well as local communities. (Coger et al. 2022) highlight examples of how the local knowledge of communities and institutions can provide more coherent, flexible and cost-effective adaptation solutions. Indigenous Peoples as well as local communities, have been operating their nature-based economies for millennia and hold enormous potential to contribute towards developing and redesigning innovative, solution-focused approaches to modern economic and financial systems.

Indigenous and local communities' economies hold enormous potential to drive solutions-focused approaches that both grow Indigenous economies and increase well-being. The Periyar Tiger Reserve in the Western Ghats of India is a notable example, spanning an area of 777 km² in the state of Kerala. Credit: wirestock/Envato. The Indigenous Adivasi communities, comprising over 225,000 people, have been living in harmony with tigers and other wildlife for millennia, contributing to the state conservation economy while preserving their own. Due to its high conservation value, the area was declared a reserve in 1978 under India's Wildlife Protection Act (1972), which affected the Adivasi economies and rights. However, in 1996, India's State Forest Department, together with the World Bank, implemented an eco-development project in the tiger reserve. The project supported Adivasi communities in developing alternative livelihood-related economic opportunities and reduced their economic dependence on natural resources within the reserve. Village-level eco-development committees were established with Adivasi communities given key roles in informing forest management and advancing their aspirations, in collaboration with the Forest Department (Bhardwaj 2023).

Supported by the eco-development committees and project initiatives, Adivasi people from Periyar Tiger Reserve and nearby conservation areas grew local economies through cultivating local crops, ecotourism, employment as forest watchers, forest guides, and revival and recognition of tribal culture. The government allocated land for cropping to Adivasi families living within the reserve, who cultivated a variety of crops organically without clearing the land. Organically grown pepper and cardamom are of a higher quality that fetches better prices in the market. This initiative generated income and sustained more than 200,000 person-days of employment, while also boosting the state's tourism economy, conservatively estimated at roughly US$300,000 per annum, with over 600,000 visitors per year (information obtained from the Forest Department). Gender equality was also supported through the active participation of women in crop cultivation and management, as well as the establishment of a specially designated eco-development committee, Vasantha Sena, where more than 60 Adivasi women volunteer to protect the local sandalwood forest, previously a target for illegal harvesting (Bhardwaj 2023).

Another relevant example includes Lattu Lifespring, a community-based organization in Isiolo County in northern Kenya with support from the PAWANKA Fund (2021). Through community dialogues, Elders

Figure 14.4: Solution Pathways for Transforming Economic and Financial Systems

Making prices reflect true costs (Internalizing the Externalities)

Objective: Incorporate environmental and social costs into pricing systems to incentivize sustainable production and consumption while addressing market failures.

Strengthen government capacity to design, enforce, and monitor pricing policies.

Apply taxes, charges, or cap-and-trade systems to correct the price of goods and services that generate pollution, biodiversity loss and land degradation.

Promote Payments for Environmental Services (PES) to support carbon sequestration, watershed protection, and biodiversity conservation — including Indigenous and local conservation systems that sustain these ecosystem services.

Phase out environmentally harmful subsidies and redirect funds to sustainable alternatives.

Clearly communicate the benefits of these pricing policies to build public and industry support.

Mainstreaming sustainability in economic policies

Objective: Make sustainability a core part of national and global economic governance, ensuring inclusive and coordinated transitions.

Align government budgets and economic policies with sustainability goals.

Ensure businesses and industries cover the full costs of environmental damage through policy interventions.

Ensure economic policies consider both environmental and social fairness.

Improve coordination between local, national, and international policymakers.

Ensure inclusive economic governance by actively engaging Indigenous Peoples and Local Communities in decision-making processes, recognizing their governance systems and knowledge.

Strengthening the financial sector's role and resilience in sustainability

Objective: Align financial systems with sustainability goals by directing investments toward environmentally responsible projects and reducing financial risks linked to climate change.

Increase transparency in financial markets and promote long-term decision-making over short-term profits.

Improve international cooperation to set common financial rules and sustainability standards.

Support industries transitioning to sustainable practices while ensuring traditional investments align with climate goals.

Shift investments toward green technologies, clean energy, and low-carbon solutions.

Encouraging sustainable choices beyond pricing

Objective: Promote environmentally friendly behaviors through laws, education, and technology, to complement pricing mechanisms.

Establish clear property rights and standards for resource use, technology, and pollution limits.

Run awareness campaigns to encourage responsible consumption and sustainable lifestyles.

Ban harmful products and promote eco-labeling programs to guide consumer choices.

Invest in research and innovation to develop green technologies and make sustainable choices easier.

Integrate Indigenous and local knowledge systems into sustainability efforts, recognizing cultural values and ethics as essential drivers of behavioral change.

Achieving transformation through synergy

These four strategies are interconnected. Focusing on just one solution is not enough—a balanced approach ensures greater impact and avoids unintended consequences. Combining smart pricing, strong policies, responsible finance, and supportive regulations creates a faster, fairer, and more sustainable transformation of our economic and financial systems.

passed on knowledge and practical skills on resource management, including their observations about environmental change, while also learning about climate change from younger generations and surrounding communities. This facilitated a convergence of traditional and contemporary understandings of climate change, where aspects of Indigenous resource management, land rights, and reduction of climate change impact on their environment as well as resilience-building.

To give a sense of the scale of the value of Indigenous economies, in Canada it is estimated to contribute US$32 billion, with small and medium-sized enterprises, largely nature-based, contributing US$927 million in 2015 (T.D. Economics 2015). In north Australia, on a parcel of land representing less than 1 per cent (29 million ha) of Australia's land area, Indigenous Peoples generated more than US$100 million worth of carbon abatements using their unique knowledge to improve fire management practices (Sangha et al. 2021; Indigenous Carbon Industry Network 2024).

Important messages from these examples include:

- Indigenous economies and conservation can go hand in hand if developed inclusively in participation with locals, in line with local values.
- The value of Indigenous economies is largely invisible, partly because the technical mechanisms for valuing personal, business and national finances do not adequately account for self-management or auto-consumption, nor for exchange or trade through barter, nor for the exchange of knowledge.
- The well-being of Indigenous Peoples – including availability of food, employment, and connections to the landscape is significantly enhanced with the implementation of the solutions-based approach.

Importantly, such a solutions-based approach delivers on 11 SDGs, including reducing hunger and inequity, enhancing incomes, improving health, supporting communities, supporting life on land and shifting local development pathways towards sustainability in the near and long term. In contrast to the Periyar Tiger Reserve example, the general population are reliant on modern economic and political systems. Indigenous value systems and cultural practices can help the wider population enhance their well-being beyond the limits of the current market economy.

14.3 Solution Pathway 1: Internalizing the externalities – correcting pricing

The goal of this pathway is to incorporate external social and environmental costs and benefits into market prices, thereby transforming market forces towards sustainable and circular practices in the production and consumption of goods and services.

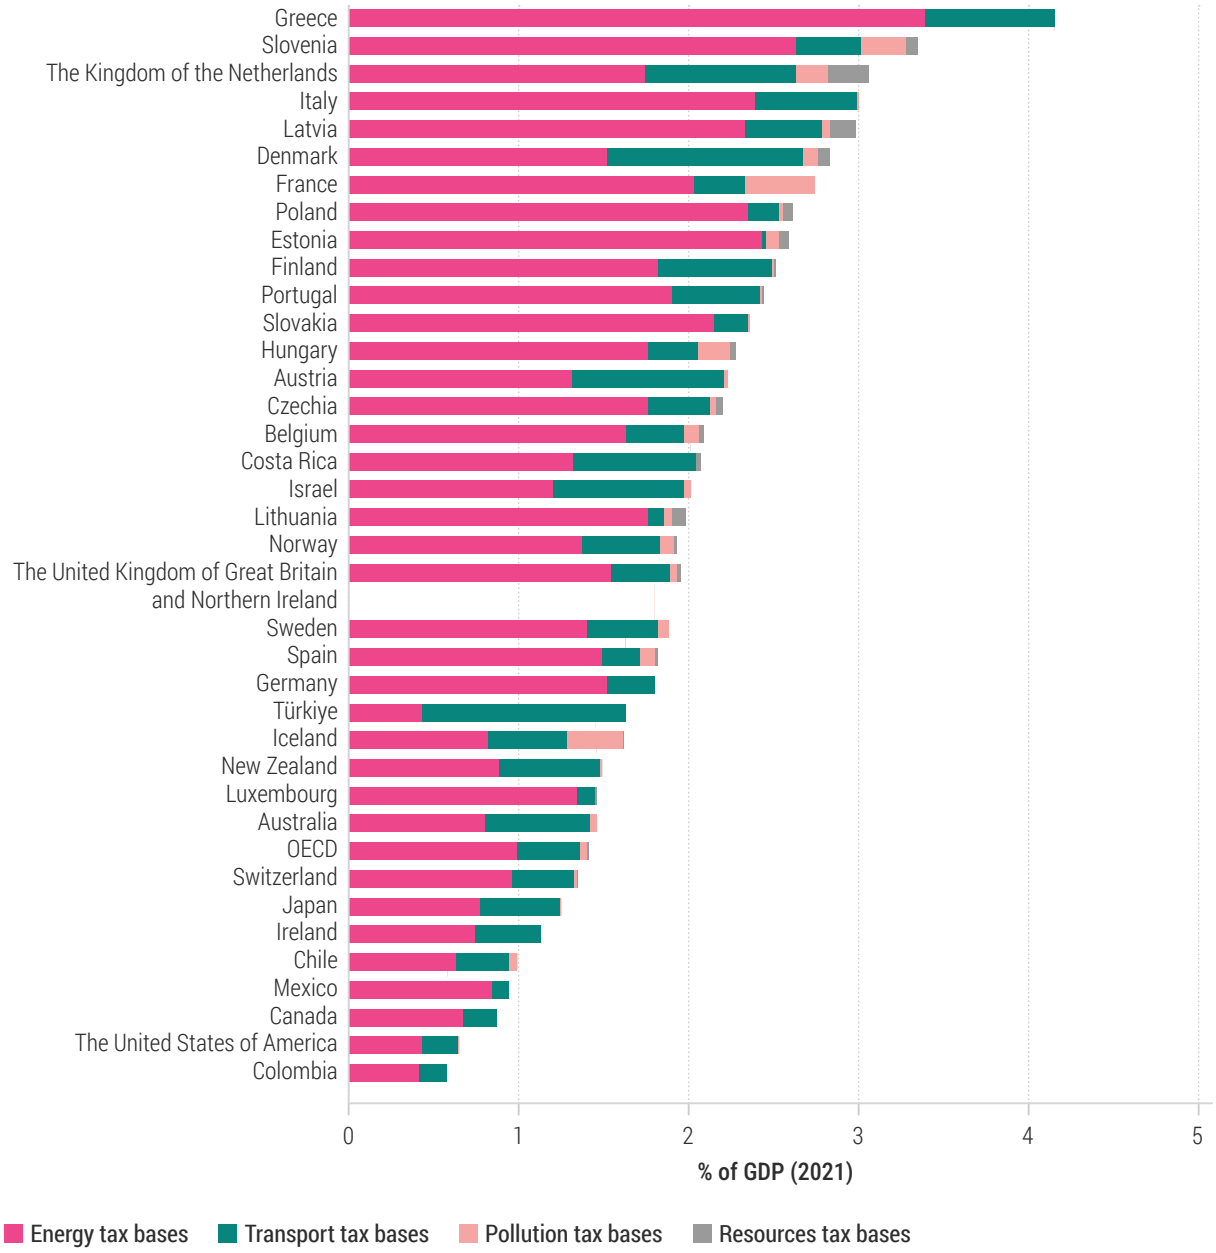
Prices are crucial within economic systems, serving as a mechanism to guide resource allocation, shape incentives and behaviours, promote market efficiency, and signal important information that maximizes opportunities for buyers and sellers without increasing transaction costs while fostering competition. This has not, however, been the case for environmental goods and services where supply and demand outcomes often with excessive production and consumption levels have not always reflected the full social costs and values to consumers or producers, otherwise known as the negative externality problem. To enable a sustainable pathway, proper pricing of resources, materials, goods and services should reflect the value and/or costs to those that directly consume them, as well as the indirect value to other parties that demand and supply interactions fail to incorporate. A simple example would be the burning of coal for energy. The direct value for producers and consumers derives from the energy itself. Yet, there is negative value generated to the environment due to the pollution from burning coal. This includes consequences for the environment that affect people´s well-being in the short and long term that need to be incorporated into the prices to ensure sustainable pathways and reflect the true costs and benefits of burning coal, thereby eliminating market distortions.

The magnitude of the externalities is reflected in the following figures. Current food externality costs are estimated to be almost double (US$19.8 trillion) the current total global food consumption (US$9 trillion). These externalities account for US$7 trillion in environmental costs, US$11 trillion in costs to human life and US$1 trillion in economic costs. As such, food

is roughly a third cheaper than it would be if these externalities were included (Hendriks et al. 2023). In the fisheries sector, depending on the practice, the societal costs reflected by the price of fish vary from 1, for a handline on non-motorboat, to ten times, for industrial bottom trawling (Failler et al. 2022).

The external costs of industrial air pollution from the large industrial operators are equivalent to two per cent of the European Union's (EU) GDP, or US$4.3 trillion (Sovacool et al. 2021). Electricity systems generate US$11.644 trillion in annual externalities and transport another US$13.01l trillion. Combined, this US$24.662 trillion in externalities is equivalent to almost twenty-nine per cent of global GDP. Estimation of the global health cost of mortality and morbidity caused by exposure to $PM_{2.5}$ air pollution is about US$8.1 trillion (World Bank 2022), was an amount equivalent to 6.1 per cent of global GDP, with estimates varying from 1.7 per cent of North American GDP, to 9.3 per cent of the GDP in the East Asia and Pacific regions, and 10.3 per cent in South Asia. Although industrial air pollution in the EU has decreased by about 33 per cent in the last decade, partly due to environmental policies that have placed prices and costs on industrial pollution, industrial air emissions still had an estimated external cost, averaging between US$255–4078 billion per year (European Environmental Agency [EEA] 2024). Social externalities due to water pollution, the main cause of waterborne and childhood diseases, but also poisoning and cancer, correspond to 2.5 per cent of all deaths and 2.9 per cent of all lost days globally (Wolf et al. 2023 and World Health Organization [WHO] 2023). Thus, safe drinking water, sanitation and hygiene could have prevented at least 1.4 million deaths and 74 million days lost to illness, disability and death. Examining the externalities from a climate change perspective reveals that the social cost of carbon emissions is US$1,056/ton CO_2, six times greater than previously thought (Bilal and Kanzig, 2024). The influence of global as opposed to local climate shocks is higher in warm countries that are more vulnerable than temperate ones. Tourism contributes significantly to the generation of externalities. In Australia, tourism taxes also generate externalities, estimated at US$35 per external visitor to Australia, while the visitor tax contribution is only US$25 (Ihalanayake 2013). For the Pacific Island countries, tourism externalities outweigh their net contribution to their GDP (Amardeep et al. 2023).

Hence, the costs generated by the pollution of water, soil, air, flora, and fauna and their global effects, such as ozone depletion, the greenhouse effect, and biodiversity loss, should be incorporated into prices throughout the entire product life cycle (UNEP 2023). Despite this, **Figure 14.5** shows that tax revenue on pollution is low in the selected countries.



Environmental externalities cause direct effects on human health, property destruction, production disruption, and others, including some irreversible consequences for historical and cultural heritage and increased risk of species extinction, which indirectly affect the rest of the economy and human well-being. Price adjustments can be used to correct the value of goods for externalities, and secure progress towards sustainable consumption and production pathways. Pricing adjustments also decentralize decision-making to a degree that allows the polluter or resource user to have maximum flexibility in selecting an appropriate technology for optimizing environmental quality.

14.3.1 Action 1: Selection of the pricing instruments for a policy in development

Prices have a direct influence over consumers, with higher prices deterring consumption and lower prices making consumption easier. Pricing instruments should cover external costs or benefits. In the case of negative externalities, they can be in the form of a tax or charge per unit of either output or pollution, levied according to the external cost imposed on society (an idea originally due to Pigou (1920)), or with market creation approaches where market-wide pollution levels are set and economic agents compete for rights or allowances of units of the aggregate level. Pricing a positive externality can be implemented with direct payments to the providers of environmental services to reflect the external benefit, for example through payment for environmental services (Jayachandran et al. 2016; Wunder et al. 2020). These instruments must also take gender issues into account, as women, along with other marginalized groups, typically have less access to land ownership (Food and Agriculture Organization [FAO], United Nations Development Programme [UNDP] and UNEP 2021), lower incomes (Budina et al. 2023), and less access to technology (Vaishnav 2023).

Externality pricing is applied in a wide range of contexts, including energy production, vehicles and

Figure 14.5: Environmentally related tax revenues in OECD countries

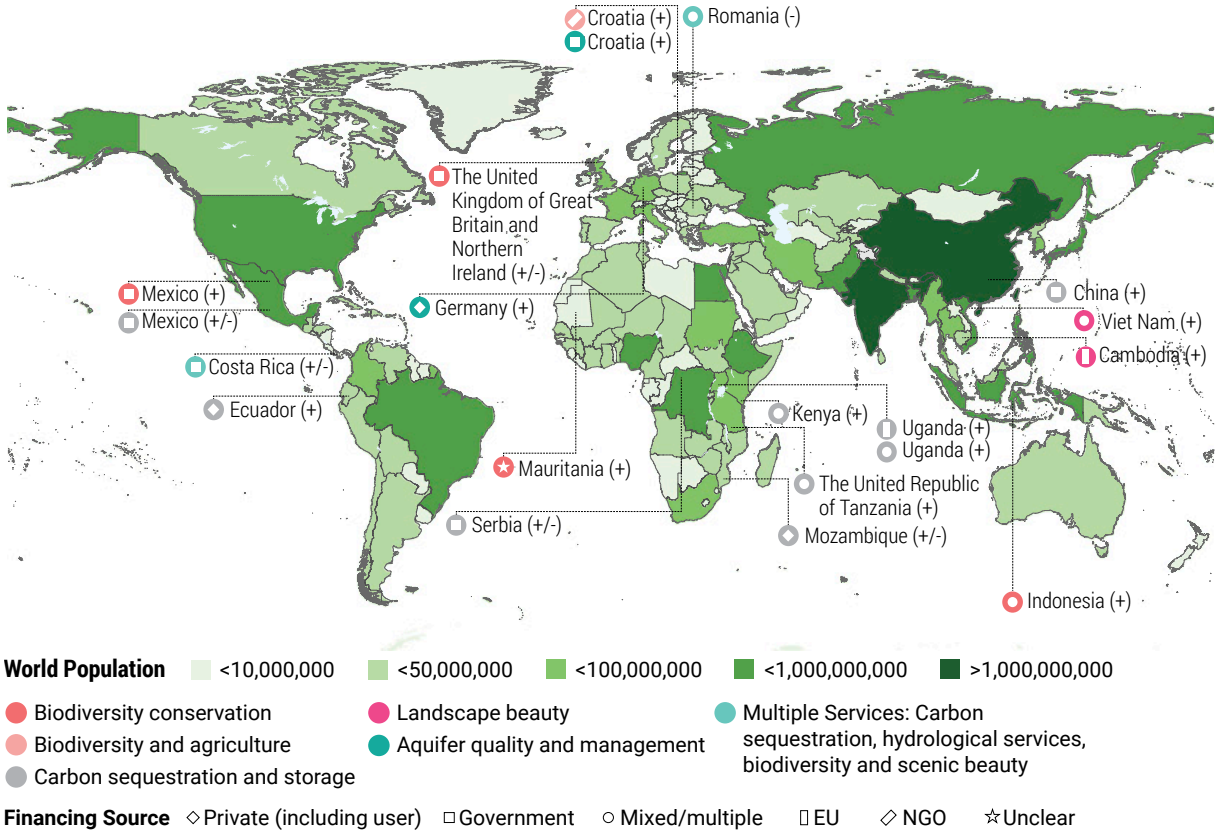
Source: OECD (2024)

transport services; air pollution, ozone-depleting substances, waste management and noise; resource management for water, land, soil, forests, biodiversity, wildlife and fish stocks; and climate adaptation and mitigation. Examples of instruments in practice are captured in the OECD's Policy Instruments for the Environment Database (OECD 2023a). The challenge remains to account for the externalities of illegal activities, such as illegal mining in forested areas in Africa or Latin America, or the effect of groundwater pollution in agricultural areas around the world. More international pressure may be needed from markets that buy, process, or use these minerals, or that engage in intensive agricultural practices.

Transaction and implementation costs are also a parameter for instrument selection. Benchmarking international experiences is important, but application must be tailored to a jurisdiction's unique economic, social and institutional settings. The cost of measuring emissions or the use of emissions creating/reducing services by regulated sources can be high and technically challenging, for example transportation emissions. Consequently, pricing may not always

directly target usage or emissions but instead target the level of an input related to these environmental outcomes, as is the case with fuel and fertilizer taxes. Under such conditions, consumption can proxy for total emission and the effectiveness of the instrument is limited and must be complementary. The required level of externality pricing is determined by the environmental objective and social costs associated with meeting this objective (Bowen and Fankhauser 2017). Action 4 will discuss the institutional setting for such pricing development.

Monitoring and implementation costs may vary across jurisdictions but will be similar for different instruments since each is based on the same pollution levels and effects. In the case of taxation or charges, the fiscal structure is already in place and will need limited legal and institutional intervention to implement new sustainability-focused instruments. In some cases, such as water charges applied by a river basin authority or waste fees introduced by municipal authorities, additional legal and institutional frameworks can be required. There are several variations for each pricing instrument (Baumol and Oates 1988; European Union [EU] 2013; IPCC 2014; Sterner and Robinson 2018; van Essen et al. 2020; World Bank 2023). Taxes may be in the form of either emission taxes, or when emission measurement is difficult, based on input/resource or product taxes, as in the case of automobile emissions and agricultural emissions, with different balances of each used in different jurisdictions (**Figure 14.2**). In some instances, for resource distributors in markets with a concentration of firms for example, taxation downstream of the supply chain can be an option to reduce compliance and monitoring costs. Pricing instruments can also be combined into tax-subsidy combinations, such as fees and rebates, where sales taxes on automobiles can be reduced when vehicle emissions are below a threshold, or deposit-refund schemes, where purchase deposit fees are refunded when item packaging is returned to avoid waste generation. Such schemes can also be fiscally neutral as tax collection equalizes rebates.



Market creation approaches will require developing market infrastructures, regulatory institutions, and legal frameworks to secure trade rights, otherwise economic agents may avoid trading. A cap level on available tradable permit schemes is usually set according to absolute aggregate emission targets. Emission intensity targets can also be an option. Pricing a positive externality via payments for environmental services has been used to target carbon sequestration, watershed services, biodiversity conservation, and scenic beauty (Salzman et al. 2018). Payments for environmental services can be essential to compensating Indigenous systems for their conservation outcomes yet may be reliant on public funding for implementation (**Figure 14.6; Appendix 14.1**). . Participation in these programmes is conditioned by the opportunity cost, direct and indirect, of the financial commitment made by suppliers to offer these services, although uncertainty regarding programme implementation, inertia in changing production modes, and knowledge of the environmental impact from services provided are also important (Grosjean and Kontoleon 2009; Cranford and Mourato 2011; Krishna et al. 2013; Seroa da Motta and Oritz 2018; Aguilar-Gómez et al. 2020; Wunder et al. 2020). In some cases, as the payments for reducing emissions from deforestation and forest degradation in developing countries, the REDD+ programme that targets jurisdictional results over the territory, and not for an individual project, have been adopted to increase the permanence of results and avoid leakage effects of moving deforestation or degradation elsewhere (Angelsen et al. 2018).

14.3.2 Action 2: Compensating for distributional impacts of externality pricing

When environmental services are accurately priced to reflect externalities, unintended consequences for poor households will still need to be addressed. A review of evidence on distributional outcomes of carbon pricing revealed progressive outcomes (Ohlendorf et al. 2021), that is, repercussions that are proportionally higher for lower income groups. The review authors draw attention to the fact that certain approaches can also increase consumer prices and the risk of poverty for low-income households, so revenue recycling schemes should be used to minimize such impacts (Woerner et al. 2024). Evidence of unequal distributional effects due to an inability to pay is also found, for example, in increasing water prices to account for the adverse externalities related to water use (Leflaive and Hjort 2020).

Economic trade and competitiveness concerns must be taken into account when developing environmental regulations and externality pricing. The pollution-haven

Figure 14.6: Examples of payment for ecosystem services implementation in selected countries

Source: See Appendix 14.1

hypothesis argues that firms may prefer to locate in jurisdictions with less stringent environmental regulations where there are lower costs attached to foreign direct investment and business operations. Studies tend to find a minimal adverse effect of environmental regulation on trade and foreign direct investment (Shahbaz et al. 2015; Dechezleprêtre and Sato 2017; Rey and Madiès 2021), while some argue the pollution-halo hypothesis, where foreign direct investment is generally based on clean technology (Mert and Bölük 2016; Gill et al. 2018; Nguyen-Thanh et al. 2022) in a potentially non-linear way (Wang and Wang 2020). Meanwhile equity markets are also displaying increasing sensitivity to emissions trading schemes (Broadstock et al. 2025), even for firms and sectors not directly participating in emissions trading. Despite mixed evidence, concerns about trade competitiveness play an important role in public acceptability of externality pricing (Stiglitz et al. 2017). Therefore, acceptability concerns should be addressed at the instrument design stage and can be managed in different ways, from exemption schemes for externality taxation or some level of free allocation of tradable permits in emissions trading systems or even by increasing the cost of imported goods via border adjustments as taxation and duties. For example, carbon border adjustment mechanisms, which aim to reduce the risk of carbon leakage and to articulate climate policies across jurisdictions, have raised concerns in developing and least-developed countries. The EU introduced a carbon border adjustment mechanism from 2023 and then updated it in 2025 through an associated Simplification Package, which makes it easier for small importers and commits to supporting countries interested in introducing or improving their carbon pricing systems (European Commission 2025a; European Commission 2025b).

Carefully implemented instrument design will require a pragmatic balance between theoretically desirable and practically feasible solutions to increase the probability that these instruments pass into legislation (Schmalensee and Stavins 2017) and also to smooth the structural adjustments in the economy that reduce jobs in high emission sectors that are losing market share in favour of clean activities. It is also important to appreciate that implementation will require a phased approach accommodating what is economically and politically feasible over time. Gradual implementation of externality pricing may be needed to allow market forces to smoothly realign investment and consumption

decisions, with the added benefit of increasing social and political acceptability.

14.3.3 Action 3: Identification and phasing out of harmful incentives

Phasing out and redirecting environmentally harmful subsidies is crucial for the sustainable use of pricing instruments and can also free up a large share of public resources. In today's economies, subsidies have been used to promote consumption patterns aimed at economic goals and unrelated to environmental sustainability objectives, requiring vast amounts of money and favouring environmentally damaging activities (Parry, Black and Vernon 2021). For example, fuel subsidies are used to artificially lower fuel costs so that lower-income households or smaller businesses can afford energy to accelerate their economic growth. Such incentives unfairly distort prices, increasing consumption of environmentally harmful products in direct contradiction to the objective of progressing towards more sustainable economic systems. In short, correcting pricing also requires the removal of some existing incentives that pervert and distort economic activity (Matthews and Karousakis 2022; OECD 2024).

Removing perverse incentives is politically challenging because of the effects on low-income vulnerable households. Such distributive impacts must be fully mitigated, for example, by recycling fiscal revenues from the removal of energy subsidies to compensate vulnerable households (Rentschler and Bazilian 2016; Adekunle and Oseni 2021). Successful experiences of subsidy reform have occurred in the Middle East and north Africa (Rentschler and Bazilian 2016; Adekunle and Oseni 2021).

14.3.4 Action 4: Develop and maintain a centralized coordination of estimated damage and compliance costs associated with the externality to calibrate the pricing levels.

Estimating external costs and benefits is not trivial and requires a substantial amount of data and a varied application of methodological approaches based on predefined assumptions regarding the scope of costs and benefits (Freeman 1979; Bennett 2013). Furthermore, mechanisms to compensate for unintended distributional effects and the removal of harmful subsidies must be integral to the instrument design and will necessitate complementary policy actions. A consistent and validated development framework must be agreed in advance. The framework needs to be designed within a centralized institutional setting to achieve convergence among representatives of civil society affected by the externalities, the private sector, academia and policy-making agencies. Further, the framework should care not only for the design phase, but also the monitoring and evaluation of pricing instruments when in place.

Actions supporting the implementation of the solution pathways for the internalization of externalities will have different time frames, depending on the economic, environmental and social structures of each country. It is recommended that they be implemented sequentially, considering each country's objectives and assessment of the effects of measures on sectors of society, especially the poorest. All this needs to be supported by science and technology, which will help to design projects that use resources more sustainably. For this, governments must make progress in environmental regulation and monitoring (Jayachandran 2022).

14.3.5 Action 5: Expanding comprehensive institutional capacity and preparedness required to implement changes, improvements and coordination among public agencies.

International experiences on externality pricing have demonstrated that the success and permanence of these instruments require early and sustained engagement between government, civil society and impacted stakeholders during the development and design of the instrument. Communication between the fiscal and environmental sectors also needs to be strengthened, not only to ensure proper implementation, but also to ensure that revenues from economic instruments are used to support incentives that benefit the environment (IPCC 2014; Sterner and Robinson 2018; World Bank 2023).

Once the policy objective has been defined and agreed to through engagement with the relevant government agencies and ministries, a possible efficient course of action may be to seek input from international organizations. These may support

the development and implementation of specific policy instruments through the provision of financial and human resources. Environmental agencies could request technical and financial assistance from international agencies to introduce economic instruments, emphasizing the phases and stages where such assistance will accelerate policy adoption.

There is also evidence indicating that women are more likely to engage in pro-environmental actions than men and policy design should take this into account (Zelezny et al. 2000; Berger and Wyss 2021; Tisserand et al. 2022).

Coordinated action within the government and with society, with requested and previously defined cooperation from international agencies, can create the necessary conditions to guarantee the institutional capacity that the use of economic instruments for environmental policies requires. Such coordination and institutional setting are further explored in Solution Pathway 4 on governance.

14.3.6 Action 6: Communication of the instrument to the general public.

Despite its theoretical effectiveness in leveraging the economic system onto a sustainable pathway (Chen, Jiandong and Saleem 2022), there are public concerns about externality pricing coming from firms and individuals. Major public concerns include that pricing externalities may increase production and consumption costs, damaging the economy by decreasing growth and employment, particularly among low-income households and marginalized groups. Some raise concerns that carbon taxes are implemented only for revenue-raising goals. Nonetheless, sometimes, such resistance can be driven by vested interests to limit public intervention in pricing (Hammar, Löfgren and Sterner 2004; Van Asselt and Brewer 2010; Carattini, Carvalho and Fankhauser 2018).

Communication and engagement strategies are crucial for engaging civil society and the private sector, as well as policymakers and legislators, thereby helping to cultivate demand for change in support of proposed policies (Drews and van den Bergh 2016; Baranzini et al. 2017; Carattini, Carvalho, and Fankhauser 2018). Communication strategies to help voters and policymakers understand the social and environmental benefits, including ecosystem services from pricing policies can also nurture people's pro-societal and environmental attitudes and cooperative tendencies, as already shown in studies in behavioural economics and explored further under Solution Pathway 2.

Communication of externality pricing policies must contain clear and coherent information on the total expected benefits and costs, in the short and long run, to whom the benefits will accrue and how distributive repercussions will be alleviated. The rights of local communities must be secured, and their interests must follow equitable, accountable and transparent procedures. For example, asymmetric bargaining power in the voluntary carbon credits market for nature-based projects has adversely affected just and equitable agreements on the sharing of benefits of trade revenues (Healy et al. 2023).

Part of the communication and engagement strategy may include alternative approaches to education. The concept of externalities should be more universally taught, from primary education to higher education, regardless of the specialty chosen at university, and not just reserved for those studying economics courses or for later stages of education.

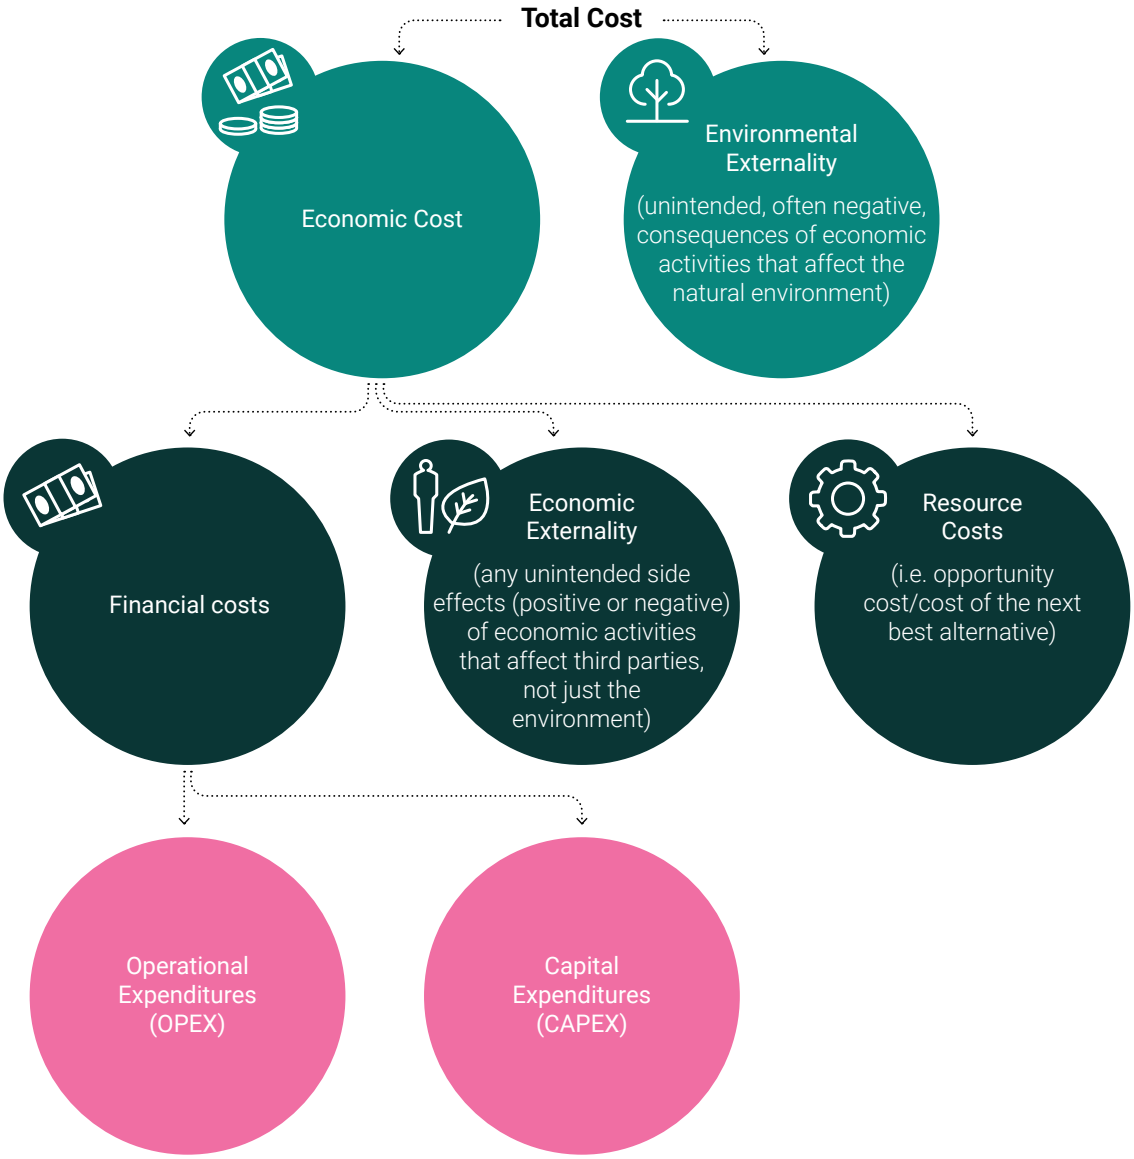
14.4 Solution Pathway 2: Making sustainability core in economic governance

More than half, or 55 per cent, of the world's GDP, equivalent to US$58 trillion, is moderately or highly dependent on nature (PwC 2023), highlighting a material GDP-nature risk exposure. Healthy ecosystems provide essential services such as clean water, food, climate regulation, and disaster risk reduction. By ensuring ecosystem resilience, humanity can achieve significant cost reductions related to climate change, environmental degradation, and resource scarcity. Additionally, healthy ecosystems come with net social benefits related to human well-being and support of vulnerable communities, such as access to resources, local employment and job creation, community engagement and recreational activities. The unique characteristics of ecosystems and environmental resources, such as water as a public good, and of market failures, such as externalities and information asymmetries, render market-based mechanisms alone unable to achieve an efficient allocation of

resources and effective ecosystem management. Chronic environmental failures necessitate a comprehensive approach that extends beyond market-based management of natural resources and ecosystems. Sustainable economic governance, as it has been applied to date, has proven detrimental to the equitable and efficient allocation of environmental resources in an intra-generational, cross-sectoral, and intergenerational manner. Economic governance encompasses market interventions, that is, efficient pricing, the regulatory, oversight and management layers of resource management, the regional, local, and global socioeconomic policies that set the agenda for environmental management in the decades to come, as well as the national, regional, and global actors and the coordination of their actions to support the sustainability transition (OECD 2021). Inclusive governance structures that actively involve Indigenous People, local communities, women and marginalized genders in decision-making processes are essential for normalizing sustainability in economic governance. Inclusive policies can enhance the effectiveness and fairness of governance systems.

Modern economic governance is often characterized by inefficient market interventions such as taxes and subsidies, fragmented policies, and poor coordination at national and international levels. A set of actions is required to achieve sustainable economic governance, as follows.

14.4.1 Action 1: Market interventions for total cost recovery



Deploy coordinated total cost recovery principles for sustainable resource management and allocation: Resource management and allocation through pricing should be driven by the concept of total costs and benefits of resource use, that is, the financial, environmental and resource costs (Barraqué 2020; Burritt and Christ 2021). This necessitates the identification and monetization of these costs (**Figure 14.7**). Moreover, it requires that all resource users and their respective costs and benefits be identified. While the concept of total cost recovery has long been discussed, its application remains fragmented and subject to data limitations. Technological developments and modern information technology tools including artificial intelligence, decision support software, geographical information systems mapping, remote sensing, large data management for environmental accounting and monetary valuation, and integrated models for risk assessment – should be put at the service of total cost recovery to facilitate application (Cox et al. 2023; Ddiba et al. 2023). Total cost recovery may raise social or redistributive issues (Farnault and Leflaive 2024). These issues can be addressed through stakeholder engagement, public awareness, and participatory approaches to resource management.

Implement integrated pricing that considers welfare, efficiency, and the polluter-pays principles: Total cost recovery links to welfare implications, allocative efficiency, financial sustainability of operators, and the ability to produce revenues to compensate for the environmental damages from resource use (Tsani, Koundouri and Akinsete 2020). Methodologically, total cost recovery necessitates data on marginal costs. Basic requirements must be met when choosing the instruments for achieving total cost recovery: ease and affordability of monetization; fair and full cost allocation; and dynamic and efficient incentives. Implementation should be based on the polluter-pays principle, with prices providing adequate and fully informed signals.

Coordinate policies and governance at regional and global levels for sustainable resource management through integrated pricing: An illustrative attempt to implement total cost recovery is the European Union's Water Framework Directive (WFD), Directive 2000/60/EC (European Union, 2000). The WFD is a pioneer systematic approach to water management that addresses simultaneous environmental, social, and economic stressors. The implementation of the WFD coincides with the implementation of the UN 2030 Agenda and EU commitment to meet the 17 SDGs (Akinsete et al. 2019). Article 9 of the WFD requires the total economic cost of water use to be considered. Total cost recovery comes with the advantage of incentive provision for water use and quality protection. On the downside, water pricing comes with opposing views on the objectives that water pricing and tariff design should meet. It is also often the case that water prices are not set in a transparent or understandable manner. This lack of transparency and high complexity often leads to misunderstanding of the real value of water or the aims that are to be met from the revenues collected from water pricing.

Beyond pricing and total water cost recovery, the WFD institutionalizes participatory processes in water-body management in the EU. Governance developments

Figure 14.7: Total cost elements

in the EU highlight existing challenges in the timely implementation of coordinated action across Member States, alignment with the SDGs and the ability to mobilize the required capital to support innovation in the water sector (Tsani, Koundouri and Akinsete 2020). Implementation and monetization of the polluter-pays principal ranges considerably across Member States. Different governance structures and levels apply even within the same country.

14.4.2 Action 2: Implementation of integrated fiscal and macroeconomic policies for just, timely and equitable transition

Addressing the global environmental crises and the transformation of the key systems, such as energy and food, requires moving beyond the fragmented policy systems that remain the norm today.

Implement and fine-tune the global loss and damage concept: Fiscal and macroeconomic policies should be updated and coordinated to serve loss and damage. The loss and damage concept has been discussed heavily in the recent past and it remains a highly politicized topic (Calliari, Serdeczny and Vanhala 2020; Pill 2022). The history of loss and damage and milestone developments, for example, the Warsaw International Mechanism for Loss and Damage, is well known (Roberts and Huq 2015; United Nations Framework Convention on Climate Change [UNFCCC] 2018). Developing nations with the lowest contribution to the climate crisis are the most heavily harmed by climate change, in terms of loss of GDP, cost of mitigation and adaptation, health,

environmental and social consequences, among other aspects (Buchanan and King 2019; IPCC 2022). It is a moral and economic obligation of developed countries to support developing nations for a just, equitable and timely sustainability transition at the global level (United Nations Trade and Development 2022; United Nations Trade and Development 2023). This necessitates delivery on bold financial commitments from developed countries and coordinated global implementation of environment-related fiscal tools such as the carbon tax and global environmental tax.

Coordinated fiscal and macroeconomic policies require transparency and a clear flow of information. Moving beyond GDP measures and conventional accounting is also required. These are particularly important for developing countries that are found at a turning point and require a new growth strategy based on green investment and labour-absorbing services (Rodrik and Stiglitz 2024).

Put debt at the service of environmental targets: The concept of debt-for-nature swaps (DNS) was first introduced in 1984 in response to the destruction of rainforests amid the growing debt of developing countries, particularly in Latin America (Rahim 2020). Debt-for-nature swaps reduce the debt obligation for a country in exchange for the debtor government's commitment to protect nature, thereby facilitating the restructuring of existing debt and supporting green recovery and development. Debt-for-nature swaps can also be used in cases where increased debt financing, as green loans or bonds, would raise debt to unsustainable levels. It is also a way to meet commitments under the Kunming-Montreal Global Biodiversity Framework, which aims to halt and reverse biodiversity loss by 2030, and to meet the SDGs (Yue and Nedopil 2021).

Early DNS examples included a tripartite swap with Bolivia in 1987, led by Conservation International, and a bilateral swap between the Netherlands and Costa Rica in 1989. Since then, more than 100 debt swap operations have taken place, including at least 50 trilateral swaps and approximately 90 bilateral swaps involving some fifteen countries (Chamon et al. 2022). Most swaps have taken place in Latin American countries such as El Salvador, Colombia, Jamaica, Peru, Chile, Costa Rica, and México; in African countries such as Egypt and the Republic of Seychelles; and in Europe's Poland.

Debt-for-nature swaps have helped reduce public debt and protect the marine environment in some Latin American and Caribbean countries in recent years, including Belize, Barbados and Ecuador. However, these operations have been small and have not provided a universal solution for countries facing difficulties related to debt sustainability and nature loss (Guajardo, Ugazio and Chensavasdijai 2023). Increasing the number and size of DNS can help countries strengthen fiscal and environmental sustainability at a time when financing is scarce.

In the Republic of Seychelles' 2015 DNS, the Seychelles government and The Nature Conservancy bought back US$21.6 million of public bilateral debt, mainly from Paris Club creditors, for US$20.2 million, a 6.5 per cent discount (Commonwealth Secretariat 2020). The Seychelles government used private philanthropic funds and loan capital raised by The Nature Conservancy's NatureVest conservation investment unit to purchase the debt through the Seychelles Climate Conservation and Adaptation Trust (Benzaken et al. 2024). In return, the government issued two promissory notes for the same US$21.6 million to repay the Nature Conservancy loan and endow the Seychelles Climate Conservation and Adaptation Trust as the new owner of the debt, which the government will repay over the longer term, providing cash relief on repayments (March et al. 2024). The government committed to protect 30 per cent of its waters, fifteen per cent of its high biodiversity areas, and to adopt a marine spatial plan to guide the updating of coastal zone management, fisheries and marine policies. In line with its commitment under the DNS, since 2015 Seychelles has moved from protecting 0.04 per cent to 30 per cent of its national waters.

Taking into consideration existing experience and to achieve better fiscal and environmental objectives, the following should be implemented:

- Develop a comprehensive bilateral debt swap programme;
- Reduce transaction costs and the time needed to reach agreements;
- Develop debt-for-nature swap agreements in line with the debtor country's conservation objectives;
- Establish agreements between creditors and stakeholders to build capacity and international coordination;

- Support commitment by debtor countries to project implementation and monitoring.

Wide and coordinated green budgeting: Governments and organizations must apply green budgeting widely, that is, integrate environmental and sustainable development targets into their budgeting process, as determined in the Paris Collaborative on Green Budgeting in 2017. This can be implemented through the identification and allocation of resources in favour of environmentally friendly and resilient alternatives. Green budgeting necessitates the prioritization of sustainable projects, full environmental cost integration into market prices, green procurements, and incentives, such as tax allowances and carbon pricing. The EU Green Deal and the US Inflation Reduction Act of 2022 can be referred to as examples of the implementation of green budgeting principles; however, more should be done to achieve a universal and effective design and implementation of these principles. These would need to embrace the increasingly multidimensional nature of green budgeting, requiring more delicate balancing than traditional budgeting where green attributes were historically not considered (The Energy and Resources Institute 2024).

14.4.3 Action 3: Key principles for economic model transformation to benefit people and the environment

Move beyond GDP metrics: To achieve a global balanced path towards sustainable living standards, economies should go beyond GDP growth targets and metrics. Traditional measures of economic growth such as GDP disregard natural resource depletion, biodiversity loss and environmental degradation. A panel of indicators is better suited to assess sustainability, with post-growth and degrowth approaches proposing policy targets and relevant indicators (Creutzig et al. 2022; Hickel et al. 2022; Olk, Schneider and Hickel 2023; Savin and van den Bergh 2022; Savini 2023; van den Bergh and Savin 2023; Vogel et al. 2024). Modern indicators should be based on objective physical parameters such as environmental vulnerability related to climate change (Tregarot et al. 2020) or more diverse development attributes like human development index/indicators that underpin the UN Human Development Reports (UNDP 2024). Modern economies and financial systems should not prioritize economic growth, disregarding the importance of valuing nature in economic planning and decision-making (Dasgupta 2021). Valuing nature does not necessarily come with lower GDP. Sustainability-driven innovation and investments or circular economy models, for instance, can improve efficiency and reduce consumption while promoting economic growth and environmental conservation. Indicators linked to nature-positive targets such as biodiversity restoration can be incorporated in the design and implementation of policies and financial instruments with no environmental or nature-positive effects. Indicators may expand to include ecosystem health, biodiversity, and natural capital values and changes. Frameworks such as the United Nations System of Environmental-Economic Accounting, the System of Environmental-Economic Accounting: Ecosystem Accounting, and the Taskforce on Nature-related Financial Disclosures can help track the contribution of natural capital to the economy.

Reduce inequality: Environmental damage is created disproportionately, with the wealthiest ten per cent accountable for 50 per cent of global consumption emissions (Khalfan et al. 2023). Progressive net wealth taxation schemes can reduce inequality by generating funds for the provision of extended and better-quality public services, as well as financing workers' reskilling required by the socioecological transformation (Tang, Duan and Yu 2023; Betts-Davies et al. 2024; Hou, Liu and Chai 2024;). However, while reducing inequality is essential, doing so may increase consumption among a large portion of the population as low-income households move towards fair and decent living standards, thus the net effects of reducing inequality on the environment may be either positive or negative (Oswald et al. 2021).

Ensure decent living standards for all: Despite population growth, decent living standards across the whole global population could be achieved at 40 per cent of current total energy consumption by 2050, through advanced technologies and demand-side changes to reduce consumption (Millward-Hopkins et al. 2020). Nature-based solutions also promote sustainable ecosystem management at lower long-term costs, while effectively addressing social and economic disparities (UNEP 2022; European Investment Bank 2023).

Increase public investment for the energy transition: The implementation of monetary policy instruments should rebalance financial flows from carbon-intensive assets towards low-carbon assets. This can be done by raising private banks' incentives to lend more for

green investment, as well as by shifting assets and collateral portfolio towards low-carbon assets, for example, mobilizing public finances to redirect or bring in additional private financial capital.

Set sufficiency as a core policy target: A balanced policy mix of incentives, such as subsidies, standards, labelling, and carbon pricing, and progressive taxation can steer production and consumption systems towards higher sustainability. These may send powerful market signals, helping to enable an orderly phasing out of destructive sectors, such as fossil fuels, and the transformation of production and consumption approaches, such as meat and dairy production, fast fashion, and advertising, to better align with circular economy principles.

14.4.4 Action 4: Identification and coordination of core actors at national, regional and global levels

Foster sustainable governance and multilevel cooperation: Developed countries should drive institutional capacity, transboundary cooperation and transparency in methods and approaches. Action should follow coordinated long-term strategic target-setting across countries and regions in a way that links to long-term sustainable development targets. Coordinated long-term strategies can ensure that short-term national deviations will not adversely affect long-term commitments and alignment with global initiatives. While novel ideas and public and private funding may be available, information asymmetries often hinder matching between innovators and funding sources, hampering the innovation process. Governance innovations and updates can improve transparency and upgrade accountability and tracking mechanisms, in turn benefiting financial mobilization.

Identify and coordinate core actors with primary target capital mobilization and coordinated policies for the sustainability transition: Core policy and economic agents operate at different scales and levels local, national, regional, and global, including Indigenous communities, non-governmental organizations, multinational corporations, international financial institutions, central banks, multilateral development banks, international coalitions, organizations and platforms. Related actions should aim to align regional governance with global sustainable development targets and coordinate the mobilization of capital.

Sovereign wealth funds (SWFs) are one group of institutional investors with global influence over the sustainability transition. SWFs are directly or indirectly government-owned and controlled investment funds (Kotter and Lel 2011; Tsani 2013; Aguilera, Capapé and Santitso 2015). SWFs have grown in number from 30 in 2000 to over 100 in 2023 (Sovereign Wealth Fund Institute 2023), and in 2023 had over US$12 trillion of assets under management. SWFs are perhaps the investor class for which it makes most sense to internalize the consequences of climate change, since their long-term investment horizon makes them directly vulnerable to its consequences (Tsani and Overland 2020).

On 6 July 2018, the President of France, Emmanuel Macron, and the Prime Minister of Norway, Erna Solberg, convened a round-table discussion with the One Planet SWF Group, comprising the Abu Dhabi Investment Authority, Kuwait Investment Authority, New Zealand Superannuation Fund, Norges Bank Investment Management of Norway, Public Investment Fund of the Kingdom of Saudi Arabia, and Qatar Investment Authority, with combined assets exceeding US$ three trillion. The meeting marked the launch of the One Planet Sovereign Wealth Fund Framework, aimed at promoting the integration of climate change considerations into the management of large, long-term and diversified asset pools (One Planet 2018). This includes the identification of climate-related risks and opportunities to improve investment decision-making and better inform SWFs' priorities as pivotal financial market actors.

The real-world experience of SWFs reveals several barriers that impede their engagement in green financing activities. These include conflict between long-term green investments and short-term liquidity requirements and between ownership and policy investment priorities and lack of coordination with the budgetary process. Climate policies are high priority in some countries, but not in all countries that operate a SWF.

14.5 Solution Pathway 3: Enhancing financial sector resilience and contribution to sustainability

The goal of this pathway is to strengthen the financial sector's contribution to sustainability efforts, without compromising its resilience to the risks

posed by climate change and environmental degradation. These must be inclusive solutions that also support gender equality and women's access to credit and other financial resources, as well as skills in financial and business management, education and training (Fan et al. 2021).

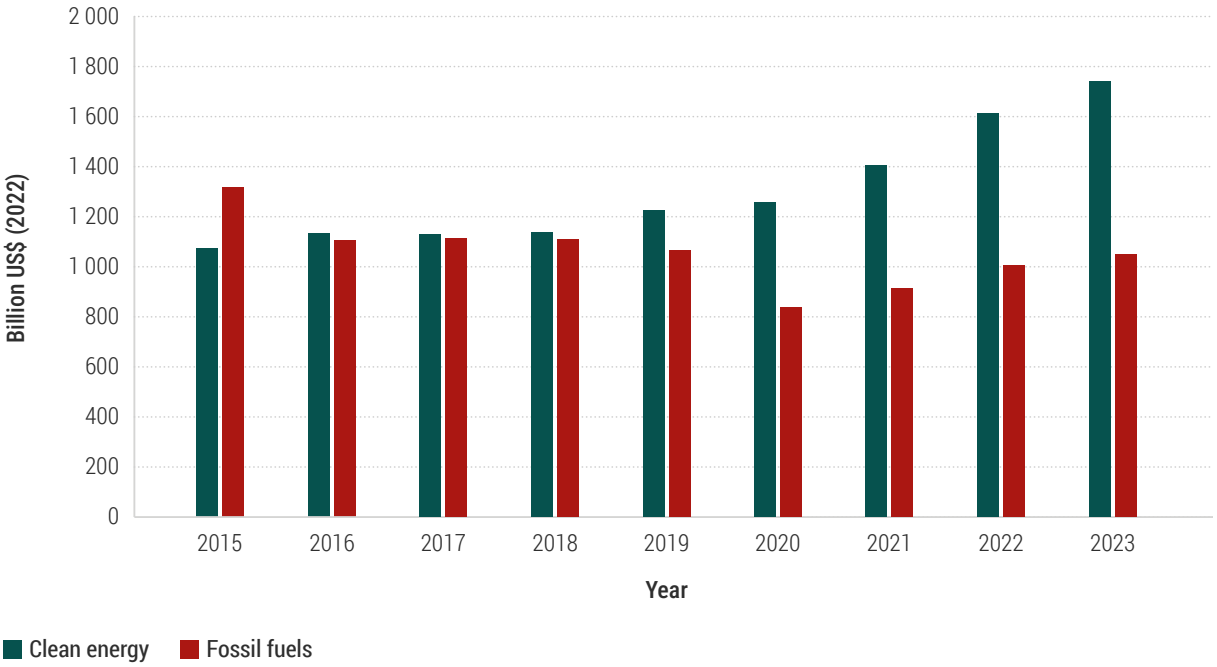
The global gap in finance needed to achieve the SDGs is estimated at US$3.9 trillion per year; yet, among low and middle-income countries, excluding China, there is a concerning downward trend in investment in renewable energy relative to advanced economies (OECD 2022). According to the Global Financial Markets Association (2020), to achieve the Paris Agreement's goals of limiting temperature rise to around 1.5°C, financing will need to exceed US$100–150 trillion cumulatively over the next three decades equivalent to an average global investment of over US$3–5 trillion per year to decarbonize ten sectors responsible for 75 per cent of global emissions. The Kunming-Montreal Global Biodiversity Framework calls for closing a US$700 billion per year biodiversity financing gap and aligning public and private financial flows to be sustainable over time, which is likely to be an underestimate given that it includes only direct effects. In the meantime, the private finance flows that have a direct harmful effect on nature are estimated at US$5 trillion (UNEP 2023).

Financial flows need to be redirected towards activities that ensure better environmental outcomes, limiting the harmful degradation of ecosystems, which threatens food production, a stable climate, clean water and air, and a place for recreation and inspiration (Mirzabaev and Wupepper 2023). The scale of the investment challenge exceeds the capacity of the public sector alone, and the broader financial sector has a pivotal role to play in supporting the transition to a sustainable and resilient future for all, while preserving the stability of the financial system.

Reorienting capital towards more sustainable investments requires a comprehensive shift to place sustainable finance at the core of the system. Traditionally, sustainable finance refers to the process of taking due account of environmental and social considerations in investment decision-making, addressing two urgent imperatives, improve the contribution of finance to sustainable and inclusive wealth by funding society's long-term needs and strengthen financial stability by incorporating sustainability matters into investment decision-making (High-Level Expert Group on Sustainable Finance 2018).

The following actions are recommended to scale up existing initiatives and address barriers to enable a shift in the financial system.

14.5.1 Action 1: Redesign and reorient investment flows towards green activities and projects



Capital markets are the primary source of external finance, channelling vast cash holdings towards investment opportunities. Allocating these resources towards green investments can provide environmental benefits while generating competitive financial returns. Financial institutions are integrating environmental sustainability into the investment decision-making process by placing green debt financing instruments on the market and building a market for green finance. Green finance includes, but is not limited to, climate finance, green loans, green investments and thematic bonds, each described in this section. Other forms of financing, such as debt-for-nature swaps, are described in SP2 and payment for ecosystem services in SP1.

Green loans intend to incentivize businesses that adopt green policies by introducing environmentally friendly services and products through clean energy investments and investments in NbS.

Clean energy investments are a cornerstone action for decarbonization. These typically include funds for research and development of clean energy technologies, construction of renewable energy infrastructure, or adoption of energy-efficient practices and technologies. Investment in renewable energy has increased significantly (**Figure 14.8**), with clean energy growing faster, at 24 per cent than investment in fossil fuels, at 15 per cent, between 2021 and 2023. Nonetheless, estimates point to the need to scale investment to a range of US$150-200 trillion by 2050, with US$5 to 8 trillion per year, while shifting US$1-2 trillion per year from fossil fuels to low-carbon technologies (International Renewable Energy Agency 2023; Allen and Overy and Climate Policy Initiative 2023; Forns Albuixech and Lyubomirova Lazarova 2024).

In 2022, investments in low-carbon energy technologies surpassed a record US$1 trillion, including

Figure 14.8: Global energy investment in clean energy and in fossil fuels

Source: International Energy Agency 2023

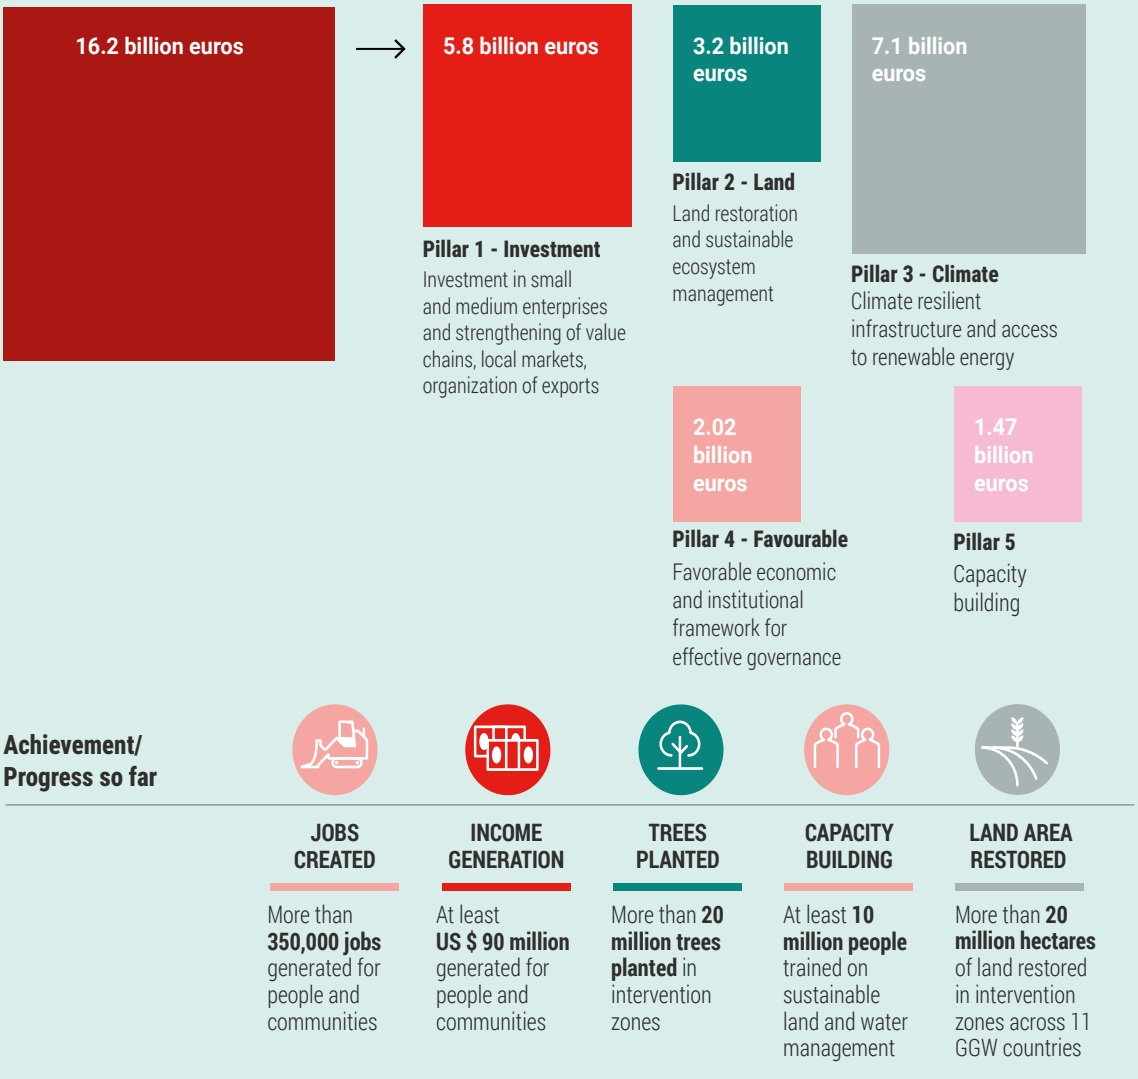
venture capital funding of around US$82 billion (World Economic Forum 2023). However, this was unequally distributed and concentrated in advanced economies and China, something that policymakers will need to address to ensure a secure and broad-based transition.

Around US$770 billion in clean energy investments go towards emerging markets and developing countries each year, albeit concentrated within a handful of large economies. China accounts for two-thirds of the total, and the top three countries, China, India and Brazil account for more than three-quarters (International Energy Agency 2023).

Clean energy investments often require larger up-front expenditures, changing the cost of financing and losing investors' interest, despite being offset by lower operating costs. For this reason, fiscal incentives through tax credits or subsidies can boost business investment in low-carbon technologies, especially if companies are confident about the influence of policies on their investment plans (Black et al. 2023).

Concessional finance is below-market-rate financing provided to developing countries by major financial institutions, such as development banks and multilateral funds, to accelerate development goals (World Bank 2023). To create the conditions for mobilizing as much private capital as possible, the use of concessional finance needs to be expanded, coordinated and carefully timed, particularly in low- and middle-income countries (Damania et al. 2023).

More than half of global GDP is estimated to be moderately or highly dependent on nature (PwC 2023), and therefore, investment flows must align with nature-positive economy goals, ensuring that financial instruments support biodiversity conservation and ecosystem restoration. Financial products, such as biodiversity bonds and ecosystem restoration funds, can help redirect capital towards nature-positive projects, strengthening the financial sector's role in achieving ecological resilience (**Box 14.1**).



The amount currently being invested in restoring degraded ecosystems or preventing further degradation is far less than what is needed. (Mirzabaev and Wupepper 2023). UNEP (2021) estimates that investment in NbS needs to at least triple by 2030 and increase fourfold by 2050, if the world is to achieve the goal of net zero. This implies moving from the current annual investment of US$133.000 million to US$536.000 million per year by

Box 14.1: Nature-based solution (+ adaptation): Great Green Wall (GGW) Initiatives in the Sahara, Africa

The African Union endorsed the 'Great Green Wall for the Sahel and the Sahel Initiatives' in 2007. It brings the vision of combatting climate change and desertification, transforming the lives of millions of people by creating productive landscapes and addressing food insecurity and poverty in those regions (FAO 2014). The project spans 22 African nations, revitalizing thousands of communities by deploying more than US$ fourteen billion in support (UNCCD). The vegetation of the GGW offers numerous benefits: sequestration of carbon, improved water retention, improved soil productivity, shade provision and food for local animals (**Figure 14.9**)..

The Sahel is a hotspot for the increasing threats of climate change. Temperatures are expected to increase by three to six degrees by the end of the century, while precipitation becomes more unpredictable and intense. Precipitation and vegetation rates have increased, while improved water retention and transpiration of plants can accelerate this greening process (United Nations Office for Disaster Risk Reduction [UNDRR] 2023). Cost-benefit estimates indicate that while ten years of land restoration is required to generate market and ecosystem benefits, this project can be considered economically attractive and ecologically sustainable (Mirzabaev et al. 2022). Over 18 million hectares have been restored, with over 350,000 jobs created, as well as US$90 million in revenues generated by 2018.

Figure 14.9: Financial commitments – 5 Pillars, 1 Vision

2050. However,between 2022 and 2023, the increase in annual investment was modest at just eleven per cent (UNEP 2023).

Providing financing in an effective manner requires addressing a range of specific market failures and barriers, including information shortfalls due to a lack of data on the benefits and trade-offs, skills and expertise shortages, a lack of awareness among the general public, a failure in coordination across public agencies, high transaction costs, long time frames for financial returns, and higher risk profiles than other comparable investment options. Where the benefits of implementing NbS do not exceed the internalized costs, increasing private sector investment will require one or more of the following:

- A change in market structures, including regulatory interventions to provide direct incentives for private entities to either deploy NbS or to reduce the environmental impact of their economic activities;

- The development of private markets for public goods, such as extending carbon credit markets to cover biodiversity enhancement or pollution abatement, acknowledging the significant challenges in defining such certificates and credits and administering such markets;

- Co-financing, to blend public funds for public benefits with private funds for private benefits of investments in NbS (European Investment Bank et al. 2023).

Green bonds, alongside sustainability and blue bonds, allow entities such as firms, banks and governmental organizations, to borrow money from investors to finance green projects, assets or business activities. Sustainable debt issuances have grown rapidly in recent years. By early 2024, the Climate Bonds Initiative had recorded a cumulative volume of US$5.4 trillion of green, social, sustainability, and sustainability-linked debt in alignment with its screening methodologies. Aligned green, social, sustainability, and sustainability-linked bonds accounted for US$818.2 billion, an increase of eleven per cent compared to the same period in 2023, at US$738.3 billion (Climate Bond Initiative 2024). Despite this, the market remains small compared with traditional debt markets.

14.5.2 Action 2: Recognize transition finance efforts and align traditional investments with environmental objectives

The sustainability transition pathways of economic actors vary considerably. Transition finance provides support for the broader range of investments required for a whole-of-economy pathway towards sustainability, including assistance to reduce the negative consequences from a disorderly transition, such as transition risks related to the environment or limited access to inexpensive and dependable energy.

Capital markets are already responding to evolving investors' needs, political developments and regulatory changes to support transition financing by developing sustainability-linked debt instruments that operate in similar ways to green debt products, particularly:

- Sustainability-linked loans (SLL) place no limit on the use of proceeds but provide the potential to drive change through financial incentives, aiding borrowers in their sustainability goals by linking sustainability targets and performance indicators with interest repayment schedules. Due to the flexibility of SLL and potential for use across all sectors, they have quickly grown in popularity (UN 2023).

- Sustainability-linked bonds are defined by the International Capital Market Association as "any type of bond instrument for which the financial and/or structural characteristics can vary depending on whether the issuer achieves predefined [sustainability and environmental, social and governance] objectives" (International Capital Market Association 2021). This approach contrasts with the use-of-proceeds approach under SLLs.

- Reorientation and redesign of other traditional financial products: as an example, financial instruments such as insurance products can be restructured to cater for financial shocks in territories vulnerable to climate-induced disasters. Insurance can redistribute the burden of risk and provide fiscal stability as an alternative to bilateral loans that entrench debt. Mechanisms are already in place to

promote such products, for example the UNDP's Insurance and Risk Finance Facility that currently collaborates with 29 countries across Africa, the Middle East, Asia and the Pacific, Latin America and the Caribbean, to leverage insurance and risk-financing solutions to build financial resilience and safeguard sustainable development for vulnerable populations, communities and ecosystems. Within the EU, the ongoing Climate Resilience Dialogue between insurers, re-insurers, public authorities and other stakeholders facilitates an exchange on best practices and identifies ways to address the climate protection gap, either through recommendations or voluntary commitments.

Sustainable infrastructure project investing is especially important in the transition to a more sustainable economic model. According to the OECD, infrastructure contributes about 60 per cent of greenhouse gas emissions (OECD 2017). The world needs to ramp up investments in sustainable infrastructure to tackle large deficits in infrastructure services, especially in emerging markets and developing countries, in response to structural changes that are under way (including urbanization) and accelerating the replacement of ageing and polluting infrastructure. Altogether, around US$6.3 trillion of investment in infrastructure globally is needed every year between 2016 and 2030 to meet global development needs. A relatively modest additional US$600 billion will make these investments climate-compatible (World Bank, 2018).

Given the need for sustainable infrastructure investment, continued progress in developing appropriate frameworks to leverage private investment alongside public funds is key. A wide range of initiatives are under way to enhance the delivery of sustainable infrastructure, including the formulation of the G20 high-level principles on Quality Infrastructure, and to provide tools and methodologies to guide project design and execution (Watkins et al. 2019). Investor confidence is enhanced by strengthening the requirements for labelling financial products as either environmentally sustainable investments or transition finance. Other ways to enhance confidence also include increasing awareness of the environmental impact of financial products, creating visibility, addressing concerns about greenwashing, and establishing standards and requirements to monitor and assess the impact of nature-positive investments.

New approaches and tools should be developed to ensure positive outcomes related to proposed Actions one and two in this section. These include reducing fragmentation between and enhancing the compatibility and interoperability of approaches, allowing for a shared understanding of what environmental sustainability means. Many countries, regions and market actors have recognized the need to establish environmental-sustainability-related taxonomies to help classify financial products. Yet there is a proliferation of standards, principles and frameworks to assess the responsible nature of investments. More than 185 multi-stakeholder initiatives exist, involving 5,181 constituent members (UNEP Programme Inquiry 2015-2021; UNDP FC4S Network; Neto 2021), resulting in confusion and complexity. Global coordination of standards will help reduce adoption costs and overcome the difficult task of navigating various approaches, some of which have limited applicability across different jurisdictions.

The G20 Sustainable Finance Working Group has made a first step towards improving comparability and interoperability by defining high-level principles for countries and markets intending to develop their own approaches. Suggested steps include ensuring material-positive contributions to sustainability goals and focus on outcomes, avoiding negative effects on other sustainability goals, and being dynamic in adjustments reflecting changes in policies, technologies, and the state of the transition. Doing so would further require applying good governance and transparency, adopt science-based assessments for environmental goals setting and other sustainability issues, and address transition considerations (G20 2021).

Sustainability-linked loan principles are increasingly widely used by the capital markets. Developed by the Loan Market Association, the SLL principles set out a framework covering the development of a sustainability strategy, sustainability-related targets and metrics, reporting obligations and external review or verification, enabling financial market participants to have a common understanding of the characteristics of the financial product.

Green taxonomies can be developed through coordination among policymakers, financial market regulators, and other stakeholders. Typically, a government-driven approach is employed to

facilitate mandatory adoption. Examples of this include:

- The government-led taxonomy for China presents a detailed list of eligible economic activities and projects under various sectors and subsectors. Although not technology-neutral, it provides an explicit list of eligible technologies and sets key technical criteria in direct reference to national and international standards. The European Union similarly developed a common concept for classifying economic activities as environmentally sustainable or not.

- The Malaysian taxonomy was put in place by the country's central bank, while in Canada the development of a green and transition finance taxonomy is an external-to-government-led initiative.

- The Government of Colombia developed its Green Taxonomy (Taxonomía Verde de Colombia 2022), establishing how investments can contribute to climate change mitigation and adaptation, ecosystem and biodiversity conservation, water and land management, circular economy, and pollution prevention and control.

- The Government of México, through the Ministry of Finance and Public Credit (Taxonomía Sostenible de México 2023), has presented the Sustainable Taxonomy of México, oriented towards climate change mitigation and adaptation, with a focus on gender equality.

Taxonomies vary in scope: while some frameworks specifically define green investments such as the EU Taxonomy or set up principles for transition finance as in Japan, others embed the transition concept within broader green finance frameworks as Singapore does. As of December 2023, over 51 jurisdictions were developing green investment taxonomies (Marchewitz et al. 2024). Efforts are under way to consolidate different taxonomies to support interoperability. For example, the Common Framework Taxonomy in Latin America and the Caribbean provides guidance for taxonomies in the region, with a focus on climate change mitigation. It provides direction on the inclusion of activities, as well as guidance on the definition of metrics and thresholds for specific sectors of the taxonomy (UNEP 2023). The work to expand the initiative beyond climate change is ongoing, with a focus on conservation, restoration, sustainable use of biodiversity, and ecosystem services.

Sustainable finance products' labels and benchmarks need to be established. Standards and labels can protect integrity and create trust in the sustainable finance market, increasing investor engagement with these products. The most common practices involve clearly articulating the parameters for identifying sustainable investments or measuring the sustainability performance of assets, with the market for green bonds being a quintessential example. Early green bonds were self-labelled by the issuers as green, which was accepted by the market. As the market matured, formal standards and certification mechanisms were developed to validate the credibility of the market.

A market-led approach remains in use. The Climate Bonds Standards, developed based on the governing framework contained in Green Bond Principles, require issuers who intend to launch a green bond to establish a Green Bond Framework, which should align to the use of proceeds for environmentally sustainable activities. This includes putting in place a process for determining project eligibility, management of the proceeds in a transparent way that can be tracked and verified, and conducting regular reporting on the use of proceeds.

Drawing on current best practices, the EU has recently proposed a common framework of rules regarding a European green bond standard that would constitute a basis for high-integrity labelling of financial products. Labelling schemes can be particularly useful for retail investors who would value external verification of the sustainability credentials of their investment's activities. The lack of labelled financial products may prevent investors from directly channelling their funds into sustainable investments.

In addition to labels, benchmarks are indexes that play a central role in the price formation of financial instruments and other relevant assets in the financial system. Benchmarks are useful instruments, as they allow investors to track and measure performance and allocate assets accordingly. Traditional benchmarks reflect the status quo and their methodologies, as a result, reflect sustainability goals only to a limited degree. As such, they are not suitable for measuring the

Credit: williamperugini/Envato

performance of sustainable investments. In response, index providers have been developing sustainability-related benchmarks, including for example climate transition benchmarks, or benchmarks aligned with Paris Agreement targets, introduced under the EU Climate Transition Benchmarks Regulation (EU) 2019/2089 (European Comissions 2020) to capture sustainability goals. However, the lack of transparency regarding their methodologies has affected their reliability. More transparent and sounder methodologies for sustainable indexes are needed to reduce greenwashing risks.

14.5.3 Action 3: Manage sustainability risks at the system level

The financial system is increasingly exposed to climate change, pollution, accelerated degradation of ecosystems and loss of biodiversity, as well as the depletion of natural resources. Financial institutions must become better-equipped to withstand climate-related shocks, which requires coherent and relevant methodologies and tools, as well as capacity building to identify, measure and manage risks at the system level. This includes physical risks from climate change and the loss of biodiversity that can be systemic and hence invisible at the individual asset level. Transition risks may also arise from a disorderly or sudden transition. It is important to determine the nature and account for the degree of these risk exposures, and how they interact and evolve over time (European Commission 2021).

For a balance between ensuring financial stability and allowing the financial sector to pursue environmental sustainability efficiently, strategies to integrate sustainability factors in risk assessment and management in the financial sector need to accelerate. These would be holistic in nature, reflecting both financially material sustainability risks and sustainability impacts.

Sustainability risks need to be integrated into prudential frameworks. While governments should explicitly integrate sustainability criteria into the mandates of central banks, financial markets regulators and supervisors, the latter should ensure the integration of sustainability risks into the prudential framework. Specifically, supervisors should ensure that sustainability-related risks are adequately analysed and captured in their supervisory processes. This requires the development of coherent and relevant methodologies and scenarios to quantify sustainability risks and stress-test the resilience of the financial system.

Credit: akportfolio24 /Envato

Identifying and closing data gaps is key, as the lack of relevant sustainability data is common across jurisdictions. Financial sector experts and environmental experts need to collaborate to address these environmental data gaps. Comprehensive datasets should be built to assess the granular exposure of the financial sector to both physical and transition risk, including cross-border risks.

The Basel Framework, established by the Basel Committee on Banking Supervision, has ensured a globally recognized level playing field on financial regulations applicable to banks with active international operations. The Basel Framework can be adapted to respond to the urgency of the environmental crises and, where possible, the frameworks' Principles for the Effective Management and Supervision of Climate-related Financial Risks (BIS 2022) should be implemented by supervisors through adapted guidance and monitoring. This should consider the specific risk profile of each jurisdiction regarding the environmental effects, as well as the principle of proportionality. The Network of Central Banks and Supervisors for Greening the Financial System has rapidly established itself as a global network of more than 100 central banks and financial supervisors to help accelerate such efforts. Similarly, the International Association of Insurance Supervisors should consider how to integrate sustainability-related risks into insurance supervision.

A more holistic approach can be taken. The financial sector should focus on making all business and investment decisions more sustainable, and account for all positive and negative material effects, as well as risks and opportunities. The use of sustainability due diligence is the key approach for financial institutions to systematically consider and mitigate the influence of clients and investee companies and their supply chains on environmental and social issues. While financial due diligence is a well-established element of financial institutions, sustainability due diligence is based on voluntary schemes. Increasingly, financial institutions are voluntarily considering adverse effects on sustainability issues, referencing internationally recognized frameworks, technical guidelines and good practices (United Nations 2012; OECD 2023b) and incorporating sustainability due diligence in their decision-making.

Due diligence has not yet been sufficiently incorporated in the sustainability risk management procedures of

financial institutions. Information asymmetries, high search costs, and non-disclosure of value-chain relationships and sustainability effects in the supply chain are factors that hamper the ability of financial institutions to measure the adverse environmental and social impacts of their portfolio. These market imperfections can be addressed most efficiently by setting regulatory incentives for financial institutions to exercise corresponding due diligence. Since financial institutions need a level playing field, policymakers may consider legislative intervention to make sustainability due diligence mandatory.

14.5.4 Action 4: Build capacity and strengthen cooperation at the international level

Key actors in the financial sector need to build capacity to adopt financial stability risk assessment and regular stress-testing practices. Strengthening cooperation among all relevant actors regulating the capital market, such as governments, financial regulators, and supervisors, is key to converging approaches and providing the financial sector with usable tools and methodologies. Recognizing the need for global platforms to engage with key financial sector actors and harness the market intelligence of all partners to support the rapid scale-up of green investment and financing flows on a scale commensurate with the challenge, the OECD set up the Centre on Green Finance and Investment in 2016, and the G20 has established the Sustainable Finance Working Group.

14.5.5 Action 5: Foster transparency and long-termism

Investments in environmental objectives require a long-term orientation that is contrary to current market practices, which often emphasize high returns over short time frames. A pivotal challenge for sustainable finance is to reduce undue pressure for short-term performance in financial decision-making through increased adoption of credible, transparent and verifiable sustainability reporting frameworks.

Awareness, strategy, and management of sustainability aspects are no longer enough to meet demands for transparency and accountability. Stakeholders increasingly demand that the financial system align its sustainability interventions with leading performance standards. The evolving sustainability reporting landscape has increased granularity in data, enhanced the metrics with common and clear definitions for performance measurement and forecasting, and nurtures equal rigour in financial and non-financial reporting, and endorsement of environmental commitments by companies' management teams.

The disclosure of sustainability information has improved in recent years with a focus on comprehensiveness and reliability. However, there are still significant gaps and data inconsistencies to be addressed to achieve consistency and comparability of sustainability information across jurisdictions and to avoid fragmentation and the risk of greenwashing (Berg et al. 2022). There are several voluntary disclosure-related frameworks in place, with most of the jurisdictions translating their requirements into mandatory reporting, mainly in the case of climate-related aspects there is the Task Force on Climate-related Disclosure, but also in relation to biodiversity and NbS there is the Taskforce on Nature-related Financial Disclosures.

However, the spur for a more strategic approach to sustainability reporting comes from international policy initiatives that require progressively migrating from principle-based and best-effort basis approaches, to a more standardized, comprehensive, streamlined but granular, as well as forward-looking approach to reporting, based on high-resolution key performance indicators and where a good balance between quantitative and qualitative information is adopted. These can be achieved through the following.

Reflecting the double-perspective of materiality when addressing sustainability–related disclosure. Sustainability reporting hinges on the concept of materiality wherein sustainability factors are reported conditional on them having some material influence on the firm or the environment or both, as is the case in the double materiality perspective of sustainability performance. Existing voluntary reporting frameworks usually employ a single materiality perspective, either impact materiality or financial materiality. Financial system regulators, policymakers and standard setters should support the equal disclosure of sustainability-related consequences, both positive and negative, and risks and opportunities embedded into a comprehensive and coherent framework. The EU is an example case where mandatory disclosure from both perspectives has been introduced.

Ensuring comparability of sustainability-related information. In response to the need for standardized sustainability data, the International Financial Reporting Standards Foundation has established the International Sustainability Standards Board to prepare understandable and enforceable sustainability standards. The Board has already released two exposure drafts that build on the industry-based disclosure requirements and are aligned with the Task Force on Climate-related Disclosure 's recommendations (International Financial Reporting Standards [IFRS] 2022). While largely voluntary, policymakers in certain jurisdictions, including Singapore, Japan and Canada, have begun to translate them into mandatory disclosure requirements. Global consistency and comparability of sustainability information across jurisdictions will reduce fragmentation and the risks of greenwashing (IFRS 2024).

Improving transparency of credit ratings and rating outlooks. Credit rating agencies play a crucial role in the financial system by evaluating the credit risk of both financial and non-financial issuers. Users of sustainability information disclosed by ratings agencies express concerns about the lack of transparency in how ratings incorporate sustainability factors into their methodologies. Therefore, policymakers and international boards such as the International Sustainability Standards Board may take action to improve transparency and regulation over the inclusion of relevant sustainability factors in credit ratings and credit outlooks, while promoting methodological consistency. Achieving this in practice may involve an important layer of coordination between conventional financial ratings providers, third-party environmental, social and governance and sustainability data providers and ratings agencies.

14.6 Solution Pathway 4: Fostering non-pricing approaches towards greening behaviours

In theory, pricing approaches, such as levying environmental taxes and implementing tradable permits, are the most efficient approaches for internalizing environmental externalities. In principle this means that they can realize policy goals, such as emissions reductions, at the lowest social cost. Pricing approaches have been widely used to address environmental pollution issues and allocate natural resources (Stavins 2003; Susswein 2003). However, pricing approaches have not always performed as expected. Evidence of the cost-effectiveness of pricing policies for lowering emissions and protecting natural resources is mixed (Henderson and Norris 2008). Important arguments are being made in favour of complementing pricing with non-

pricing approaches, including property rights responses, regulatory approaches and soft approaches.

Property rights responses include actions to institutionalize ownership of resources and introducing rules for governing behaviours of resource users. Carefully designed combinations of ownership and rules can achieve the desired allocation and use of resources (Starrett 2003). Regulatory approaches refer to the use of coercive power of the state to achieve public goals through influencing the conduct of individuals and firms by setting and enforcing rules (Howlett 2011). Soft approaches refer to less coercive and intrusive interventions, such as information-based approaches, engagement in research and development of green technologies, and fostering voluntary programmes.

Although they can be used in isolation, these approaches are generally seen as complementary to price-based market forces, for example, assigning property rights to individuals or mandating environmental labelling that may reflect different product prices. In considering which approaches to apply, the nature of the externality, the characteristics of the target populations, and the institutional capacity of the government for monitoring and enforcement are important considerations.

The following section outlines a series of actions aimed at encouraging non-pricing solutions towards greening or pro-environmental behaviours. It discusses how various actors, or combinations of actors, are responsible for the success of these approaches.

14.6.1 Action 1: Implement and enforce a coherent property rights system

Regardless of whether rights to the resources are assigned to individuals or collectives, clear delineation and identification of property rights are necessary for reaching agreement on how to allocate resources. Conflict arises only when enforceable property rights are uncertain or ambiguous (Buchanan 1975). Only after property rights are clear can the question of whether the resources should be privately owned or collectively owned be adequately addressed.

If a resource is partitionable and privately owned, it can be efficiently allocated through conventional markets. Under shared, or collective ownership, the collectives owning the resource property rights need to work together to agree access rights for individual collective members. Where resources have uncontrolled collective access rights, overconsumption of resources can occur. This can result in the tragedy-of-the-commons problem that requires government intervention.

When determining whether property rights should be individually or collectively owned, the following points should be considered. First is the issue of equity when market efficiency is taken as the sole value in decision-making. Second, many environmental resources are non-partitionable, making it difficult or impossible to enforce private property rights. Third, spatial fragmentation of resources may impair the effectiveness of using private property rights to address environmental issues (Heller 1998; Buchanan and Yoon 2000; Chasu, Liu and Mu 2023). In addition, there is a potential to introduce what is called a "resource curse" under improper allocation of property rights. This occurs when private resource ownership introduces unfair ownership costs, as in the case of conflicts and disputes over oil resources in the past.

Community-based management of natural resources based on collective property rights can be effective under certain conditions (Ostrom 1990; Agrawal, Erbaugh and Pradhan 2023). Examples include community forest management in the Himalaya region (Agrawal and Chhatre 2006) and community management of irrigation systems in Guangdong, China (Chai and Zeng 2018). Community-based management is a type of self-governance in which the community collectively decides rules regarding access and the use of resources. This can reduce administrative costs; however, the success of such arrangements depends on several factors, including the size of the community.

When managing environmental resources, there is no definitive answer regarding the correct approach to property rights assignment. The nature of the environmental problems, status quo of the rights to environmental resources, legal institutions, customs, and Indigenous Knowledge all matter.

14.6.2 Action 2: Set up technology or performance standards

Establishing standards is a commonly adopted regulatory approach. Standards serve as benchmarks for

compliance and specify sanctions for non-compliance. Two broad categories include technology standards and performance standards. Taking emissions control as the objective, a technology standard might mandate the use of specific technologies or production processes to lower emissions, while a performance standard typically limits the quantity of emissions per unit input or output. Technology standards can be useful when the cost of monitoring emissions is high and confirming adoption of a particular technology is comparatively easy. In contrast, performance standards can be useful when emissions monitoring costs are low and allow polluters flexibility to choose what technology to adopt to comply with the standards. These regulatory tools have been widely used in many countries (Schmitt and Schulze 2011; Greenstone and Hanna 2014; Tanaka 2015).

In designing and implementing technology or performance standards, regulatory agencies need to consult the affected sectors. Sector participants have better information on the availability and affordability of technologies, and the ultimate feasibility of different standards (Pan, Xu and Xue 2023).

Standards have proven effective in limiting pollutant emissions (Singhal 2018), provided that government agencies have the capacity and resources to enforce their use. However, technology standards, which often stipulate specific technologies or equipment that firms must adopt, may introduce costs without providing environmental benefits in some cases. There are also concerns that the use of government-mandated technologies could reduce incentives for firms to pursue innovation and potentially develop more effective technologies (Jaffe, Newell and Stavins 2003; Sterner and Coria 2013).

14.6.3 Action 3: Ban or limit the production and use of environmentally harmful products and services

Banning or limiting the use of environmentally harmful products, technologies or services is another regulatory tool frequently used by governments. For instance, signatory countries to the Montreal Protocol banned the production and use of listed ozone-depleting substances. China banned the use of high-polluting gasoline vehicles that fail to meet certain emission standards (Xiao et al. 2019). Other examples include France's ban on short-haul flights when rail transport is available, while various countries prohibit the open burning of refuse, or prohibit the production, use, import and export of certain toxic substances, as well as place bans on single-use plastic bags.

Bans or limits place firm controls on behaviours and are among the most effective approaches to addressing environmental issues in a timely fashion. For instance, banning the use of high-polluting household appliances such as stoves and replacing them with cleaner technologies can have immediate positive health effects (Seals and Krasner 2020; Gruenwald et al. 2023). However, this regulatory approach could be very costly if affordable substitutes are not readily available or if the required infrastructure is not in place. In many developing country settings, lack of electricity in rural areas may make it challenging to switch from dirty cooking fuels to cleaner options.

When deciding to ban or limit the production and use of environmentally harmful products, regulatory agencies must assess the social and economic effects of such decisions. Bans and limits can directly affect individuals' jobs or incomes, and businesses and individuals need enough time and flexibility to adjust. Where there are concerns that bans may interfere with individual choices and preferences, public awareness campaigns should be organized to explain the rationale. Government assistance for vulnerable businesses and individuals or households may be necessary.

Bans or limits can be designed to limit the cross-border exchange of environmentally harmful products. For example, the EU's Deforestation Regulation (European Commission 2023) prevents products associated with deforestation and forest degradation connected to certain commodities, such as cocoa, coffee, palm oil, rubber, soy, wood, and cattle, from entering the EU market, thereby discouraging environmental degradation in producer countries.

14.6.4 Action 4: Set up labelling programmes to influence consumers' choices

Environmental labelling programmes aim to influence people's choices in markets, to enhance awareness and diminish consumption of goods that are more environmentally harmful (Camilleri et al. 2019; Taufique et al. 2022). This approach involves the use of a simple and easy-to-understand signal, such as

a logo or seal; a quantitative declaration, such as energy consumption per unit of time; or a textual claim (OECD 2016), to inform individual and organizational choices. Environmental labelling schemes have been developed and managed by public agencies, private sector actors, and non-profit organizations. The label may reflect natural resource use, waste generation, biodiversity impacts, environmental pollution potential, climate impacts, energy consumption, and agricultural practice, individually or in combination. It can be mandatory or voluntary, and potentially externally certified. It should be non-misleading and non-discriminatory. A salient example is energy efficiency labelling on commonly used products that may consume large amounts of energy, such as refrigerators, air conditioners, or residential gas boilers.

Challenges with this approach are notable. First is the potential for greenwashing, where companies profit from sustainability-oriented consumers by making misleading and potentially false statements about the environmental benefits of their products (Shahrin et al. 2017). Second, this approach can require extensive education and awareness campaigns to overcome low consumer awareness, concern, interest and even trust in the implications of attached labels (Feucht and Zander 2017). Third, corporations, whose profits are greatest for products with the largest carbon footprints or adverse biodiversity effects, may be more resistant to labelling efforts. Fourth, empirical evaluations of labelling schemes' effectiveness do not provide a clear gauge on the effects of carbon, biodiversity and energy labelling on actual purchasing and consumption behaviours in different settings.

14.6.5 Action 5: Conduct information campaigns to promote environmental attitudes and behaviours

At any given time, individuals and firms face multiple, sometimes conflicting, interactions with environmental issues. They may be victims of environmental problems and wish to take protective measures. They may at the same time be contributors to environmental problems through their consumption patterns and need to adopt pro-environmental behaviours. They can serve as stewards in identifying and reporting environmental violations. They may express support or opposition regarding environmental policies. These can all be daily behaviours. The motivations and payoff structures for each of these types of behaviours are quite different, and thus, the level of difficulty in motivating pro-environmental behavioural change quickly becomes a very complex problem. In such conditions, information campaigns can be preferable to regulations in motivating desired behaviours and nudging social norms, as they are non-intrusive approaches and retain people's liberty of self-constraints on their behaviours. Studies suggest that social influence and shifting social norms in favour of environmental conservation can reduce emissions (Horne and Kennedy 2017) and motivate sustainable actions (Schneider and van der Linden 2023). One caveat is that there should be adequate, affordable and accessible substitute products available in the market.

Information campaigns for public goals are often initiated by government agencies as well as non-government organizations. For instance, many local governments use public information campaigns to raise awareness of the risk of polluted air to change people's responsive behaviours towards polluted air (Henry and Gordon 2003). In designing and transmitting messages, the psychological aspects of messages, local knowledge, the educational background of the target audiences, and the accessibility of the audiences to different information channels need to be fully considered to enhance the effectiveness of such measures. When conducting information campaigns, it is desirable to assess the pros and cons of sustained versus episodic campaigns. While the former may foster long-term change, the latter may be less costly.

14.6.6 Action 6: Engage in and support research and development of green technologies

Research and development in green technologies carries as much importance as promoting green behaviours among firms and individuals. While green financing from the private sector can help facilitate the deployment of green technologies, early-stage fundamental research for untested technologies benefits from government intervention. Moreover, there is an unequal distribution in technology use between developed and developing countries, where developed countries take the lion's share of the benefits of green technologies (United Nations 2023). For developing countries to benefit, they need to place substantial effort on building domestic capacities and installing supportive industrial and innovation conditions.

Assessing the effectiveness of non-pricing policies or actions is challenging, since their effectiveness is related to their specific design, as well as their enforcement. The simultaneous use of pricing and non-pricing instruments makes it difficult to disentangle the respective contributions each provides in reducing emissions. Nevertheless, some general conclusions can be reliably drawn.

If designed and implemented carefully, banning or limiting the production and use of environmentally harmful products will be effective in reducing environmental damage. Using standards to regulate individual and firm behaviours is expected to be effective. Maintaining vigilant oversight and attribution of property rights will help allocate resources efficiently. However, the effectiveness of information-based approaches such as environmental labelling and information campaigns is less certain, with many factors affecting people's behaviours. There have been synthesis findings showing that information campaigns significantly improved global conservation outcomes, complemented by evidence that non-price policies aimed specifically at renewable energy, fuel efficiency, electrification of passenger vehicles, and forestry have successfully been implemented in China, EU, India, Japan, and the United States (Green et al. 2019; Fekete et al. 2021). Drawing reference on the use of Nature-Positive Initiative metrics may be helpful for designing or assessing the effectiveness of non-pricing approaches to foster biodiversity-positive behaviours.

It is worth noting that studies have also shown that gender-related beliefs correlate with differences in pro-environmental behaviours, with green consumption choices and with other environmental intentions (Zelezny et al. 2000; Swim et al. 2020). Non-pricing approaches should therefore consider gender differences in behaviours and ensure that environmental programmes and interventions are tailored to be inclusive for all genders.

14.7 Combining solutions to achieve the goals

To reach and maintain transformative, inclusive and nature-positive change in economic and financial systems requires the implementation of combined solutions. Depending on a single solution pathway would be inefficient at best and ineffective at worst. Adapting over time and remaining open to switching between or reconfiguring the relative balance of importance of the various solution pathways will be crucial for ensuring effective change. Combining solutions to achieve economic transformation must include Indigenous People and local knowledge, as well as gender perspectives to ensure that all can benefit equally from sustainable development initiatives. Integrating these different considerations as early as possible can enhance the effectiveness and inclusivity of combined solutions.

Individual solution pathways will be strengthened by co-development of other supporting pathways. As such, possible synergies between the solution pathways are not only to be recognized but should be exploited. Moreover, simultaneous implementation of solution pathways is sought to adequately and promptly address facets of supply, demand, and system governance, to ensure that the development and implementation of actions and policies involve the relevant actors and stakeholders.

For instance, internalizing externalities (SP1) such as environmental damage from production works in tandem with green finance (SP3) tools such as environmental, social and governance rating, while also fulfilling a growing consumer demand for greener products (SP4), which is often achieved through well-structured macro-governance systems (SP2).

The key questions to consider are:

- Which pathways positively support the implementation of other pathways and how?
- Which pathways are incompatible with other pathways?
- Which pathways take longer to implement for sequencing considerations?
- Which pathways require social engineering or education campaigns?
- Which pathways may be contentious from a political perspective?
- Would implementing all pathways in parallel be the most effective strategy?

Table 14.1: Synergies and trade off which other systems.

Economic and financial solution	Energy Systems	Food Systems	Environmental Systems	Circularity
Fiscal tools Expanding externality pricing; Phasing out and repurposing existing subsidies and environmental taxes.	This solution will encourage the choice of cleaner alternatives such as renewable energy and energy efficiency, particularly for low- and middle-income countries that have difficulties in mobilizing the necessary financing (World Bank 2023).	This solution would improve fish stocks and achieve more sustainable agriculture (Damania et al. 2023).	This solution will be important in environmental systems to reduce the effects of water, soil and air pollution, greenhouse gas emissions and to avoid the loss of natural capital.	Revenues from the repurposing of subsidies can be used to promote the circular economy.
Making sustainability core in economic governance	This allows increased public and private investment for the energy transition.	Clear government signals will increase sustainable management of terrestrial and marine food production.	Sustainable economic governance helps combat biodiversity loss, climate change, pollution and land degradation.	Positive effect in accelerating and maintaining all aspects of economic circularity.
Enhancing financial sector resilience and contribution to sustainability: Promoting public and private investment in NbS, restoration of ecosystems, and climate change	This solution will modernize the energy mix, moving away from fossil fuels and increasing efficiency in energy distribution and use.	This solution could have a positive effect on agricultural land restoration and increase land production.	This solution could increase territorial and marine protected areas, avoid deforestation and wetland loss, and enhance the ecosystem services.	This solution will contribute to natural resources conservation, such as metal and biomass. It will also contribute to the strengthening of efforts to reach a nature-positive, regenerative form of economic circularity.
Non-pricing approaches	This will allow reduced energy consumption, more energy efficiency and the development of renewable energy.	The influence of these tools on the food system will make it possible to achieve sustainable agriculture, a reduction in land degradation and the production of healthier food.	The environmental benefits will be emission reduction, increased biodiversity, less pollution, and decreased land degradation.	Will foster social acceptance and behaviour change, helping to reduce material consumption and increase the recycling and reuse of materials already in economic circulation.

- While reviewing such questions it is also important to be mindful of overlapping questions or synergistic solutions that exist across different systems.

14.8 Synergies

Table 14.1 presents synergies among the four solution pathways for the transformation of economic and financial systems, and how they intersect with priorities and solutions in the energy, food and environment systems (Chapters 7, 16, 17 and 18) as well as circular systems of resource use (Chapter 15). These other systems are both components and users of economic and financial systems, and the full range of system-specific synergies is necessarily expanded within the respective systems chapters to ensure sector-specific nuances and insights are properly presented in context.

Solution Pathway 1 focuses on the actions necessary to accurately price externalities, including the elimination of environmentally harmful subsidies. Certain subsidies, such as fuel subsidies, when removed, will have direct and immediate effects on the energy system, likely helping to accelerate the adoption of electric vehicles into the mainstream, and the move to low-carbon electricity. Other systems will also benefit, particularly through the recycling of revenue from emissions pricing

schemes to nurture economic circularity and support nature-regenerative projects.

Solution Pathway 2 relates to multilevel and multilateral governance, macroeconomic and fiscal policy considerations. Synergies will arise from adopting integrative governance approaches to steward natural capital and resources with closer participation from Indigenous Peoples as well as local communities. Additionally, revised governance will help the uptake of circular resources systems, which will require expanded oversight relative to conventional linear consumption-based economies. Synergies among economic, environmental, and social systems must include Indigenous People and local communities, as well as gender considerations, to maximize the benefits of sustainable development for all members of society.

Solution Pathway 3 places an emphasis on financial sector tools and frameworks to unlock private financial capital for environmental sustainability projects. The most urgent changes will include frameworks for consistent, transparent and reliable valuation of NbS and biodiversity projects, where the current information gap is arguably the greatest. Benefits will accrue to all other systems, given the traversal role of project financing and requirements for the monitoring and oversight of investment activities across all parts of the economy.

Solution Pathway 4 concerns the role and use of non-price instruments to foster pro-sustainable norms, attitudes and behaviours. These will complement the other solution pathways and actions and can be applied across all sectors in varying configurations. Within the energy sector, for example, labelling is already widely applied and is likely to remain in place, sustained by technology support packages of different sorts. In food systems, information campaigns might be a strategy for promoting the adoption of alternative proteins. For environmental systems, there is a need for greater understanding of the dependence of natural resources in our economic systems and the adoption of value principles from Indigenous Peoples as well as local communities in stewarding and regenerating natural capital and promoting economic circularity.

Appendix 14.1:Additional detail on examples of payment for ecosystem services implementation in selected countries

Ecosystems service	Biodiversity conservation
Country applied	Indonesia
Reference	Kurbjeweit. B. (2022)
Funding	Mixed
Outcome	**Positive**. The payment for ecosystem services (PES) application allows for the conservation of forest and wildlife species in Nanga Lauk and the diversification of economic activities.The agreement with the companies guarantees income for the ecosystem services provided by the project for 25 years from 2019.
Country applied	México
Reference	Costedoat et al. (2015)
Funding	Government
Outcome	**Positive** México's PES programme for biodiversity conservation enabled greater protection of forest cover.
Country applied	United Kingdom of Great Britain and Northern Ireland
Reference	Alston, et al. (2013)
Funding	Government
Outcome	**Mixed**. The UK PES programme has seen a significant increase in the area covered. Most of the enrolled producers have relatively small farms. This is not the case for producers on larger, highly industrialized farms that receive more agricultural subsidies.
Country applied	Mauritania
Reference	Binet et al. (2013)
Funding	EU through fishing agreement
Outcome	**Positive**. The Banc d'Arguin National Park is using the European Fisheries Agreement as a PES to support the conservation of coastal biodiversity and to re-establish the link between fisheries and the management of marine protected areas. The results are positive, with sustainable long-term funding, adequate payments and livelihood benefits for local communities.

Ecosystems service	Biodiversity and agriculture
Country applied	Croatia
Reference	Capodaglio, and Callegari (2018)
Funding	No data
Outcome	**Positive**. Lonjsko Polje is an area with higher biodiversity. Land abandonment is high in these areas. PES is an incentive to avoid land abandonment and to maintain biodiversity.

Ecosystems service	Carbon sequestration and storage
Country applied	Kenya, Uganda, The United Republic of Tanzania
Reference	Osewe et al. (2023)
Funding	Mixed
Outcome	**Positive**. PES in these countries have increased the efficiency of ecosystem services (ES) conservation and benefited poor rural communities.
Country applied	Uganda
Reference	Jayachandran et al. (2016)
Funding	No governmental organization
Outcome	**Positive**. The PES programme in western Uganda offered cash payments to forest owners for conserving their forests. Tree cover decreased by only two to five per cent with PES, and by seven to ten per cent without PES. It had a positive effect on carbon sequestration.
Country applied	Mozambique
Reference	Alston et al. (2013)
Funding	User (international carbon payment)
Outcome	**Mixed**. The Carbon Livelihoods Project in Nhambita has made it possible to reduce agricultural activity and deforestation, adopt better production techniques and increase incomes. The disadvantage is that transaction costs are high.

Country applied	Serbia
Reference	Keca, and Marković, (2019)
Funding	Government
Outcome	**Mixed**. The Forestry Fund is a separate line item in the national budget that finances the increase of forest cover through afforestation. Afforestation is not necessarily a biodiversity-friendly activity. In some cases, valuable and biodiversity-rich forest areas have been reforested with species for intensive timber use.

Country applied	México
Reference	García Romero (2012); Reyes-Hernández (2023)
Funding	Government
Outcome	**Mixed**. This PES programme did not have a significant impact on preventing deforestation. The main problems were unclear selection criteria, failure to calculate opportunity costs for different ecosystems and failure to consider the risk of deforestation.

Country applied	China
Reference	Salzman et al. (2018); Chen, et al. (2020)
Funding	Government
Outcome	**Positive**. China has the Slope Land Conservation Programme to convert steep farmland into forests and grasslands and the Natural Forest Conservation Programme focusing on logging bans and afforestation. Assessments have found that all ecosystem services except biodiversity habitat have increased, with mostly positive socioeconomic benefits.

Country applied	Ecuador
Reference	Alston et al. (2013)
Funding	User
Outcome	**Positive**. The PROFAFOR project in Ecuador monitors individual plots of land to evaluate forest cover.

Ecosystems service	Landscape beauty
Country applied	Viet Nam
Reference	Nguyen et al. (2020)
Funding	Mixed
Outcome	**Positive**. Solutions have been successful in reducing forest cover.
Country applied	Cambodia
Reference	Milne and Chervier (2014)
Funding	Conservation organizations
Outcome	**Positive**. Cambodia has an extensive PES programme. One of these is community-based ecotourism in Preah Vihear to protect endangered bird species and their ecosystem. Bird watchers pay a fixed fee to a village committee, which collectively distributes the benefits to villagers. This encourages the creation of local natural resource management institutions.

Ecosystems service	Multiple services: carbon sequestration, hydrological services, biodiversity and scenic beauty.
Country applied	Costa Rica (Since 1987)
Reference	Alston et al. (2013)
Funding	Government
Outcome	**Mixed**. The programme has multiple objectives, making it difficult to assess the effectiveness of any one service. In terms of deforestation, there is no discernible difference in forest cover between participants and non-participants. Two studies show that land tenure has become more secure. The economic impact was found to be negative and the poor did not benefit.
Country applied	Romania
Reference	Capodaglio, and Callegari. (2018)
Funding	Public and Private
Outcome	**Negative**. The Oas-Gutai plateau area is rich in natural biodiversity and picturesque landscapes. The problem in the area is overgrazing and land abandonment. Payments have not been sufficient to fully cover costs and therefore have not solved the problems.

Ecosystems service	Aquifer quality and management
Country applied	Germany
Reference	Le Coent (2023)
Funding	User
Outcome	**Positive**. In response to increasing pollution of drinking water resources, the city of Munich developed a PES for farmers in the catchment area. Eighty per cent of the area was covered by the programme, which improved water quality at minimal cost to users.
Country applied	Croatia
Reference	Vuletić et al. (2019)
Funding	Government
Outcome	**Positive**. Subjects pay a percentage of their annual income for forest ecosystem services that affect water purification and the supply of drinking water from underground watercourses and water sources.

Chapter summary

Credit: siwabudv/Envato

A global shift to a circular economy is a leading solution to the interconnected environmental crises of climate change, biodiversity loss and land degradation, and pollution and waste *(well established)*. Maintaining stocks of materials and a circular flow of resources in the economy will also contribute positively to socioeconomic development while safeguarding nature and people {15.1.3}.

The GEO-7 target-seeking scenarios show that by 2060, a circular economy can achieve a global material demand peak below 120 billion tons per year, compared to a business-a-usual scenario of extraction rates exceeding 160 billion tons per by 2060 *(established but incomplete)*. By combining technological innovations and behavioural changes that increase material circularity, the world can reduce global primary material demand {15.2}.

Global plastic pollution is worsening and 8000 Mt of plastic waste pollute the planet while production is projected to increase from 475 Mt in 2022 to 1200 Mt by 2060 *(well established)*. Plastic pollution is the cause disease and death and are responsible for health-related economic losses exceeding US$1·5 trillion annually. (well established) {15.1.1}.

In contrast, a circular economy approach can help to address these issues an 80 per cent reduction of plastic waste by 2040 can potentially generate net savings and avoided external costs of US$1.2 trillion per year, US$18 trillion cumulatively over the next 15 years *(well established)*. A circular economy approach addressing the global municipal waste crisis could generate a projected annual full net gains of US$108.5 billion by 2050 through waste avoidance, circular practices and full waste management. Downstream solutions such as recycling and waste management alone are not sufficient to tackle plastic pollution. In addition, a combination of upstream solutions and regulatory measures to reduce unsustainable production and curb plastic demand through eco-design, reuse models, remanufacturing

and product repair is the most cost-effective pathway to eliminate plastic pollution {15.2.1, 15.2.5}

Beyond eliminating waste and pollution, the circular economy can create new economic opportunities *(established but incomplete)*. Multiple studies and economic modelling across regions demonstrate that the circular economy can drive job creation and economic development across key industries such as manufacturing, construction, transport, food and services by fostering resource efficiency, innovation and new business models in both developed and developing countries {15.2.1}.

Between 30 and 58 per cent of the demand for critical energy transition minerals, such as lithium, cobalt, nickel, manganese, rare earth elements, platinum and copper, could be met through secondary supply and circular economy practices by 2050 *(established but incomplete)*. The circularity of critical energy transition minerals will be essential in reducing the to: the growing demand for primary minerals and declining the need for primary mining {15.1.6}.

Electronic waste recycling offers significant economic opportunities for the recovery of critical materials. An estimated 62 million tons of electronic waste was generated globally in 2022, with a global market potential of US$65.8 billion by 2026 *(well established)*. In addition to increasing recycling rates of the various minerals and metals used in digital technologies and renewable energy systems, circular economy practices such as lifetime extension, refurbishment and recovery, as well as material substitution, will be essential {15.2.1; 15.4}.

As of 2024, a total of 75 national circular economy road maps have been launched, from 4 road maps that existed in 2016, and more are under development. *(established, but incomplete)*. These road maps include a collective commitment from governments to introduce just under 3,000 circular economy policies spanning 17 sectors, making this one of the fastest-growing environmental policy categories worldwide over the next decade. However, these road maps are currently insufficient to drive transformational change at the scale and pace needed to reduce pressures and impacts on natural systems {15.2, 15.3.1}.

Circular economy solutions are critical to achieving climate change mitigation targets in high-impact economic sectors *(well established)*. Businesses and value chains with high environmental footprints, including for hard-to-abate sectors such as steel, cement, chemicals and batteries, depend on the successful implementation of circular economy strategies {15.1.6}.

Circular regenerative practices in agricultural and food systems can contribute to reducing waste and pollution, preserving and restoring soil health *(well established)*, as well as protecting biodiversity and achieving nature-positive outcomes *(established but incomplete)*. Such practices include nutrient cycling, regenerative agricultural practices, and Indigenous practices in agriculture and food systems {15.2.2, 15.2.5, 15.2.6}.

Circular practices are instrumental in preventing negative effects of the bioeconomy *(established but incomplete)*. Shifting from non-renewable resources to biobased materials can reduce environmental pressures associated with the extraction and use of materials, but safeguards are needed to ensure that substitutes have lower adverse impacts throughout their life cycle. Integrating nature-positive solutions into these models can ensure that economic activities actively regenerate and enhance natural ecosystems {15.2.6}.

Rights-based approaches are needed to ensure equitable, socially just, sustainable outcomes for the circular economy and for the protection of biodiversity *(established)*. It requires free, prior and informed consent, accountability measures, and full and effective participation of Indigenous Peoples to safeguard their rights on lands, waters and territories and to sustain their biocultural, customary practices, Indigenous Knowledge and Local Knowledge systems {15.2.2, 15.2.5}.

The following five solution pathways are proposed:

1. **Designing out waste from production and consumption by designing in circularity**

   Circular product design, transparency, and traceability of products, components and materials are prerequisites for eliminating toxicants and recovering materials, rendering

more benefits for people with the same or lower amounts of materials *(well established)*. Mandatory requirements for product information systems to increase the transparency of chemical and material compositions and internationally harmonized circular product design and material processing standards are required {15.1.3, 15.2.1}.

2. **Creating fair and effective markets for circular goods and services across industries and global value chains**

Improving the transparency about materials and prices of circular goods and services is a key requirement to enabling traceability and achieving material circularity across value chains *(well established)*. Digital technologies such as product passports and blockchain protocols will play a crucial role in market transformation for circularity {15.2.1, 15.2.2}.

Including informal sector stakeholders, such as those working in waste management, repair and upcycling, is essential to ensuring a just transition to a circular economy (well established). This can be achieved through capacity-building, formal recognition and upholding the right to unionize, national labour law reforms and due diligence requirements, while ensuring socially just transitions and decent work, especially for women and Indigenous Peoples {15.2.2}.

Small and medium-sized enterprises will require capacity-building support and access to finance and technology (well established). This backing is vital to scale circular business models, create local employment opportunities, meet the requirements on traceability and reporting, and become integrated into international markets {15.2.1, 15.2.3, 15.2.4}.

Taxation reforms are needed, such as shifting taxes from recycled materials, secondary resources and labour to non-renewable resources and waste. This approach will capture the true value of natural resources and the costs of extraction, thereby reducing market failures and negative externalities *(established but incomplete)*. Measures to compensate low-income groups and to prevent rising energy and material costs must accompany these changes to ensure social equity {15.2.1}.

3. **Reform of the financial system to shift investments from linear extractive economic activities to circular and regenerative business models**

Building capacity within financial regulators, national institutions and across the finance sector to understand and evaluate the value proposition of circular and nature-positive business models is required *(well established)*. Enhanced capacity will enable financial institutions to develop and offer new financial products and revise risk-assessment tools to improve access to finance for circular businesses {15.2.3}.

Making financial information relating to the circularity of finance and investment portfolios publicly available will require the adoption of new metrics and disclosure of non-financial, nature-related reporting by companies and investors *(established but incomplete)*. This access can be achieved by international adoption and harmonization of sustainable finance taxonomies, green bonds and other methods by national financial regulators, central banks and the financial sector {15.2.3}.

4. **Enabling a transparent and fair global trade system for circular goods and services**

The global illegal waste trade is a multi-billion-dollar industry, with profits estimated between US$10 billion and US$12 billion annually *(well established)*. Expanding the existing mechanisms and international initiatives of law enforcement agencies to address the illegal waste trade and waste dumping practices, notably from developed to developing countries {15.2.4}.

Embedding circularity provisions in bilateral and regional trade agreements that provide preferential treatments and remove barriers to trade in circular goods and services is a key mechanism. Reducing tariffs on technologies essential for circular economy activities, such as advanced recycling, material recovery and pollution control, would be a critical step *(established but incomplete)* {15.2.4}.

Credit: ©UNEP

5. **Translating circularity aspirations into actionable societal goals**

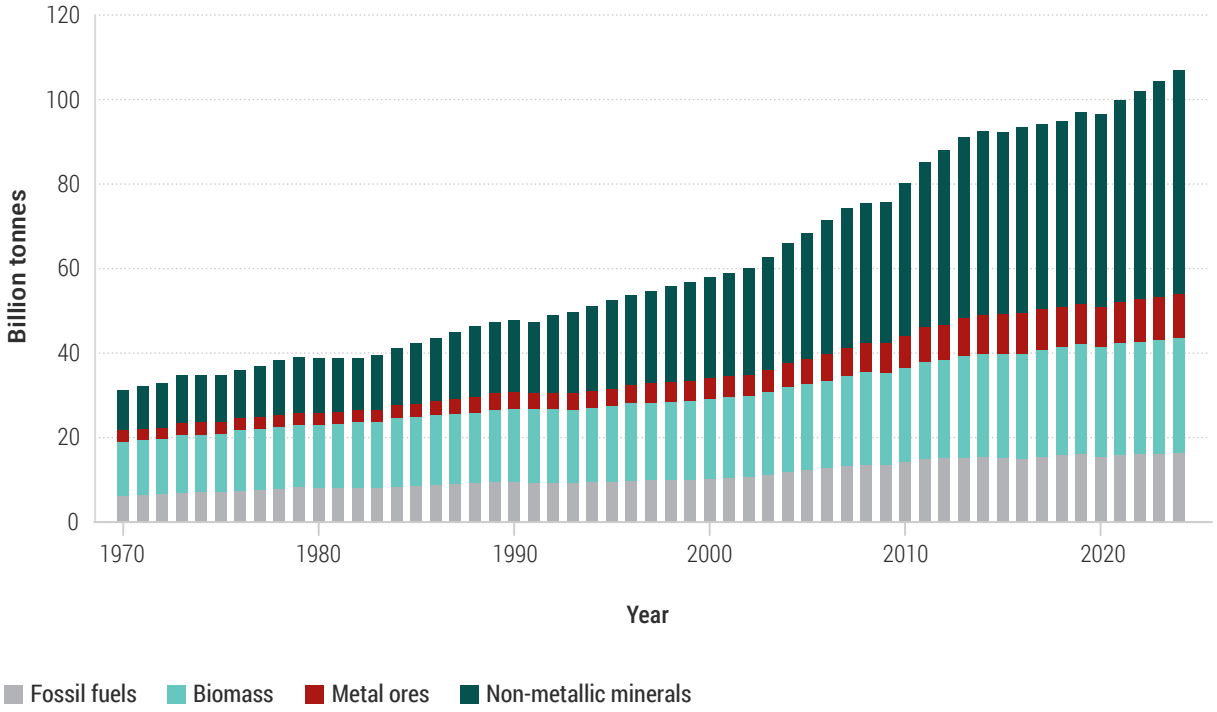
To make circular lifestyles convenient and practical, it is essential to implement enabling infrastructures and incentivize pro-circular behaviour *(established but incomplete)*. Easy-to-use schemes for product take-back, repair, reuse and renting will mainstream circular economy practices into society and promote new norms based on sufficiency. Standards for second-hand products and regulations protecting consumer rights will be needed to ensure societal acceptance, safety and the quality of circular goods and services *(well established)* {15.2.5}.

Implementing regulatory measures to phase out linear models while incentivizing circular choices will accelerate changes in consumption patterns *(well established)*. User charges for single-use products and items are a successful policy example of reducing wasteful practices and enabling the uptake of circular alternatives {15.2.5}.

The circular economy strongly intersects with the other solution pathways that are critical to addressing the global environmental crises *(established but incomplete)*. It aligns closely with the energy transition, particularly through the needed recovery and reuse of critical energy transition minerals. In the food system, circular practices help reduce food loss and waste while also supporting regenerative agricultural approaches. The circular bioeconomy is directly linked to environmental systems and is essential for the sustainable use of biological resources. Integrating circularity in the financial and economic systems involves tax reforms and efforts to align investment and finance with circular business models {15.4}.

15.1 Introduction

The circular economy is a systems approach to preserving resources that applies across all sectors – from the built environment and energy infrastructures to significant assets like ships and airplanes, as well as consumer products such as electronics and textiles. Integrating both technical and biological cycles not only minimizes waste and maximizes material value but also supports nature-positive outcomes through regeneration and sustainable resource management. It is an alternative to the current linear economic model of "take-make-dispose" that comes at the expense of nature and human health. This linear flow of materials – from extraction to disposal – drives demand for natural resources, increases emissions and significantly contributes to climate change and biodiversity loss. Since the 1970s, materials extraction has more than tripled, reaching 106.6 billion tons in 2024, following an annual average growth rate of 2.3 per cent **(Figure 15.1).**



According to the International Resource Panel's Global Resource Outlook, the extraction and processing of resources – fossil fuels, metals, non-metallic minerals and biomass – account for over 55 per cent of greenhouse gas (GHG) emissions and 40 per cent of health effects from particulate matter (United Nations Environment Programme [UNEP] 2024a). More than 90 per cent of terrestrial biodiversity loss is linked to resource extraction, with adverse effects on water and land use (UNEP 2019a; Jaureguiberry et al. 2022).

Collectively, the food, construction, energy, and textile sectors account for approximately 90 per cent of the pressure on biodiversity worldwide (European Environment Agency [EEA] 2023). There is a critical need to address the linear pressures driving biodiversity loss, as current conservation and regeneration efforts alone cannot solve this crisis (Intergovernmental Platform for Biodiversity and Ecosystem Services [IPBES] 2019). While the planet's environmental systems and regenerative capacity are severely under pressure, worldwide demand for resources is projected to more than double between 2011 and 2060 (Organisation for Economic Cooperation and Development [OECD] 2019).

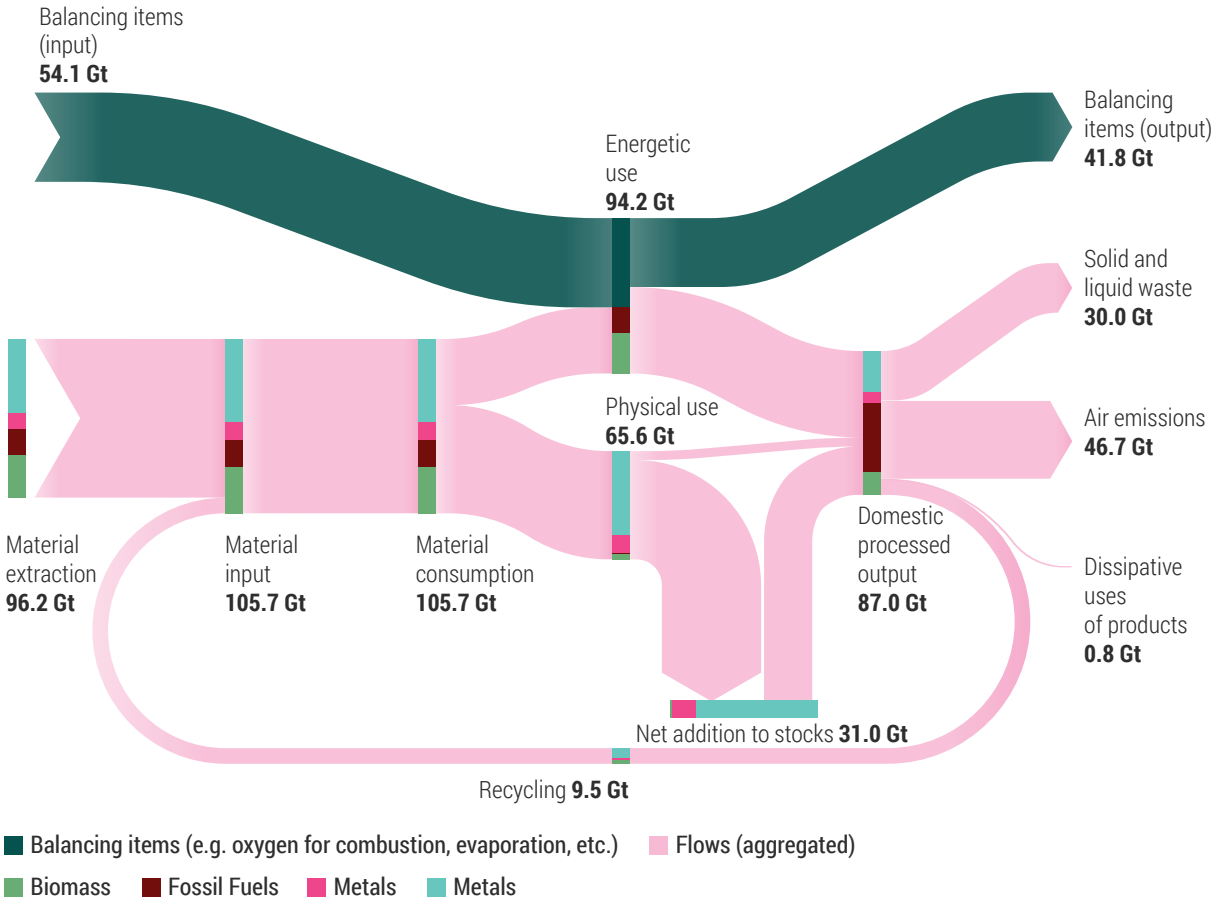
15.1.1 Linear economic flows cause excessive waste and pollution

Current production and consumption systems, with their linear patterns of material flows, create waste with volumes so high that the capacity to manage it safely has been lost. Reliably quantifying global waste is complicated by limited data availability for many waste types and differing reporting standards (Maalouf and Mavropoulos 2022a). In developing countries, particularly in rural areas, waste often remains uncollected (Kaza et al., 2018; UNEP, 2018a), and waste generation may be significantly underestimated. A broad grouping of urban wastes – municipal solid waste (MSW), commercial and industrial wastes, and construction and demolition wastes – was estimated at 7 billion to 10 billion tons per year (UNEP and International Solid Waste Association [ISWA] 2015). Total annual solid waste, estimated at 19.8 billion tons in 2017, is projected to reach 46 billion tons by 2050 (Maalouf and Mavropoulos 2022b), with MSW alone expected to rise by 81 per cent (2.1 billion to 3.8 billion) from 2023 to 2050 (Chen et al. 2020; UNEP 2024a). There are inconsistent estimates on whether waste generation growth will then continue and if a "waste peak" might be reached in the second half of this century (Hoornweg, Bhada-Tata and Kennedy 2013) or not (Chen et al. 2020).

Mismanaged waste is a significant contributor to GHG emissions and air pollution. About 15 per cent of global anthropogenic methane emissions come from decomposing organic material in landfill sites (Höglund-Isaksson et al. 2020). In 2023, open burning of MSW was responsible for 70 per cent of GHG emissions within the global MSW management sector (Gómez-Sanabria et al. 2022; Zaw et al. 2024; Wiedinmyer; UNEP 2024c;). The release of unintentional persistent organic pollutants harms ecosystems, leading to biodiversity loss (UNEP 2024c). The uncontrolled burning of plastics releases dangerous pollutants linked to a range of health issues, from cardiovascular and respiratory problems to neurological disorders (Pathak et al. 2023).

While global solid waste streams multiply, the world still lacks equitable waste management systems (ISWA 2021; UNEP 2024c). In 2020, the net costs and externalities of MSW management were US$361 billion and are expected to increase to US$640 billion by 2050 under business as usual without additional waste reduction and increased recycling rates (UNEP 2024c).

Mismanaged waste and pollution created by the linear economic system also have a human cost (UNEP 2024c). Pollution risk factors have risen by over 66



per cent since 2000 and in 2019 pollution contributed to approximately nine million premature deaths worldwide (Fuller et al. 2022). Annually, mismanaged waste disproportionately impacts low- and middle-income countries, contributing to an estimated 400,000 to one million deaths due to diseases like diarrhoea, malaria and cancer (Williams et al. 2019).

Especially global plastic pollution is worsening. An estimated 8000 Mt of plastic waste pollute the planet while production is projected to increase from 475 Mt in 2022 to 1200 Mt by 2060. Plastics cause disease and death and are responsible for health-related economic losses exceeding US$1.5 trillion annually (Landrigan et al. 2025) On a global level, a circular economy approach to address the global municipal waste crisis could generate a projected annual full net gain of US$108.5 billion by 2050 through waste avoidance, sustainable business practices, and fully circular waste management (UNEP 2024c).

15.1.2 Goals of the transformation from a linear to a circular economy

The Global Resources Outlook quantified that in 2019, secondary resources from recycling and material recovery contributed 9 per cent to the 105.7 billion tons of materials taken in by the global economy, while most material intake was extracted or harvested primary resources **(Figure 15.2)**. Of the 60 per cent used as structural and technical materials, half was incorporated into durable assets such as buildings, transportation and communication infrastructure, equipment and consumer products. This use was accompanied by significant quantities of solid and liquid waste, amounting to 30 billion tons, and gaseous emissions. Mainly non-metallic minerals and metals contributed to a net addition of 31 billion tons to material stocks as accumulated durable assets (UNEP 2024a). This trend shows a growing resource

Figure 15.2: Global material flows, waste and emissions

Note: The balancing items amount to 54.1 billion tonnes on the input side and 41.8 billion tonnes on the output side. These figures include factors such as oxygen used in combustion and evaporation. Such components are necessary to ensure that the system's inputs and outputs are properly balanced.

Source: Global Material Flows Database (UNEP 2023a)

demand and a significant future anthropogenic resource potential.

Achieving a circular economy is not a goal in itself but a means to address the global environmental crises and attain environmental sustainability, economic prosperity, equitable distribution of resources, human well-being and other essential objectives of the Sustainable Development Goals (Schroeder, Anggraeni and Weber 2019; Ferraz and Pyka 2023).

Based on the assessment of the literature in Chapters 2–6, the following four high-level goals are defined for the circular economy transformation:

Goal 1: Achieve absolute reductions in extraction and consumption of natural resources within recognized planetary boundaries and attain near-zero waste and pollution across the life cycle, from materials extraction to end of life. This goal involves redesigning products, processes and business models to address legacy waste issues and eliminate the generation of waste, wastewater and pollution, thereby contributing to a cleaner and healthier environment through an inclusive approach.

Goal 2: Ensure net-positive contributions to biodiversity, ecosystem health and soils through materials recovery, nutrient cycling, restoration and regeneration practices, recognizing and respecting the vital roles of Indigenous Knowledge and Local Knowledge, and the practices and innovations of Indigenous Peoples, their customary and biocultural systems, and their rights over lands, waters and territories.

Goal 3: Achieve climate stabilization through industrial decarbonization and near-zero life-cycle emissions from materials extraction, processing, use and end of life. This goal encompasses improving energy efficiency and transitioning to renewable energy sources across all sectors. Reduce the effects of climate change on vulnerable populations and communities, including Indigenous Peoples, and support climate adaptation and resilience through the application of circular economy principles, innovations and technologies (Wang et al. 2022).

Goal 4: Promote equitable socioeconomic development and sustainable lifestyles by creating safe and decent jobs, preventing adverse health effects and costs to society from mismanaged waste and pollution, while building resilient supply chains and ensuring that the transformation to a circular economy benefits all members of society and contributes to global efforts to eradicate poverty and promote social inclusion.

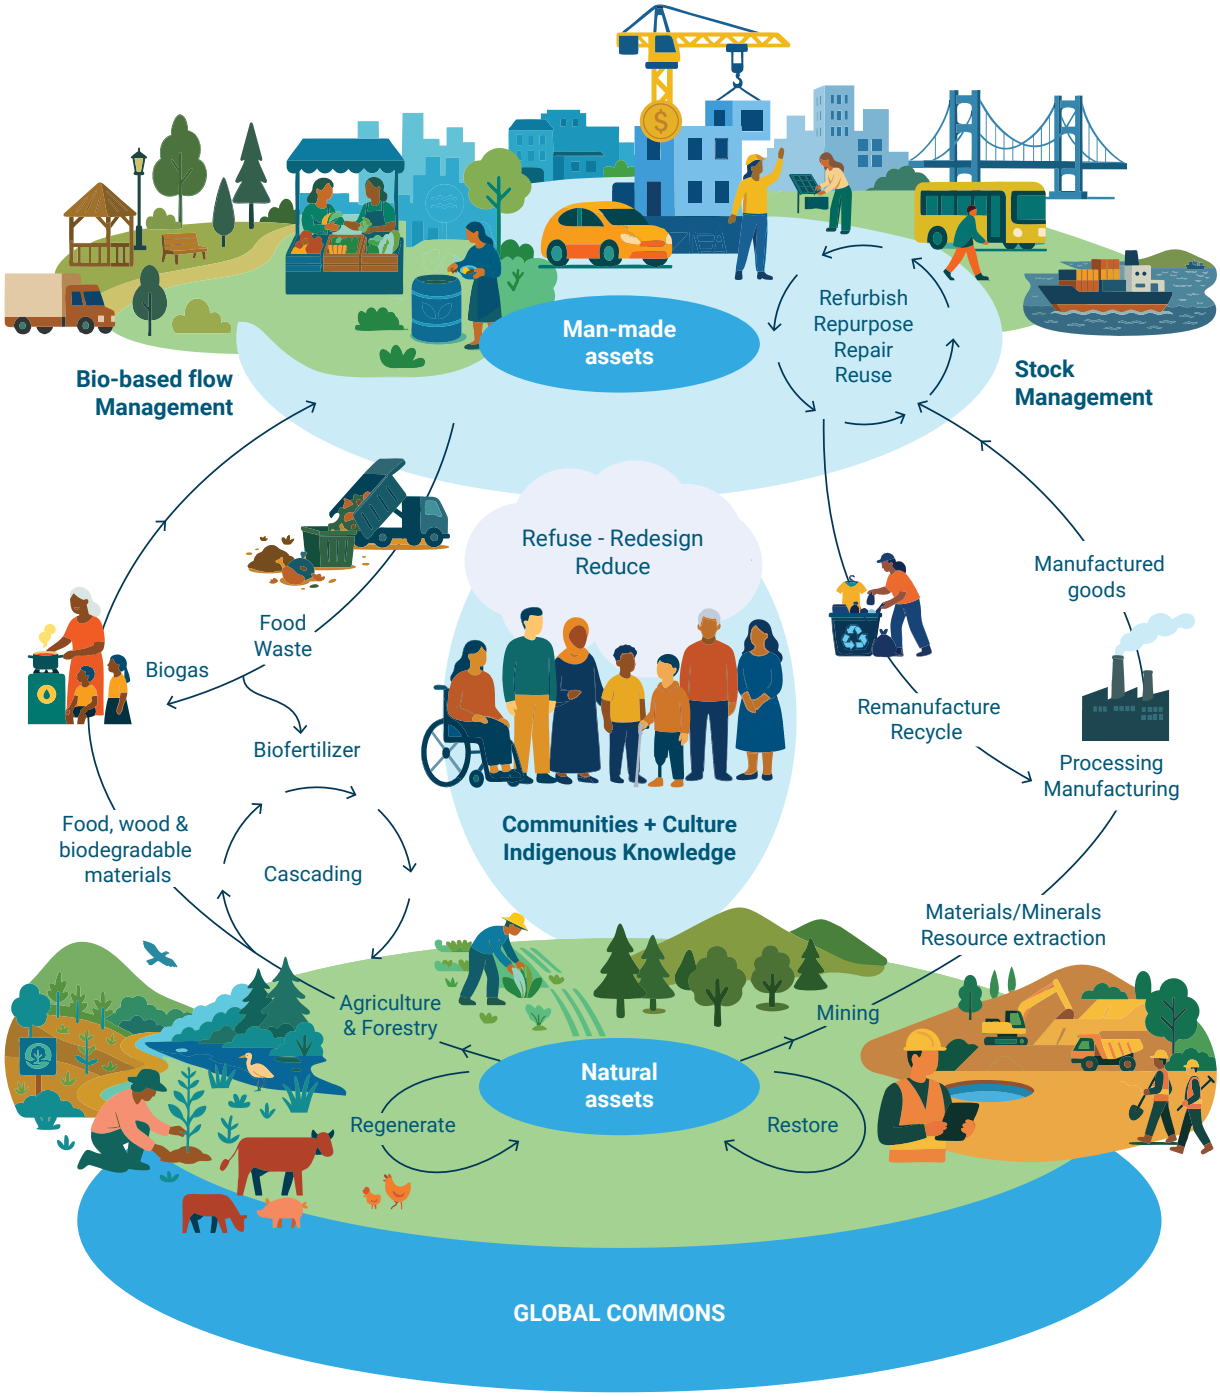
The solution pathways proposed in Section 15.2 follow the 7-step evaluation methodology described in Chapter 13. To achieve the four goals just described, combinations of levers and solutions are presented in the five solution pathways in Section 15.2. The actions proposed in the pathways match the three phases of the X-curve: activation, acceleration, and completion of the transformation (Chapter 13). The proposed actions explicitly include measures to phase out or remove elements of the linear economic system. Each solution pathway evaluates and prioritizes solutions according to immediate actions and longer-term strategies. Key actors and their interactions on international, national and local levels are identified to realize the potential of the circular economy.

15.1.3 Potential of the circular economy to address the global environmental crises

The circular economy concept emulates the cyclical processes in nature by aiming to preserve material value (Stahel 2019; Patwa et al. 2021). The circular economy, as a life-cycle approach, significantly reduces both unsustainable consumption of primary natural resources and waste and pollution. It is, in many ways, a heuristic for transforming the linear economy into one that is "… regenerative and restorative by intention and design…" (Ellen MacArthur Foundation 2015).

There are variations in meaning associated with restoration and regeneration in the circular economy literature. Restorative practices emphasize a continuous loop of use, reuse and repair, while regenerative practices involve cycles that sustain ecosystem functionality and enhance the self-renewal capacity of biological systems (Morseletto 2020). The circular economy model employs systems thinking, where effective strategies for sustainable resource usage consider how the entire system functions and how its elements interact with one another. This model acknowledges that the economic process also engages with values and culture, immaterial and financial assets, and institutional frameworks (Morseletto 2020; Balanay and Halog 2021; Iacovidou, Hahladakis and Purnell 2021). Integrating regenerative principles into systems thinking promotes ecological restoration and biodiversity enhancement, ensuring that economic activities contribute to the self-renewing capacity of ecosystems. This approach aligns with global

Credit: antonpetrus/Envato



frameworks such as the Kunming-Montreal Global Biodiversity Framework and the Nature Positive Initiative, an international civil society-led framework (Nature Positive Initiative 2025) that stress the importance of a measurable recovery of nature by 2030 and thriving ecosystems by 2050. Circularity is an integral part of the worldview practised by Indigenous Peoples around the world, with value systems, innovations and practical ancestral pathways of living within natural cycles, as well as customary and biocultural initiatives (Rai 2023).

At its simplest level, the circular economy primarily applies to products, components and materials and is commonly associated with "closing the loop" through energy and material efficiency. A more sophisticated approach aims at transforming systems such as mobility, the built environment, and food and energy systems through strategies and principles that slow, close, and narrow resource loops (Bocken et al. 2016). These strategies contribute to a circular economy by prolonging product use (slowing), enhancing recycling and reuse (closing), and reducing resource input per unit of service (narrowing) (Stahel and Clift 2016). It is, therefore, possible to achieve near-zero waste systems in which resource inputs and waste generation are reduced to the lowest practical level, ideally diverting at least 90 per cent of all discarded materials from landfill and incineration through redesign, reuse, recycling and recovery.

Circularity can maintain and create value at many levels – from improving a single product's life cycle to reconnecting human activities with natural systems. A circular economy sustains both man-made assets and natural capital by applying the 9R principles at various levels and scales, ensuring the regeneration, repair, reuse, and recycling of resources. By integrating these principles into production and consumption systems, it fosters resilient communities and healthy ecosystems. Central to this approach is the well-being of people, as the circular economy provides equitable provisioning systems that support social and economic needs. (**Figure 15.3**).

The circular economy encourages a shift in focus from simply generating income and using up resources to maintaining and regenerating the natural and social systems – also considered as capital – that support human lives. Instead of turning natural and social capital into financial profit, the circular approach prioritizes preserving and improving these essential resources. Some experts view the circular economy as a new perspective on how economies function, drawing inspiration from complex, self-regulating systems found in nature (Von Bertalanffy, 1968), particularly living systems and their principles (Capra and Jakobsen, 2017). This means creating an economy where waste becomes a resource and materials flow in loops rather than being extracted and used up. These insights from complex adaptive systems are also becoming increasingly relevant for industrial supply chain networks (Braz and Marotti de Mello 2022), circular manufacturing systems (Roci et al. 2022), and the organizational management of circular business models (De Angelis 2022).

Figure 15.3: **Connecting natural and man-made assets through regenerative and circular flows**

15.1.4 From concept to policy design and implementation

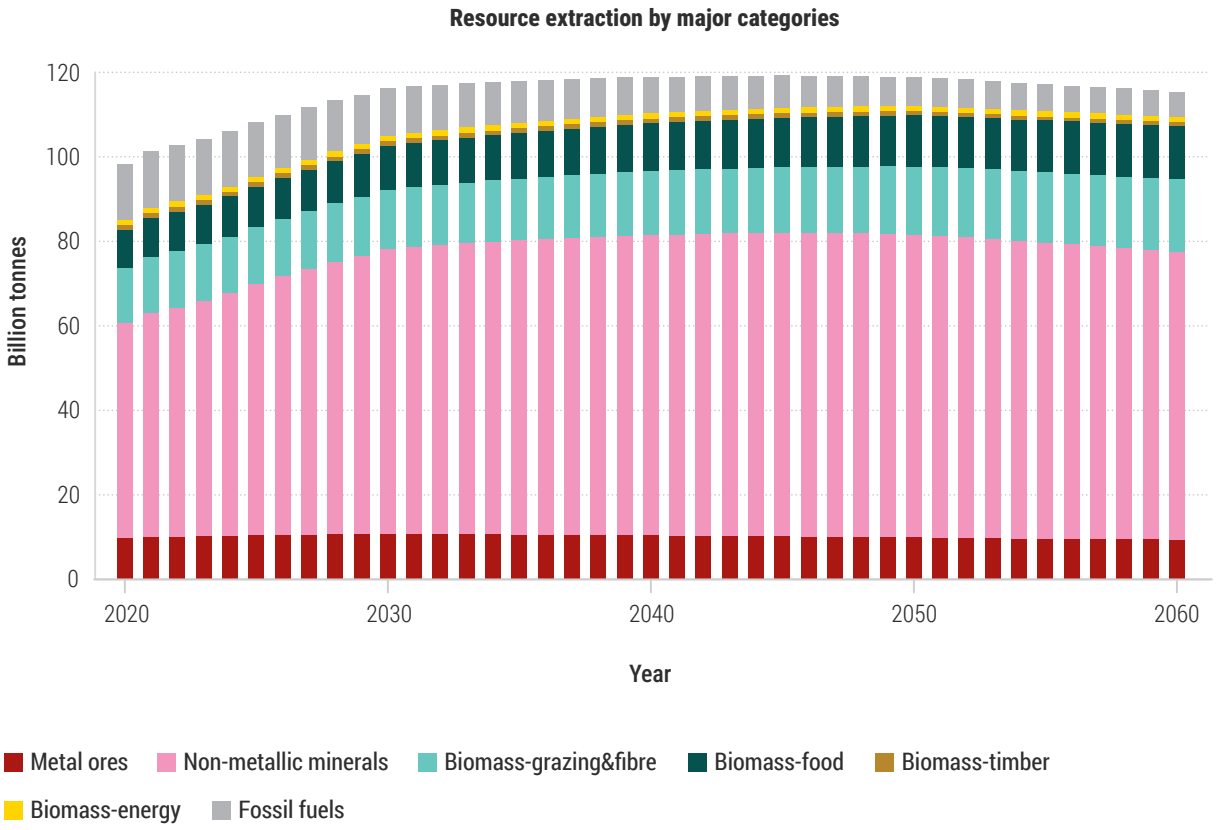
A global policy stocktake conducted by the United Nations Industrial Development Organization and Chatham House identified a total of 75 national circular economy road maps launched by governments worldwide – up from only four in 2016. These road maps include a collective commitment from governments to introduce nearly 3,000 circular economy policies spanning 17 sectors, making it one of the fastest-growing environmental policy categories worldwide over the next decade (Barrie et al. 2024). Common definitions, metrics and frameworks are essential for effective circular policy design and road map implementation because they enable alignment across stakeholders, ensure comparability of progress, and provide a clear basis for setting targets, measuring results and coordinating actions at local, national and international levels.

While there are numerous definitions of the circular economy in the scientific literature (Kirchherr et al. 2023),

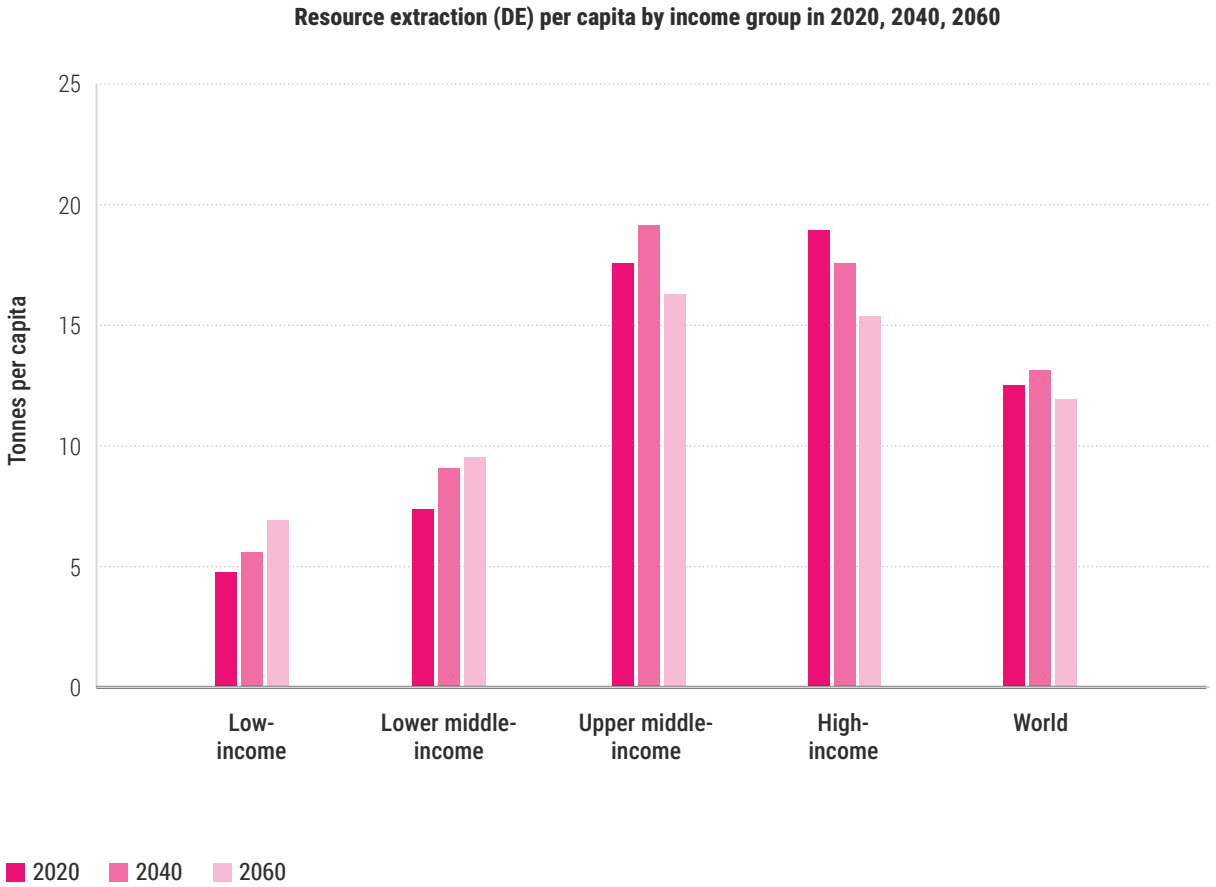
the United Nations Economic Commission for Europe (UNECE) along with the OECD developed a set of common guidelines within a framework of concepts, terms and definitions. The headline definition of the circular economy combines the common elements of existing definitions: "maintaining the value of materials in the economy for as long as possible while ensuring a positive outcome to society, and preserving natural capital (natural resources, environmental quality) and human health." (UNECE 2024). The ISO 59000 family of standards, specifically designed to foster a shift towards a circular economy, is particularly relevant for policy implementation and for the private sector reconfiguring business models. It defines the circular economy as an "economic system that uses a systemic approach to maintain a circular flow of resources (concerning both stocks and flows), by recovering, retaining or adding to their value, while contributing to sustainable development" (International Organization for Standardization [ISO] 2024).

The 9R model has emerged as a commonly used framework in policymaking. The model consists of nine practices or strategies that help to maximize the value of materials and reduce waste throughout their life cycle (Potting et al. 2017). It provides a structured hierarchy of circular strategies for policymakers that helps prioritize actions, design effective interventions and assess the circularity potential of policies and practices. The framework continues to evolve, with new R-strategies such as regenerate, rethink, and recover being proposed, which reflect the increasing sophistication of the circular economy and its expanding scope.

15.1.5 From resource extraction to maintenance of material stocks – International Resource Panel and GEO-7 modelling and scenario results



Economic growth drives not only resource depletion and waste generation but also net additions to stocks of materials (Robinson 2022). Significant quantities of minerals and aggregates and lesser amounts of steel, aluminium and plastics enter stock in the form of infrastructure and the built environment and are locked away for upward of 30 years (Plank et al. 2022). An increased focus on long-term management of materials is needed in national economies around the world. Stock saturation for materials such as steel and concrete is anticipated for 2035 in some countries (Wiedenhofer et al. 2021). Reducing expected future demand increases from material stock will require circular approaches, including more intensive utilization of existing stocks, longer service lifetimes, refurbishment, and more efficient and circular building design (Bragança et al. 2025).



According to modelling by GEO-7 contributors and the International Resource Panel, global material demand can be cut by 26 per cent by transitioning to a circular economy. Key resource categories, including minerals, metals, fossil fuels and biomass, are estimated to peak below 120 billion tons per year by mid-century, compared to a historical trend scenario where global resource extraction would exceed 160 billion tons per year before stabilizing (UNEP, 2024a). The achieved reduction in material demand translates into savings at the global level, down to 13 tons per capita by 2050, from 16 tons per capita under current trends (Chapter 10, Section 10.3.3). This circularity scenario primarily considers optimized recycling rates, especially for non-metallic minerals and metals. Further essential reductions in resource extraction can be achieved by adopting circular practices, such as reuse, repair, remanufacturing and refurbishment, to preserve material stocks and facilitate the adoption of sustainable lifestyles. Achieving this objective also requires embedding circular design principles and transforming systems in key areas, such as mobility, energy and the built environment, to reduce material demand and extend the life of products and infrastructure.

Several key interventions are necessary to achieve global economic circularity for these major resource categories. One crucial step would be the establishment of a global target for resource use alongside clearly defined global and national resource-use pathways. For example, Germany has set an absolute material footprint reduction target, aiming for per capita material consumption of six to eight tons by 2050, as outlined in its 2024 national circular economy road map (Breschi 2024). Similarly, in the ongoing United Nations process of the Intergovernmental Negotiating Committee on Plastic Pollution, setting a global production target for primary plastics will help drive coordinated action on resource efficiency and plastic waste minimization (Pottinger et al. 2024).

Robust monitoring frameworks and data are also essential in tracking global progress. The European Union's circular economy indicator framework can serve as a valuable reference for developing clear, standardized indicators at both national and international levels. Institutionalizing resource use within sustainability agendas and environmental agreements – both globally and nationally – would also ensure long-term policy commitment. To support this, the establishment of an international resource agency could play a pivotal role in coordinating national

Figure 15.4: Resource extraction globally by major categories and per capita by income group

policy actions, facilitating data and information exchange on resource utilization, building capacity for monitoring progress and ensuring alignment between national and international targets on resource efficiency, waste reduction and material circularity (UNEP 2024c; Barrie et al. 2024).

15.1.6 A spotlight on the circular economy potentials for key sectors and value chains with high environmental and resource footprints

In the transformation to a circular economy, key industrial sectors and global value chains with high environmental and resource footprints merit specific attention, both in terms of their material input and economic opportunities. In the United States of America alone, moving to a circular economy in three industries – the built environment, electric vehicles and battery manufacturing – could cut raw material inputs and unlock US$883 billion to US$1.5 trillion in new revenue and economic value, which corresponds to 4-7 per cent of US gross domestic product (GDP) (Ellen MacArthur Foundation 2024). For the African continent, key sectors of the food system – plastics and packaging, the built environment, electronics, and fashion and textiles – could create new employment opportunities, eliminate waste and emissions, and reduce resource use under a circular economy (Alliance, 2021). For the Asia and the Pacific region, the circular economy could boost GDP by US$340 billion – a 1.1 per cent net growth – and reduce net emissions by 7.2 per cent compared to business as usual (PricewaterhouseCoopers [PWC] 2024).

In hard-to-abate industry sectors such as steel, cement and chemicals, circular strategies including material reuse, remanufacturing, design for longevity, and product-as-a-service models will be essential for tackling Scope 3 emissions, which reflect totals through a value chain. However, current accounting tools, such as the GHG Protocol, lack sufficient guidance on how to capture the emissions benefits of circular practices for Scope 3 accounting (Greenhouse Gas Protocol, 2013). Updating these methodologies to reflect circular strategies will enable more accurate carbon accounting and incentivize system-wide decarbonization.

The circular economy is also relevant for global industries like shipping, where ship-breaking presents major environmental and labour rights challenges but also opportunities for responsible material recovery and reuse, for example, secondary steel. Circular economy principles can extend ship lifespans by improving dismantling processes and maximizing resource efficiency (Rahman and Kim 2020). At the same time, circularity is gaining attention in emerging global issues such as space debris. The European Space Agency has proposed developing a circular space economy by 2050, aiming to design spacecraft, satellites and missions with reuse, repair and end-of-life recovery in mind – highlighting the growing importance of circular principles applied to activities in Earth and lunar orbits (Turner 2024).

The following paragraphs offer a brief overview of key challenges and the potential for circular-economy solutions in selected priority sectors highlighted in national circular economy road maps and targeted by government strategies (Barrie et al. 2024).

Built environment and construction:
While the construction sector's particularly high material consumption is responsible for 40 per cent of GHG emissions, construction activities convert resources into beneficial structures for long-term use; (International Resource Panel 2020; UNEP 2022; International Finance Corporations 2023). At the same time, construction and demolition waste often dominates solid waste generation, contributing about 10 billion tons per year globally (Wu et al. 2019). This mixture of inert, non-inert non-hazardous, and hazardous waste varies greatly in composition between regions (Menegaki and Damigos 2018). Circular economy practices in some European Union Member States already achieve recycling construction and demolition waste rates of more than 90 per cent, while globally one third are sent to landfills (Chen et al. 2022). In the building sector, circular-economy actions such as retrofitting, refurbishment and recycling can reduce a building's materials-related total GHG emissions by up to 61 per cent (Ramboll, Fraunhofer and Institute 2020). Recycling concrete and cement from demolition rubble is an emerging technological solution that can help "build cities from cities" with reduced material footprints (Gebremariam et al. 2020; Dunant et al. 2024). Recycling cement paste from concrete can potentially reduce emissions from cement production by 15 per cent, equivalent to 0.8 per cent of 2020's global anthropogenic GHG emissions (Driver et al. 2024). Beyond recycling, circular solutions such as floor space reduction and lightweight building design can reduce cumulative GHG emissions by up to 44 per cent for the period 2020–2050 (Pauliuk et al. 2024).

Policies such as setting mandatory demolition recycling rates or new construction minimums for recycled materials at 90 and 15 per cent, respectively, have proven successful in several European countries (Interreg Europe 2024).

Furthermore, the built environment can go beyond minimizing harm and adopt regenerative, nature-positive practices (World Business Council for Sustainable Development 2023). Regenerative design can create buildings that enhance natural ecosystems through appropriate tools and technologies. This shift can mark an evolution from green buildings to regenerative and circular buildings, which actively contributes to environmental regeneration (Stracqualursi and Andreucci 2023). Switching from carbon-intensive materials to sustainably harvested renewable materials such as timber and bamboo and utilizing Indigenous Knowledge and traditional materials can support resilient local supply chains, job creation, preservation of local culture, and enhancement of regenerative local natural systems (Churkina, Organschi and Reyer 2020).

Plastics:

These are ubiquitous in modern societies, with 98 per cent made of synthetic, fossil-fuel-derived polymers (Schirmeister and Mülhaupt 2022). According to the OECD's Global Plastics Outlook, current plastic waste leakage into the environment amounts to 22 million tons per year and is expected to double to 44 million tons by 2060 if no policy action is taken (OECD 2022a). A circular economy has the potential to reduce up to 80 per cent of plastic pollution, thereby saving external costs estimated at around $18 trillion by 2040. In the absence of policy action, the externalized costs to the environment and society are projected to be significantly higher. (UNEP 2023a; Landrigan et al. 2025). The growing plastic pollution crisis endangers food security, human health, and marine ecosystems in Indigenous communities across the Arctic (WWF 2024), while in the Asia and the Pacific region, it contaminates waters, food sources such as fish and shellfish, poses serious health risks and disrupts cultural practices – further threatening Indigenous Peoples' traditional way of life.

In 2015, plastics accounted for 4.5 per cent or 1.7 billion tons of CO_2-equivalent (CO_2e) of global GHG emissions and could grow to 6.5 billion tons CO_2e by 2050 under the current trajectory (Zheng and Suh 2019; Stegmann et al. 2022). Circularity can help address these issues as it can directly reduce GHG emissions from plastics. For example, black carbon from the open burning of plastics and other waste could be eliminated by 2050 through circular waste management approaches (Reyna-Bensusan et al. 2019; Gómez-Sanabria et al. 2022).

Plastic recycling rates are increasing globally yet are still very low. The share of end-of-life plastics that was recycled in India, China, and Europe in 2019 was 12–13 per cent, in Sub-Saharan Africa 5.7 per cent, while the US managed to reach only a 4.5 per cent recycling rate (OECD 2022b). The single-use feature of a large proportion of plastics is the most problematic aspect, together with the propensity of plastics to break down into micro- and nanoplastics. These tiny plastic bits have become ubiquitous in the environment and even human bodies, and their ability to adsorb, as well as release, hazardous chemicals is an added danger. To enable a safe and non-toxic circular plastic economy, there is a need for improved transparency and harmonized measures in addressing chemicals of concern in plastic products. Plastics and polymers that hinder circularity, such as flexible plastics, thermosets and polyvinyl chloride, are especially problematic and need to be phased out (Tan, Jia and Ramakrishna 2023; Lisiecki et al. 2023).

There are economic barriers to circularity, such as primary plastics being persistently cheaper than recycled ones, and social practices that favour the convenience of single-use versus multiple-use products (UNEP 2023b). A combination of addressing upstream production, curbing plastics demand and designing for circularity, as well as downstream solutions such as recycling and waste management, will be the most cost-effective pathway to eliminate plastic pollution by 2040 (OECD 2024b). The cross-contamination of recycled materials with chemicals must also be addressed (Aurisano, Weber and Fantke 2021; UNEP 2023c). More than 4,200 chemicals used or found in plastics are of environmental or human health concern due to toxic, persistent, bioaccumulative or mobile characteristics. Furthermore, two-thirds of the over 16,000 plastic-related chemicals lack hazard assessments, and only 1 per cent of those assessed are considered non-hazardous (Wagner et al. 2024). Addressing these chemicals of concern is key to creating a circular plastics economy. The adoption of the Global Framework on Chemicals is a step towards supporting developing countries in the safe and sustainable management of chemicals and waste. The framework builds on the Strategic Approach to International Chemicals Management and guides governments and stakeholders in jointly addressing the life cycle of chemicals, including products and waste.

Textiles:

The fashion and textiles industry has significant environmental repercussions throughout its global value-chain operations, from waste generation to

resource consumption and carbon footprint. Textiles' global value chain accounts for an estimated 2–8 per cent of GHG emissions, consumes an estimated 215 trillion litres of water and contributes 9 per cent of annual microplastic pollution to the oceans (UNEP 2023d). The Global Chemicals Outlook identified the textile sector as a significant contributor of chemicals of concern and persistent organic pollutants; circular solutions would involve reducing the use of harmful chemicals and promoting more environmentally sound alternatives (UNEP 2019).

Less than 1 per cent of the material used to produce clothing is recycled into new clothing, and most is either incinerated or sent to landfills (Ellen MacArthur Foundation 2017). Between 2000 and 2015, clothing production doubled, while the number of times that an item is used before it is discarded decreased by an estimated 36 per cent, leading to an estimated equivalent of a garbage truck full of clothing being thrown away every second (Ellen MacArthur Foundation 2017). Shifting consumption patterns, scaling circular business models and improving clothing utility and durability, improving production practices, addressing low garment quality, , and investing in renewable energy infrastructure can move the sector towards circularity (UNEP 2023a). Second-hand clothing markets and the recycling of fabrics and fibres are among the circular economy solutions for the textile and garment sector (Baloyi et al., 2023).

Electronics, digital technologies and data centres: Information and communication technology industries are experiencing rapid growth that will accelerate in the coming decades. Approximately 62 million tons of e-waste was generated globally in 2022, growing five times faster than documented e-waste recycling (United Nations Institute for Training and Research 2024). The accelerating development of artificial intelligence and data centres contributes additional e-waste, potentially reaching a total accumulation of between 1.2 million and 5.0 million tons during 2020–2030 (Wang et al. 2024).

E-waste data has increased annually since systematic records began in 2014. China and the United States of America are the largest generators of e-waste, and nearly 10 per cent, or 5.1 million tons, of global e-waste crossed country borders in 2019. Around 35 per cent of the transboundary movement was shipped in a controlled manner, while nearly two-thirds or 3.3 million tons, was uncontrolled or shipped illegally (United Nations Institute for Training and Research 2022). At the global level, only 22.3 per cent was recycled in a formal manner, and the majority was stored or disposed of informally (Zeng and Li 2021; United Nations Institute for Training and Research 2024). At the same time, e-waste recycling offers significant economic opportunities, with the global market potential expected to reach US$65.8 billion by 2026 (Seif, Salem and Allam 2024).

New digital technologies like artificial intelligence and machine learning can enable material circularity and circular business models for material tracking and resource optimization in the circular economy, but will also result in additional e-waste generation and resource demands. Dozens of material types, including rare earth metals and other critical energy transition materials, are found in the servers, storage and networking equipment of data centres. Embedding circularity principles in their design and operation will help reduce resource demands in future (Hoosain et al. 2023).

Critical energy transition minerals:
The adoption of clean energy technologies implies an increasing demand for critical energy transition minerals such as aluminium, copper, cobalt, lithium, nickel, and rare earth elements such as neodymium and coltan. Demand is projected to almost triple by 2030 and grow to over 3.5 times the current levels by 2050, reaching nearly 40 million tons (International Energy Agency [IEA] 2024). Mining in many regions will escalate, with adverse effects on biodiversity and Indigenous Peoples' rights, as well as increased water pollution and land degradation (UNECE 2023a). Of the 5,097 existing energy transition mineral projects globally, an estimated 54 per cent are located on or near Indigenous Peoples' lands, waters and territories and will require free, prior and informed consent (Owen et al. 2023), full and effective participation, and fair and equitable benefit-sharing with Indigenous Peoples (Owen et al. 2023). Circular solutions such as lifetime extension, sharing models, materials recovery and recycling can help to reduce overall demand for primary mined materials, as well as alleviate political tensions about securing access (Geng, Sarkis and Bleischwitz 2023). Models show that new technological solutions and circular economy approaches, such as lifetime extension through repair and refurbishment of renewable energy equipment, and the recycling of materials, can reduce the demand for the mining of critical energy transition minerals by up to 58 per cent from 2022 to 2050 (Simas, Aponte and Wiebe 2022). For materials like cobalt, which currently has a global recycling rate of only about 5 per cent, if recycling rates were to increase to 90 per cent by 2050, this could cover

20 per cent of global demand by 2040 and 30 per cent by 2050 (Systemiq 2022; University of Cambridge Institute for Sustainability Leadership and The Wuppertal Institute 2023). Advanced metal and mineral recycling processes for low-carbon energy and storage technologies already exist but need to be scaled up (Zante et al. 2024). New technological, economic and logistical approaches are needed, especially for hard-to-recycle materials such as rare earth metals, which currently have recycling rates as low as 1 per cent (Wayman 2023).

A comprehensive strategy that integrates investment, innovation, recycling, rigorous sustainability standards, and well-designed safety nets must be developed (IEA 2023). The urban mining of scrap and e-waste can deliver enhanced resource sustainability and improved environmental protection while developing a circular economy for critical minerals essential for the energy transition. Since urban mines increasingly serve as a key material source for a circular economy, it is essential to include their prospecting into national data-collection activities in all countries. Furthermore, identifying, accounting for and assuming the cost of externalities in the extraction of energy transition minerals will help make urban mining and circularity more financially viable.

Ultimately, producer countries must retain and value their local resources. The Nairobi Declaration and Call to Action, signed by African leaders in 2023, advocates for the advancement of green industrialization across the continent. By leveraging Africa's significant renewable energy potential, the establishment of energy-intensive processing industries would require fewer resources and raw materials than in other regions (African Union 2023).

15.2 Potential solutions to achieve transformative change – immediate policy actions and strategic long-term planning

To achieve the shift to a circular economy, policymakers need to engage in strategic long-term planning over the next two to three decades. This section highlights possible actions that can be implemented immediately, as well as longer-term planning and policy implementation. The solutions summarized in **Figure 15.5** and **Figure 15.6** are not a one-to-one match between a pathway and the high-level goals defined in Section 15.1.2 for the circular economy transformation. Pathways will contribute to multiple goals through a combination of actions and solutions. The five levers described in Chapter 12 - economics and finance, individual and collective action, knowledge and innovation, governance, capabilities– are an integral part of the solutions, reflecting the systemic approach of the circular economy. Each pathway presents a collection of actions, their sequencing, and the appropriate actors for their implementation.

15.2.1 Solution pathway 1: Designing out waste/designing in circularity into the full life cycle of products

Circular design is often associated with the creation of products, components and materials, but it also encompasses business models and systems design (Moreno et al. 2016; Charter 2019). Systems thinking prioritizes connections and processes, not isolated parts. A circular economy is not only about material or energy recovery but improves the entire economic model. It is based on adopting a life-cycle perspective as well as factoring in the interaction between any process and the environment and the economy in which it is embedded (Ghisellini, Cialani and Ulgiati 2016). A truly cyclical system designs out waste. The value embedded in materials is preserved through their use in high-value applications (Korhonen, Honkasalo and Seppälä 2018), while any emissions are productively taken up by another process.

A systemic approach that designs circularity into the product's entire life cycle slows resource flows through durability and life extension – repair, refurbishment, remanufacturing – while closing resource cycles by transforming waste materials into value (Geissdoerfer et al. 2018; McDonough and Braungart 2002). Life-cycle analysis is an essential tool in assessing the effects of products, but small and medium-sized enterprise suppliers in developing countries often lack the resources for such studies. Circularity-oriented product design, circular business models, and supporting governance throughout the entire value chain, while also considering potential trade-offs and rebound effects, are prerequisites for integrating circularity into the system (Zink and Geyer 2017). For example, shifting business models from "scale and sale" to alternatives that focus on increased product utilization or access on demand is facilitated by mandating extended producer ownership or liability (Stahel 2019).

The following set of actions will be required to implement this solution pathway.

Figure 15.5: Summary of the proposed five solution pathways and actions for transformative change towards a circular economy from now until 2050

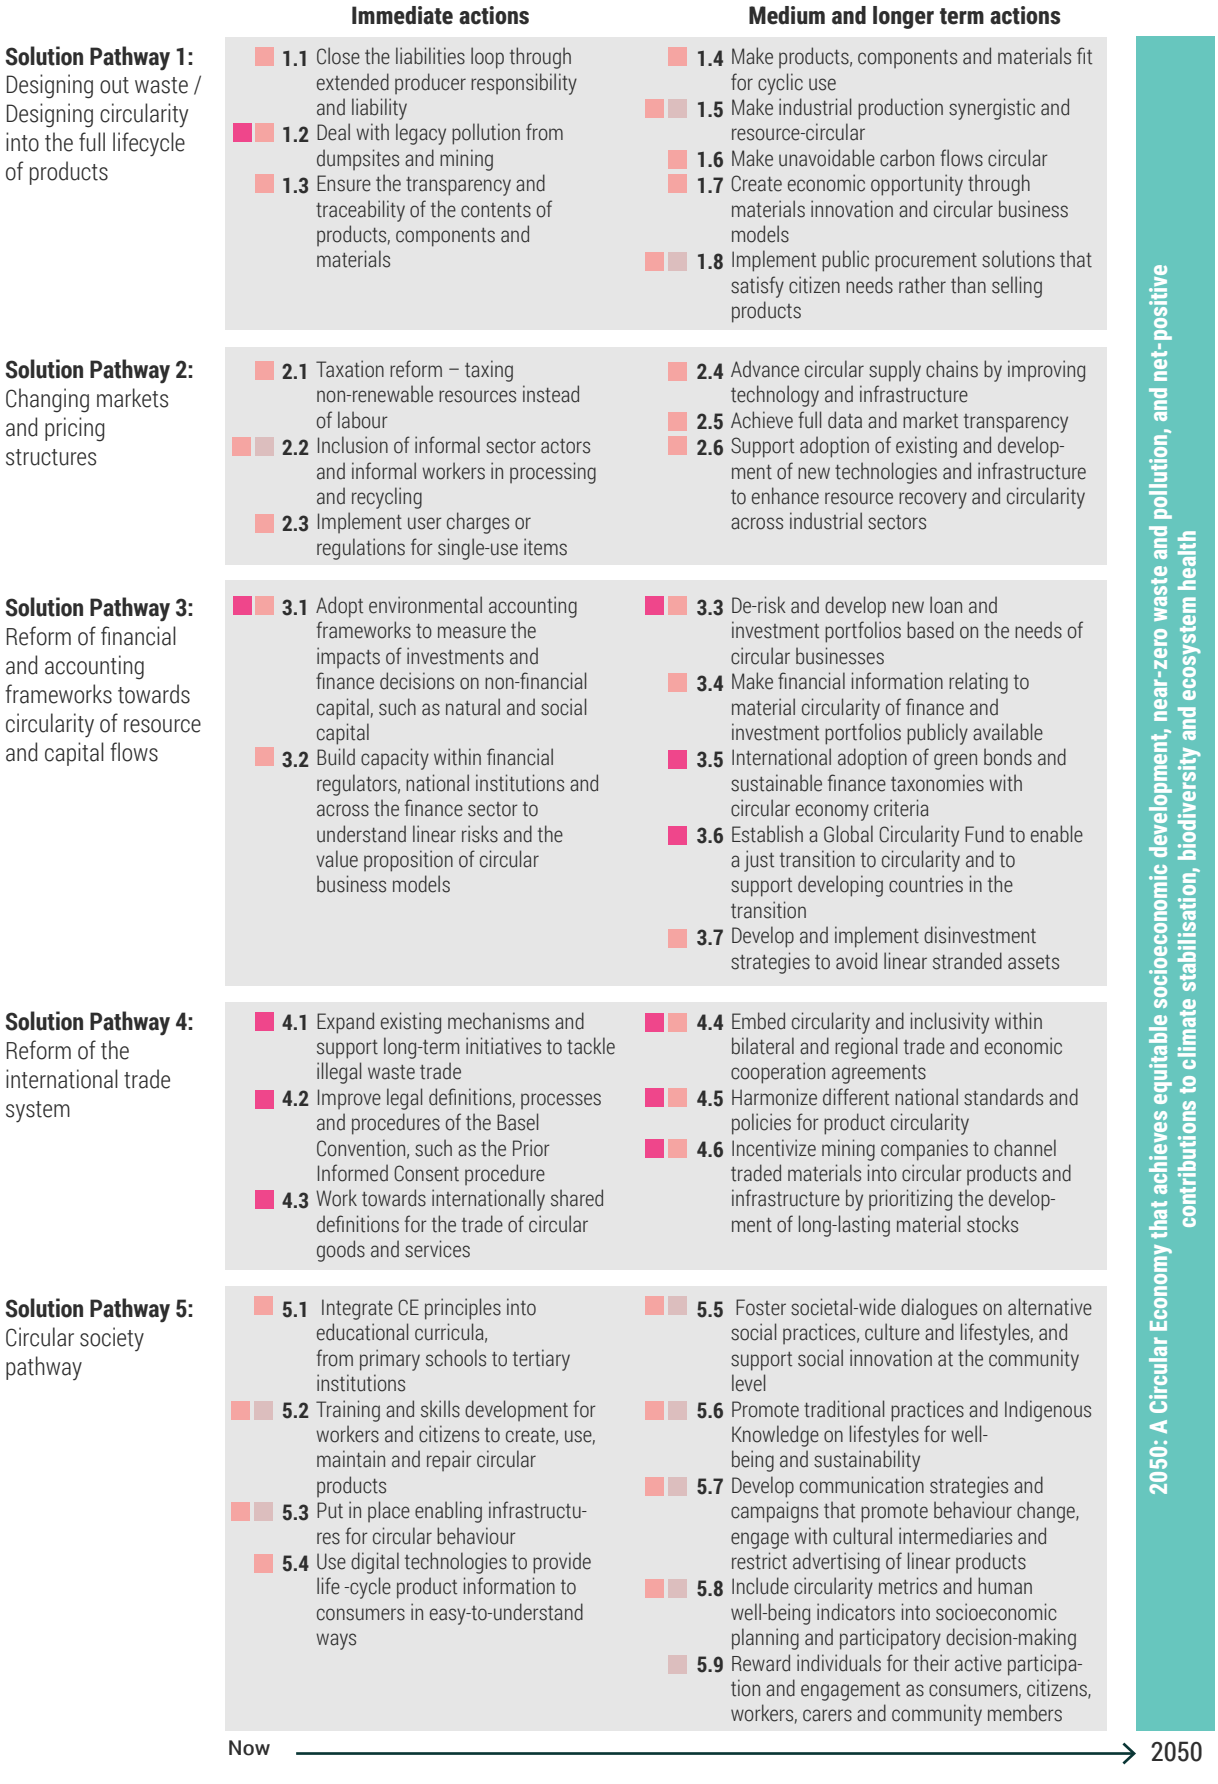


Figure 15.6: Closing the loop: Transforming systems through circularity

Creating fair and effective markets for circular goods and services

Objective: Establish transparent and efficient markets for circular goods and services, ensuring equitable participation and scaling of circular business models.

Use digital technologies like blockchain for traceability and transparency in value chains.

Reform taxation to incentivize circular economy practices and discourage non-renewable resorce use

Support SMEs and informal waste sector integration through capacity building and access to finance.

Ensure socially just transitions, especially for vulnerable groups, through legal protection and financial support.

Enabling transparent and fair global trade systems

Objective: Establish trade systems that facilitate the movement of circular goods and prevent illegal waste dumping, fostering global circular economy development.

Repurpose subsidies from extractive sectors to resource recovery and circular business models.

Develop technical guidelines and digital customs processes to improve interoperability across countries.

Expand international agreements and law enforcement to tackle illegal waste trade and promote legal, efficient transboundary movement of secondary resources.

Embed circularity provisions in trade agreements to encourage preferential treatment for circular goods.

Action 1: Close the liabilities loop through extended producer responsibility and liability

Extended producer responsibility (EPR) policies are a key approach to providing much-needed funding for municipal waste recycling while also facilitating material recovery and increasing recycling rates. More than 63 governments have implemented EPR policies, covering seven main industries, including packaging, textiles, electronics and electrical equipment, over the last 20 years (OECD 2001; Kunz, Mayers and Van Wassenhove 2018; Mallick et al. 2024; Brown et al. 2024). EPR schemes are the first step for governments to involve the private sector in covering end-of-life costs, enabling recycling and preventing pollution (Pouikli 2020). In India, the EPR Policy was first introduced and implemented in 2011 through the "E-Waste (Management and Handling) Rules" that made it mandatory for producers to manage their electronic waste (Ministry of Environment 2011). In 2016, the policy was expanded to include plastic waste management by local bodies, Gram Panchayats (village level self-government), waste generators, retailers, and street vendors.

To enhance EPR systems and promote eco-design, eco-modulated fees adjust the financial contributions that producers make to producer responsibility organizations based on the environmental performance of their products (Arya and Bhutani 2023). This incentive rewards circular design choices with lower fees, while products with lower recyclability and higher environmental damage incur higher charges (Lifset et al. 2023). Governments and existing producer responsibility organizations play a key role in elevating EPR towards transformative extended producer liability regulations. Action 1 is closely linked with other actions that follow, including Action 3, digital product passports and fitness for circularity, and Solution pathway 2's Action 3, data and market transparency.

Building on EPR policies, new concepts such as extended producer ownership or total product liability further shift responsibility to the manufacturers, brands and retailers (Domenech and Ekins 2019; Stahel 2019). This becomes the foundation of a comprehensive circular economy in practice: encouraging the management of material stocks and their quality, as well as utilizing whole value chain transparency. Applying the polluter-pays principle, an additional sum is added to a product's price to reflect potential recovery costs for materials that appear as waste. EPR and liability promotes business model and material innovation and provides a gateway to constructively allocating full cost pricing (Kunz, Mayers and Van Wassenhove 2018; Domenech and Ekins 2019; De Sadeleer 2020; Pouikli 2020).

Action 2: Deal with legacy pollution from dumpsites and mining

The linear economic model has created a dire legacy of waste and pollution, with chemically hazardous sites jeopardizing public health and safety. The world's 50 largest dumpsites affect the daily lives of 64 million people (ISWA 2016; He, Wu and Zhang 2016). Open dumping of waste contributes to chemical pollution, especially in developing countries in Sub-Saharan Africa, Latin America, and Oceania, mainly due to a lack of collection services (UNEP 2024c). Legacy pollutants leaching out of contaminated sites are a leading cause of failing water quality targets in aquatic ecosystems (Choo et al. 2020). With municipal solid waste generation rates set to increase in developing countries, systems for the collection and disposal of uncontrolled waste must be strengthened and modernized (Adiansyah et al. 2015; UNEP 2024c).

Addressing the issue of data availability and the lack of standardization in measurement and reporting from dumpsites remains critical (OECD 2024a). Technologies such as remote sensing can detect dumpsites and collect information for the analysis of landfill evolution and potential damages (Hannan et al. 2015; Khan et al. 2022; Papale et al. 2023). At an industrial level, one solution is landfill mining, where valuable raw materials and energy are extracted from existing dumpsites. This approach mitigates landfill emissions and increases landfill capacity (Wagner and Raymond 2015; He, Wu and Zhang 2016; Hogland, Marques and Nimmermark 2004; Ojha et al. 2024). Approaches for remediating heavy-metal-contaminated sites include treatments such as soil washing and in situ immobilization (Zhai et al., 2018), a process whereby contaminants are separated from the soil matrix, and thermal desorption, which utilizes heat to vaporize and capture organic pollutants.

In the mining industry, the handling and storing of toxic tailings at extraction sites is inadequate (Global Tailings Review 2020). Current methods include disposal into rivers and oceans, retention in wetlands, backfilling into mined-out areas, dry stacking, and storage behind dams (Lottermoser 2010; Watson et al. 2010; Adiansyah et al. 2015). The re-mining of tailings has emerged as an approach to recover valuable minerals from mine waste, reducing the volume of stored tailings. Remediation strategies include containment barriers to prevent further spread, chemical additives to neutralize acidic drainage, and transferring contaminated materials to designated

Credit: duallogic/Envato

storage areas after cleaning (Engels et al., 2004; Kossoff et al., 2014; Park et al., 2019). Government regulation is key: China has established environmental investigations and risk assessments to prevent pollution from mining tailings (Government of China, 2022), while Brazil has developed guidelines for their proper disposal (Kossoff et al., 2014; Government of Brazil, 2022;). However, greater government action is required to address and remediate legacy pollution at mining sites globally (World Bank 2023).

Action 3: Ensure the transparency and traceability of the contents of products, components and materials

A materials and product passport is effective in recording the content of products, components and materials from supplier to buyer or user through to the end of the first life cycle, enabling recovery and reuse (Göswein et al. 2022). Product designs that use fewer materials facilitate this. Digital product passports (DPPs) are already being mandated, such as the European Union's Battery Regulation for lithium-ion batteries used in electric vehicles, which is due to take effect in 2026 (European Commission, 2023a). China introduced the Interim Provisions on Traceability Management of Power Battery Recycling in New Energy Vehicles in 2018 and is currently developing a battery passport (IEA 2025). International cooperation will be needed to establish common standards for battery DPPs (World Economic Forum 2023). The European Union's Ecodesign for Sustainable Products Regulation, which aims to improve transparency along product value chains by offering detailed information on each product's origin, materials, environmental footprint and disposal guidance, will likewise require international coordination (European Commission 2023a; European Commission 2024).

DPPs should declare details about the product's lifetime and residual longevity, including any previous defects and repairs. Ensuring transparency and traceability of materials will be key to enabling circular supply chain management and preventing greenwashing and unsubstantiated environmental claims (Zhang and Seuring 2024; Choudhury, Islam and Sujauddin 2024). Building on existing initiatives, an international multi-stakeholder initiative co-convened by UNEP and the International Telecommunications Union would be well-positioned to define an internationally agreed framework and protocol on what information DPPs should contain. Developing countries will require targeted support in building capacity for the adoption and use of DPPs, particularly for small businesses and those in the informal sector.

Action 4: Make products, components and materials fit for cyclic use

With stock management and lifetime extension in mind, design for durability, repair, remanufacture, refurbishment, and even design for disassembly and reassembly are the hallmarks of circular product design (Abuzied et al. 2020). These design approaches offer new business opportunities, especially in providing the use and access to products instead of ownership, including through product-as-a-service models (Olivetti and Cullen 2018; Fernandes et al. 2020). Ending practices that undermine circularity must be prioritized, such as spare parts restrictions, suspension of services for updating software, or lock-ins that force customers to stay within a specific brand's system (Poppe et al. 2021). Standardized product design and product lifespan requirements can act as strategies against planned obsolescence (Prakash et al. 2020).

The ability to recover high-quality materials from end-of-life products is essential for circularity, especially where extensive material stocks have accumulated. This also speaks not only to materials and product passports but also to design for disassembly (Talens Peiró, Ardente, and Mathieux, 2017). Multi-stakeholder processes convened by international standardization bodies, such as ISO and the European Committee for Standardization, together with business associations, independent scientists and engineers, will need to further develop circular design guidelines at the sectoral and product levels. National and subnational regulatory agencies need to ensure compliance with such standards for trade within and across their jurisdictions (Maiurova et al. 2022).

Action 5: Make industrial production synergistic and resource-circular

Cross-sectoral cooperation through industrial symbiosis, industrial hubs for circularity or similar schemes to facilitate effective resource usage and create synergies between industrial actors, public entities and regional communities are needed (Mendez Alva, De Boever and Van Eetvelde 2021). The sharing of energy, materials, services, infrastructure, and information is central to such schemes, and participants co-create mutually beneficial solutions (Chertow and Ashton 2009). Some common interlinkages are the uptake of by-product materials considered waste by another entity, the pooling of resources, and shared energy supplies (Chertow 2000; Neves et al. 2020; Lybæk, Christensen and Thomsen 2021). Public and private initiatives have both successfully driven industrial symbiosis implementation (Domenech et al. 2019). A variety of policies, financial incentives, and knowledge transfer mechanisms can encourage the private sector to take the lead or get engaged (Mortensen and Kørnøv 2019; Lybæk, Christensen and Thomsen 2021). Standardized data facilitated through digital knowledge centres, AI-based tools and industrial ecology methods, such as material flow accounting, can support allocating resources across different value chains and anticipate resource needs more accurately. Digital applications such as blockchain technology aid small and medium-sized enterprises in embedding transparency and efficiency into their operations (Saavedra et al. 2018; Iranmanesh et al. 2023; Jawad and Balázs 2024). However, artificial intelligence and other digital solutions have their own environmental impacts that are still difficult to quantify (Kaack et al. 2022).

Action 6: Make unavoidable carbon flows circular

The pursuit of carbon circularity complements mitigation efforts, but it is not a substitute for the imperative of phasing out fossil fuels. Industrial sectors, such as the chemical industry, are heavily reliant on carbon derived from fossil fuel. There is a need for non-fossil-based carbon flows, which can be achieved by biomass-based solutions, along with recovery and valorization of unavoidable carbon flows. The cement industry alone is responsible for about 7 per cent of global CO_2 emissions, and a significant share is unavoidable (Mohamad et al. 2022; Monteiro and Roussanaly 2022; Supriya et al. 2023). CO_2 from point sources, such as cement or biomethane production, has the potential to be converted into hydrocarbons for the chemical industry, polymer feedstock, fuels, or food-grade CO_2 (Pan et al., 2020; Mohamad et al., 2022; Monteiro and Roussanaly, 2022; Ministerium of Transport Baden-Württemberg, 2022; Supriya et al., 2023). An example of an existing business activity is CO_2 recovery from biogas upgrading into biomethane, with valorization in the food and beverage industry or technical schemes that rely on CO_2 (Esposito et al. 2019). Solutions that chemically transform CO_2 into products based on carbon structures may be more prone to environmental burden shifting as they are energy intensive, and most of them rely on hydrogen.

Action 7: Create economic opportunity through materials innovation and circular business models

Novel materials, particularly those suitable as replacements for short-cycle, low-value, but hard-to-manage polymers or existing construction materials with high CO_2 emissions, are

still underexploited, despite a disruptive potential (Bucknall 2020; Sizirici et al. 2021; Labaran, Mathur and Farouq 2021). Mechanisms to promote such materials at the local, regional and international level are needed. Businesses and investors with long-term vision and patient capital can provide the needed investments to shift material science innovations from the lab to the market. Alongside circular supplies and resource recovery are digitally enabled models of selling products as services, product life extension and varieties of the sharing economy (Ferasso et al. 2020; Geissdoerfer et al. 2020). Such business models, much like materials innovation, become increasingly attractive if real cost pricing progressively disadvantages linear models of scale and sale, and if firms can leverage industry consolidation and use the opportunities afforded if transparency around materials and liability for materials recovery is increasingly allocated to manufacturers (Action 1).

Action 8: Implement public procurement solutions that satisfy citizen needs rather than selling products

Identifying and satisfying the needs of customers rather than selling product ownership disrupts the logic of the linear throughput economy. Such practices are usually linked to business models around access – for example, through performance agreements, pay-per-use, rental, lease and subscription – and are suitable for products that are used but not used up (Ogunmakinde, Sher and Egbelakin 2021; Gsell et al. 2024; Golinska-Dawson, Zysnarska and Pender 2024). However, continued product ownership across the full value chain remains key; access or service models per se are not sufficient for a circular economy on their own. Lowering costs and increasing profitability involves building in product durability, easing maintenance, supporting upgrades, and facilitating recovery, especially for products, components and materials of high value, and industries with high business concentration. In these highly concentrated industries, technological complexity and intellectual property often play a key role in limiting competition, which also creates challenges in managing economic rent-seeking (Webster 2021).

Government spending on public procurement amounts to 10–15 per cent of gross domestic product on average (World Bank 2021). Hence, government agencies and public authorities can leverage public procurement to shift from purchasing products to procuring services – such as leasing office equipment, using pay-per-use lighting systems and adopting shared or rented vehicle fleets – thereby promoting resource efficiency and circular economy principles. Under the green procurement policy in Denmark, the Partnership for Green Public Procurement, a collaborative initiative between Danish regions, municipalities, and the Ministry of Environment and Food, has integrated circularity into their procurement policies through criteria ranging from recyclability to product lifespan, and total cost of ownership (OECD 2024b). Donations of used computer equipment from the public sector to communities can help reduce digital exclusion (Good Things Foundation, 2023). Circular procurement guidelines have been published by UNEP (UNEP 2018b) in reorientating spending towards low-energy transport choices in including repair, reuse and refurbish, rather than buying new. Reworking procurement criteria for local authorities and associated anchor institutions enables local providers to use public procurement as a way to support local economic development. This approach prioritizes community wealth building by redirecting local government spending and resources via participatory decision-making to benefit the local economy (Community Wealth Building 2021).

15.2.2 Solution pathway 2: Changing markets and pricing structures

This pathway aims to create markets for circular goods and services by addressing market signals and pricing structures so products, components and materials are maintained at their highest value for as long as possible. Reusing products and components and recycling materials that retain their integrity and value makes them cheaper over their life cycle than primary materials. This is, however, currently not reflected in markets and prices. For example, in January 2024, recycled polyethylene terephthalate was priced at US$1,000 per ton, while primary plastic was around US$800–900 per ton (Hicks 2024). Recycled cotton textile fibres are roughly double the price of conventional cotton (Marini 2024).

This disparity is compounded by subsidies, both direct and indirect, in exploiting fossil fuels, mineral resources and other forms of natural capital, further distorting costs and prices. The estimated environmental cost associated with certain subsidies far exceeds their monetary value. According to the International Monetary Fund, when factoring in the adverse external effects stemming from fossil fuel subsidies, the combined cost amounts to approximately US$5.2 trillion per year (Coady et al. 2019). At the same time, in most countries labour is overtaxed compared to capital gains, for example, as it is the factor bearing most taxation, alongside consumption (OECD 2018).

A mature circular economy is based on stock or capital maintenance rather than revenue and throughput. Shifting taxation to pollution and waste and to non-renewable resource use shows positive outcomes in key indicators like employment, energy use and economic growth, even where the proposals are broadly revenue neutral. A comprehensive study for the European Union context broadly indicates the feasibility and potential (Groothuis 2022) of shifting €526 billion from labour to resource use by 2025.

Another example is the Mining Royalty bill in Chile, which came into effect in 2024, imposing a 1 per cent tax on lithium and copper mining. The revenue generated will be distributed across the country through three dedicated funds aimed at supporting municipalities and low-income communities. These funds are designed to help mitigate the negative environmental and social impacts of mining activities, including pollution and the disposal of mine tailings. By placing a cost on resource extraction, the royalty serves as an economic disincentive for over-exploitation and helps internalize the environmental costs associated with mining (IEA 2023).

As alternatives to resource taxation, several market-based instruments can effectively reduce material consumption and waste generation. One option is to implement a cap on the total amount of virgin materials allowed to enter the economy, combined with a system of tradable permits allocated to producers or importers. Such measures would create a controlled supply and a market incentive to use fewer raw materials. Another approach involves introducing material efficiency credits, where companies are rewarded for reducing material use or improving product circularity.

There is no guarantee that jobs created in a circular economy will be inherently just and well-paid. For a successful and inclusive circular economy transition, considerations of justice and social equity are as important as they are in the contexts of low-carbon transitions and digitalization of the economy. Without considering social justice, the transition to a circular economy will face challenges in establishing itself as a new economic model and will lack public acceptance and support as a sustainable alternative (Schröder 2020). Tax shifting away from labour and support-related statutory elements around minimum wage or living wage can be expected to maintain or boost spending power, other things being equal. The low-income response might be in circulating fees taken from resource rents as one form of compensatory lift to citizens' income (Miller and Hansen 2019). A reduction in income tax and social security contributions would ease the burden on households, while income support and social safety nets would help low-income groups. Such adjustments will be the cornerstone for a socially just transition.

Action 1: Taxation reform – taxing non-renewable resources instead of labour

Taxing non-renewable resources instead of renewable resources, such as human labour, is an important policy lever to advance resource efficiency and circularity (Groothuis 2014; Vence and López Pérez 2021). The current taxation system favours new product manufacturing activities that are increasingly highly automated and generally materials and energy intensive while penalizing circular economic activities that are generally more labour-intensive, such as repair and service models (Vence and López Pérez 2021). Taxing the value of common resources, such as materials and non-renewable energy sources, and access to waste sinks including the atmosphere, would promote low-carbon and low-resource solutions and a shift towards a circular regional economy, as opposed to the linear global economy. Additionally, a taxation shift could result in substantial improvements in material and energy efficiency, regional job creation, and national greenhouse gas emission reductions (Milios 2021).

The lack of progress appears to be a combination of the political difficulty of making any changes to a country's tax system and its distributional consequences (Pisani-Ferry 2021). For instance, taxes on carbon could be redistributed through a universal basic dividend, addressing all low-income groups and easing concerns about opposition or social unrest (Webster 2022). Set at an appropriate level, this dividend would go beyond merely compensating for necessary price rises. For instance, as part of the Baker-Shultz Carbon Dividends Plan, an annual carbon dividend of US$2,000 for a family of four has been proposed for US citizens (Climate Leadership Council, 2024). Tax reform could be fairly structured to account for different income levels by applying lower tax rates to lower-income groups and higher rates to those with higher incomes.

At the same time, destabilizing non-circular practices relies on levying taxes on landfills and incineration. This is the most common economic instrument in many countries, with 22 European Union Member States implementing these taxes (European Economic Area

Credit: recstockfootage/Envato

2023). National taxation departments, treasuries, and Ministries of Finance will need to anchor these changes in their annual budgets as new government revenue streams. In the short term, viable options include VAT exemption on repair, refurbishment and removal of tax benefits for linear economic activities while phasing in incremental taxes on primary extraction of non-renewable resources.

Action 2: Inclusion of informal sector actors and informal workers in processing and recycling

Making secondary raw material markets work requires the inclusion of the informal sector, which plays a key role in collecting, sorting, processing and recycling of many material and waste streams. The integration of informal actors, particularly waste pickers, is crucial for addressing precarious working conditions and social inequality, as well as for developing circular modes of production and supply chains that can compete in global markets (Dewick et al., 2022). Within many developing economies, waste pickers are key stakeholders who must be actively included, as the informal sector plays a crucial role in circular value chains, encompassing activities such as collection, trade, repair, reuse, recovery and recycling of goods (Sun, Schnoor, and Zeng, 2022).

Of major concern are the circularity-oriented practices that increase risks to human and environmental health. Such practices are often associated with informal sectors and are prevalent in all regions worldwide, particularly in economically less-developed countries. Many informal waste collectors in less-developed countries are women, which increases their exposure to waste hazards (Cottom, Cook, and Velis, 2024).

Generally, these activities offer economic and entrepreneurial opportunities for individuals engaged in the informal sector. However, workers often face precarious working conditions, health risks, inadequate legal protection, and insufficient economic benefits (Buch et al. 2021). A circular economy where materials recovery and recycling are achieved by exploiting the informal sector is not acceptable. Without adequate infrastructure, it is difficult to envision a circular economy that supports decent work, well-being and human needs. Infrastructure that allows for added value and returns to local businesses and enterprises would be a substantial and significant addition (Preston City Council, 2019).

The first step in facilitating a covenant relationship with municipalities and the informal sector is the formation

of cooperatives or other legally or partially recognized structures (Gupta 2012). This multi-faceted process requires several policy, economic and institutional measures (Aparcana 2017), including a regulatory framework that incentivizes and safeguards informal workers. Measures could include providing ease of registration, reducing bureaucratic hurdles, offering safety nets in the form of insurance, as well as financial and technological support (Gupta 2012; Aparcana 2017). An example of hybrid waste management emerged in Buenos Aires, where dry-waste scavenging is formalized into cooperatives, and value added equipment and infrastructure are provided, while wet organic waste is managed by large-scale contractors (Knowledge Hub 2020). Training and capacity-building initiatives are crucial and must outline the duties and accountabilities of waste generators at all levels of the waste management system (Adiansyah et al. 2015) and society (Mor and Ravindra 2023). For example, in Bamako, community-based private enterprises acted as intermediaries between the local associations and the municipality, engaging in outreach to households and organizing training sessions for the government, economic interest groups, health committees, and informal workers (World Bank 2023).

Action 3: Implement user charges or regulations for single-use items

In a circular economy, implementing user charges, deposit-return schemes, or bans on single-use products such as plastic packaging and containers serves as a deterrent to wasteful consumption, promotes innovation in product design and supply chains (Syberg et al., 2021), and counteracts environmental littering (European Commission, 2018). Charges also internalize external costs on society, such as those associated with pollution, waste and natural resource depletion, and can fund investments in the circular economy. This approach requires effective legal measures at the country level, including the introduction of alternatives for banned or disfavoured items.

Action 4: Advance circular supply chains by improving technology and infrastructure

Investment in technological solutions is essential for facilitating the tracking, recovery and management of materials across various supply chains, including electronics, textiles, automotive, and construction materials for the built environment (Garrido-Hidalgo et al. 2020Ni, Chan and Tan 2023). Implementing digital technologies, such as big data and Internet of Things devices, can optimize the tracking of secondary materials (Krstić et al. 2022) by gathering real-time information and mapping collection points with the highest waste generation (Centobelli et al. 2022; Mallick et al. 2023). A logistics technology system, combined with an optimized and interconnected transport infrastructure (Garrido-Hidalgo et al. 2020; Kaewunruen et al. 2023) is crucial for the adoption of reverse logistics. This system would include both information and physical infrastructure, such as collection and processing points, to ensure efficient resource recovery and waste management. Enabling effective partnerships among distributors, suppliers and logistics companies is crucial for establishing robust networks.

Action 5: Achieve full data and market transparency

A major barrier to markets for circularity is the inadequate transparency and traceability of product value chains. This hinders the effective tracking and reporting of material flows, as well as providing comprehensive information on products and their impacts (Serna-Guerrero et al. 2022). The establishment of traceability mechanisms within the circular economy will enable the amalgamation of supply chain information-sharing and visibility, thereby granting stakeholders access to accurate, trustworthy, timely and operationally valuable information. Traceability ensures the accuracy of sustainability claims and facilitates the retracing of steps, verifying processes, history and location of products, aiding in recovery and recycling at the end of life.

The circularity transformation will need to leverage innovative technologies such as artificial intelligence, data-collection platforms, digital passports, the Internet of Things (Hakanen and Rajala 2018) and blockchain solutions to augment the traceability and transparency of product value chains (Centobelli et al. 2022). The integration of digital advances encourages systemic transformation by improving the economic and environmental sustainability of products throughout their entire supply chains. These digital tools can aid in the reduction and recovery of waste and optimization of production, processing and logistics, as well as the enhancement of overall visibility. Examples include the circular value chain traceability protocol for garments and footwear, developed by the United Nations Commission for Europe (UNECE 2023b). This traceability can be further strengthened through mandatory DPPs that track the entire product value chain (Walden, Steinbrecher and

Marinkovic 2021). DPP adoption is particularly relevant in sectors such as electronics and textiles, where there is a lack of transparency, supply chain collaboration, and comprehensive information on composition, producers and origin. At the same time, increased transparency about the resource and energy demands of digital tools employed for traceability is important in ensuring that any adverse environmental consequences do not outweigh the benefits of circularity (European Commission 2023b).

Action 6: Support adoption of existing and development of new technologies and infrastructure to enhance resource recovery and circularity across industrial sectors

Many technologies that can increase circularity and even closed-loop systems already exist, but they are not commonly adopted to the scale needed. Barriers to their transfer and adoption include a lack of awareness among industry stakeholders, a lack of technical capability among the workforce, and limited government support (Ren et al., 2023).

High-volume material streams, such as e-waste, need to be managed through repair, remanufacturing and recycling at the end of their life to enable full circularity. Dismantling, crushing and screening are commonly applied to separate components and enable the recycling of, for example, metals and plastics, typically followed by pyrometallurgical processing in developed countries and hydrometallurgical processing in developing countries to recover different metals (Li et al. 2015). Minority components, such as rare earth elements, largely remain unrecovered due to their challenging economic viability (Andersson et al. 2019). New technologies and infrastructure for large-scale recycling, specifically for metals and critical raw materials, require research and development as well as investment.

In the textile and garments industry, new technologies are emerging to reduce textile waste, recycle textile fibres, phase out toxic substances, and reduce workers' and consumers' exposure to harmful materials such as per- and polyfluoroalkyl substances, but they still need to be brought to market (Reike, Hekkert and Negro 2023; Bour et al. 2023).

Wastewater technologies can facilitate the recovery of secondary resources, which applies to both industrial and municipal water. Biological and physio-chemical treatment methods are widely used to decontaminate wastewater before discharge into the environment. Microorganisms, such as bacteria, fungi (Abinandan and Shanthakumar, 2015), and microalgae (Kalra, Gaur and Goel, 2021), are effective biological agents. In contrast, industrial effluents often require alternative or additional physicochemical processes, including membrane filtration or electrochemical treatment. Advanced filtration systems and reverse osmosis improve the quality of treated water, while emerging technologies, such as membrane bioreactors, enhance contaminant removal and optimize energy recovery processes (Zhang, Wang, and Li, 2020). State-of-the-art solutions include combining wastewater treatment with nutrient recovery, such as phosphorus and nitrogen, for agricultural use (Zhu, Cakmak and Cetecioglu 2023). The anaerobic digestion of resultant sludges can cover some of the high energy demands of wastewater treatment plants (Khawer et al. 2022). Additional circularity schemes, such as the production of polymers or other value added bioproducts from wastewater constituents, need to be advanced towards market competitiveness (Capodaglio 2023).

More widespread adoption of such practices and technologies across different regions would stimulate transnational governmental initiatives for technology transfer and investment in recycling infrastructure. Industrial research and development engagement, as well as regulatory frameworks and financial incentives, will be crucial (15.2.3).

15.2.3 Solution pathway 3: Reform financial and accounting frameworks towards circularity of resource and capital flows

The transformation to a circular economy at scale requires making financing circularity the new normal in mainstream financial instruments and government spending. According to the UNEP Finance Initiative (UNEP-FI), "financing for circularity covers any type of financial service where money is exclusively used to finance, re-finance, invest in or insure in part or in full, new and/or existing companies or projects that advance the circularity of our economies" (UNEP 2020a). There are interlinkages among circular economy finance, responsible banking and finance for climate and biodiversity, where circular economy finance can act as an enabler (United Nations Development Programme 2024).

Despite the recent emergence of new models and frameworks for circular economy finance, both public

UNEP's Textile Initiative supports Small and Medium-sized Enterprises in minimizing the environmental footprint of their textile products
Credit: ©UNEP

and private circular spending remains small-scale in comparison with climate finance and spending in the linear economy, with insufficient funding for circular business models, large-scale recycling infrastructure and technology innovation to drive a global transition at scale. Although financial data availability remains very limited, initial estimates show that only about 4 per cent of global total government spending of US$13 trillion in 2019/2020 was circular, rising to 5 per cent when COVID-19 pandemic stimulus spending is included. Corporate sector linear economy spending was about US$35 trillion in 2019/2020, with the circular economy's share of this only about 3 per cent each year (Schröder and Raes 2021; Lawlor and Spratt 2021).

Circular economy finance still suffers from unclear definitions of what constitutes circular investments and ambiguous or poorly defined metrics to evaluate investments and assess whether an activity, company or project contributes to circularity. Overall, most information about the environmental and social outcomes of circular investments is still inadequate. To avoid the risk of circular economy finance losing its effectiveness as it develops, for example, through the use of vague metrics and imprecise indicators, more oversight and benchmarking by regulators and financial standards bodies is required (Dewick et al. 2020).

Several initiatives are developing technical criteria to define circular economy finance. In the Kingdom of the Netherlands, the FinanCE working group consisting of private banks such as ABN AMRO, ING and Rabobank introduced the Circular Economy Finance Guidelines, which contain prescriptions on the use of investments, impact assessment and process evaluation (FinanCE 2018). Banks are developing internal circular economy standards, metrics and instruments to measure the level of circularity of investments and clients (Intesa San Paolo 2022). UNEP-FI has developed support tools for financial institutions to set targets for circular economy and resource efficiency and to embed circularity in climate action plans (United Nations Development Programme Finance Initiative, 2023; United Nations Development Programme Finance Initiative, 2024).

A road map for circular finance for 2030, developed by a multi-stakeholder group including financial institutions and experts (Circle Economy, 2022), highlights the need to assess both existing linear risks associated with existing economic systems and new circular risks, such as the economic viability of circular business models. The linear risk of continuing to do business under the unsustainable assumption of infinite resources must be explicitly included in financing decisions. One of the current obstacles to scaling up investments into

circular technologies and business models is the perception of high-risk investments and low returns for investors. Insufficient investment and the perceived risks associated with circular business models hinder progress towards a circular economy, particularly for small and medium-sized enterprises and start-ups, which account for the largest share of businesses with financial needs (Aranda-Usón et al. 2019).

Circular economy road maps provide the strategic direction and investment priorities that are essential for driving financing solutions. Effective implementation will require funding from both public and private sources, particularly for national action plans and policies. For example, Lithuania and Spain have estimated a required budget of around €4 billion and €1.5 billion, respectively, to deliver on the circular road map and strategy commitments. Spain dedicated €850 million from its COVID-19 recovery and resilience plan to support its circular economy strategy. Circular economy road map financing for developing countries remains a particular gap; for example, Rwanda estimated the need for US$211 million (Ministry of Environment, Rwanda and UNDP 2022), while Ghana estimates US$2.5 billion (Barrie et al. 2024).

The following actions are proposed to scale up existing circular finance initiatives, address barriers to mainstreaming circular finance and enable a shift in financial risk-assessment and accounting frameworks.

Action 1: Adopt environmental accounting frameworks to measure the impacts of investments and finance decisions on non-financial capital, such as natural and social capital

Current accounting practices and frameworks are rooted in an economy in which value is created by physical capital, a hallmark of the industrial linear manufacturing economic era (Watson, Zochowski and McGarvey 2021). A broader focus on non-financial capital, known as intangibles, in accounting practices and reporting can help reflect the full value of circular investments and companies, exposing the effects, risks and liabilities of extractive practices and linear business models (Ellen MacArthur Foundation 2020). The circular economy can be a de-risking strategy for investors and businesses. During the COVID-19 pandemic, European circular businesses and assets demonstrated stronger financial performance and were more effective at mitigating negative impacts than their non-circular counterparts (Zara, Bellardini and Gobbi 2021). One of the key barriers to attracting most institutional investors, such as pension funds and insurance companies, to invest in natural capital is the lack of financial returns (Lamont 2021). Instead, investments in regenerative solutions that build natural capital have financial benefits in terms of avoided costs and a wider range of beneficiaries, not only the investors. Organizations such as the International Accounting Standards Board and the International Sustainability Standards Board, along with financial regulators, including central banks, play a key role in developing and adopting internationally accepted financial accounting frameworks that support circular and nature-positive finance (International Accounting Standards Board, 2021). Including the effects of investment on natural and social capital will be crucial in highlighting the social and environmental costs of investment decisions and direct investments towards regenerative solutions that rebuild natural capital.

Action 2: Build capacity within financial regulators, national institutions and across the finance sector to understand linear risks and the value proposition of circular business models

Building capacity will involve increasing targeted training for accountants, legal specialists and fiscal experts to navigate the added layers of complexity that circular economy investments entail. Enhanced understanding and capacity are key to enabling financial institutions to develop and offer new financial products for circularity. The financial industry, corporate clients and investees will need to actively engage with and build awareness of resource efficiency, the circular economy market, material flows and changing consumer demand. Risk policies can be adapted to manage linear risks and identify circular business opportunities by applying the 9R model in risk policies, financial product development and client engagement (UNEP 2020a). Finance institutions must develop training courses and materials to retrain staff and risk analysts. Similarly, universities should incorporate circular finance modules into their curricula to train the next generation of experts and risk analysts. To achieve this, universities should be encouraged to develop specialized programmes in circular finance, particularly within non-environmental faculties such as economics, law, administration, accounting, finance and business, focusing on regenerative solutions that restore and enhance natural capital.

Action 3: De-risk and develop new loan and investment portfolios based on the needs of circular businesses

Developing appropriate financing solutions with more risk capital for early-stage circular companies, small and medium-sized enterprises, and start-ups will be essential. Blended finance instruments that leverage both public and private sector resources can help mitigate risks associated with circular business models and accelerate the diffusion of technology. Blended finance reduces risk exposure and improves the financial feasibility and economic profitability of circular investment projects, especially in developing countries, while innovative investment portfolios can also address the risks and returns associated with regenerative practices (Nature Positive Initiative 2025). Supported by local and national government actions using concessionary finance, blended finance can attract commercial capital into the waste management sector in developing markets and make them more attractive to investors (Systemiq 2023). An example of such a finance mechanism is the African Development Bank's trust fund designed to integrate circular economy principles – the Africa Circular Economy Facility. Established in 2022 with support from the Government of Finland and the Nordic Development Fund, the facility also receives backing from corporate foundations (Africa Circular Economy Facility 2025).

Especially for small and medium-sized enterprises, a combination of an organization's own financial resources, the availability of private credit, low-interest loans and public funding sources has had a positive effect on stimulating the implementation of circular economy initiatives in businesses (Aranda-Usón et al. 2019). Other strategies include reorienting loans and investments towards more circular technologies and business models, developing sectoral knowledge and competencies to identify best practices for circular economy business models and financing opportunities, and applying sectoral metrics in financial decision-making.

Action 4: Making financial information relating to material circularity of finance and investment portfolios publicly available.

Adopting circular metrics in financing and reporting will be necessary to increase transparency, enabling external verification and benchmarking and reducing false green claims (Circle Economy 2022). Circular finance metrics will need to include transition metrics and targets related to banks' support to companies shifting from linear models to circular business models (UNEP 2023b). Assessing and incorporating linear risks into financial decision-making involves thoroughly analysing the long-term risks associated with linear investments and developing incentive-compatible solutions to counter short-termism in investment decisions. Development and adoption of additional evaluation metrics will be needed to account for and reduce the risk of stranded assets linked to linear sectors (Schröder and Raes 2021). The outcome will be accurate, publicly available information relating to the circularity of finance and investment portfolios. Financial regulators, in close dialogue with commercial banks, multilateral development banks, and investment and pension funds, need to lead this action.

Action 5: International adoption of green bonds and sustainable finance taxonomies with circular economy criteria

Green bonds can facilitate investment into the circular economy by providing dedicated financing for projects that promote resource efficiency, recycling infrastructure and circular production models. For example, the Green Bond Guidelines in Japan that were updated in 2023 include eligibility criteria aligned with the country's Sound Material-Cycle Society strategy, supporting projects such as recycling systems and resource-efficient manufacturing (The Ministry of the Environment Japan 2025). Multiple countries have adopted sustainable finance taxonomies to shift investments towards circular economy activities and businesses. The International Platform on Sustainable Finance has furthered work on the Common Ground Taxonomy, which contributes to the development of technical criteria and extends their scope and coverage (International Platform on Sustainable Finance 2023). Industry initiatives such as the Partnership for Carbon Accounting Financials and their GHG accounting and reporting standards for the financial industry also support taxonomy developments (Partnership for Carbon Accounting Financials 2021). International taxonomy harmonization and adoption will enable the use of classifications across countries and value chains on circular activities and investments. Cross-jurisdictional interoperability and comparability of taxonomies will need to align with environmental policies. As part of the environmental objectives and technical screening criteria in taxonomies, circular economy metrics need to be developed and adopted

across countries and jurisdictions. As countries work towards standardizing taxonomy frameworks, leveraging digital tools and technologies such as blockchain, artificial intelligence and data analytics can significantly improve the efficiency, transparency, and accuracy of circular economy metrics (Mair and Reilly 2020; International Platform on Sustainable Finance 2023). The stakeholders implementing this action will need to include national financial regulators, expert groups and financial institutions. To improve taxonomy usability and data infrastructure, governments and central banks will need to provide targeted financial and capacity-building support to stakeholders most affected by the taxonomies in terms of adopting the use of circular economy metrics, data-collection and reporting processes.

Action 6: Establish a Global Circularity Fund to enable a just transition to circularity and to support developing countries in the transition

Leveraging circular economy finance to support Sustainable Development Goals implementation will be crucial to achieving socially inclusive development and supporting developing countries. Explicitly including nature-positive goals in a Global Circularity Fund framework would support developing countries in adopting regenerative bioeconomy practices. Several multilateral development banks have already established lending portfolios focused on the circular economy. For example, the European Investment Bank provided EUR 3.4 billion from 2018 to 2022 to co-finance 118 circular economy projects in a variety of sectors, including waste management, industry and services and the bioeconomy (European Investment Bank 2023). This amount is minimal compared to total financing of EUR 65.15 billion in 2022 (European Investment Bank 2022). Circular development finance needs to scale up further to support value-adding economic opportunities in sectors such as remanufacturing and refurbishment and the recovery, recycling and processing of secondary materials. The Global Environment Facility highlighted the circular economy in the GEF-7 strategy within the International Waters and the Chemicals and Waste focal areas, as well as within the Sustainable Cities Impact Program (Global Environment Facility 2018). The Global Environment Facility can assist developing country governments in creating the enabling environments for private-public partnerships and effective regulations and public services. Multilateral development finance needs to prioritize projects that contribute to inclusive circular development to create jobs, empower, and address social and environmental challenges, aligning with broader just-transition objectives and the Sustainable Development Goals. For example, the G20's Global Infrastructure Hub has identified circular infrastructure as one of its priorities and will need to develop appropriate financing instruments (Global Infrastructure Hub 2023). Furthermore, a global circularity fund could cover financing needs to address global plastic pollution and link to mechanisms such as a "polymer premium" – a small standardized fee imposed on producers of primary plastic polymers that would be used to fund waste management in developing countries (Minderoo Foundation 2024).

Action 7: Develop and implement disinvestment strategies to avoid linear stranded assets

Given that most finance continues to go towards linear extractive business models, lessons can be applied from the climate finance sector, such as disinvestment initiatives from fossil fuels (Plantinga and Scholtens 2021). Divestment should be considered a last resort; however, it may also be necessary for addressing challenges within the linear economy. New stranded asset classes are emerging, including plastics feedstock production, which carries high economic risks for banks that invest in companies that produce plastic (ClientEarth, 2022). Disinvestment strategies from business models of planned obsolescence and extractive sectors would need to complement the investments towards resource recovery businesses and manufacturers that design for product longevity. Potential changes in financial accounting will include adapting approaches to depreciation and residual value calculation for assets with multiple-use cycles.

15.2.4 Solution pathway 4: Reform of the international trade system

Achieving a near-zero waste circular economy will require significant changes in the international trade system. While local resource loops and circular solutions are essential, international trade of primary and secondary resources, goods and services remains crucial to meeting the demands of different countries and regions, ultimately enabling a more inclusive global circular economy.

Based on data from United Nations COMTRADE, the global value of trade in secondary materials, including

second-hand items, waste, scrap, and residues, increased from US$94 billion to US$302 billion between 2000 and 2020 (Chatham House, 2020). Circular trade encompasses any international trade transaction, either material or immaterial, that contributes to circular economy activities at the local, national and global levels. It includes trade in circular-economy-enabling goods, services and intellectual property; second-hand goods for reuse, repair, remanufacturing or recycling; refurbished and remanufactured goods; secondary raw materials (biotic and abiotic); and non-hazardous waste, scrap and residues (biotic and abiotic) that can be safely recovered or valorized (Barrie and Schröder 2022).

Circular trade offers many economic, environmental and social benefits. Trade in circular-economy-enabling goods, services and intellectual property allows countries and companies to access the necessary knowledge, skills and equipment to implement new circular business models or conduct reuse, repair, remanufacturing and recycling activities. Trade in used goods for reuse, repair or remanufacturing enables more affordable access to essential goods and services for those in secondary markets and generates local demand for industry and employment (Barrie et al. 2022). Trade in secondary raw materials and waste destined for recovery enables the aggregation of materials in areas of highest demand to maximize economies of scale, making it economically attractive to transform waste into resources for new production. Circular bioeconomy trade encompasses the exchange of biodiversity-positive goods and services, including products derived from regenerative agricultural practices and products contributing to ecosystem restoration.

However, poorly regulated trade in waste has negative implications. Many grey areas and loopholes currently exist in the global trading system, allowing for high levels of illicit waste shipments, resulting in pollution, and increasing human exposure to toxic chemicals. Illegal shipment of waste is a serious and growing crime globally (The International Criminal Police Organization [INTERPOL] 2020). It comes in many forms, including transporting waste through organized criminal networks, mixing different types of waste, declaring hazardous waste as non-hazardous, or classifying waste as second-hand goods (Tan et al. 2018; United Nations Office on Drugs and Crime [UNODC] 2022). While illicit waste trafficking generates an estimated US$10 billion to US$12 billion annually, the clean-up costs for local governments from waste crimes are often far higher (Financial Action Task Force 2021). Illegal waste shipments that manage to evade Customs inspections are commonly burned in open landfill sites or dumped in the environment, polluting air, waterways and soils and threatening the health of local communities.

In July 2017, China mandated a strict ban on waste imports for materials such as plastics, paper, glass, and even scrap metal (Ryter et al. 2021). Since 2018, countries in Southeast Asia, including Indonesia, Malaysia, Thailand and Viet Nam, have become the top destinations for both legal and illegal waste (UNODC 2024). Countries are taking unilateral action to tackle the issue. For example, in January 2025, Thailand banned the import of plastic waste, and Brazil banned the import of solid waste (Laville 2025; Baker McKenzie 2025).

Toxic e-waste is often shipped to developing countries where regulation is lax. China processed about 70 per cent of the world's e-waste in 2000; the rest went to India and other countries in Eastern Asia and Africa, including Ghana and Nigeria (Sun, Schnoor and Zeng 2022). The illegal export of e-waste from developed countries to developing countries poses significant environmental and health risks to humans. The World Health Organization has highlighted the serious health impacts of "digital dumpsites" and e-waste recycling on women and children, including adverse birth outcomes, impaired neurological development, and increased risks of cancer (World Health Organization 2024).

Trade in used linear goods can have mixed results and potential negative consequences, particularly for developing countries. High volumes of used goods can flood secondary markets, threatening local industries and overwhelming local waste management systems. Africa is the leading destination for second-hand textiles, with the Sub-Saharan region being the world's largest destination for second-hand clothing, receiving nearly 34 per cent of total world exports in 2021 (Fibre2fashion 2021). While it provides access to affordable clothing and creates job opportunities in trade, distribution, repairs, laundry services and upcycling, importing low-quality items has created a significant environmental challenge (Sumo et al. 2023). Overdependence on second-hand trade flows may also increase exposure to supply chain risks and shocks. As industrialized countries transition to a circular economy, the developing world continues to receive legacy second-hand goods created within the linear economy. Such trade risks locking

Credit: frimufilms/Envato

a domestic market into inefficient and hazardous products that potentially undermine local economic resilience and waste mitigation efforts.

A concerted global effort is therefore required to ensure the circular trade regime evolves in a way that fosters sustainable environmental outcomes, equity, inclusivity and mutually beneficial cooperation. The following steps and actions are proposed to overcome these challenges and create a circular trade system.

Action 1: Expand existing mechanisms and support long-term initiatives to tackle illegal waste trade

To genuinely tackle the trade in illegal waste, a long-term, well-resourced and globally coordinated approach to policing is necessary. Such an approach could build on the work by UNEP WasteForce (UNEP 2020b), the Green Customs Initiative and findings from the DEMETER Operation of the World Customs Organization (World Customs Organization [WCO] 2022). It would need to be coordinated by existing organizations working on the issue, including Europol, INTERPOL, the Secretariat of the Basel Convention, the UN Office on Drugs and Crime, UNEP and the WCO. Waste crime units require further funding and capacity-building to coordinate actions internationally and crack down on transnational criminal networks. Individual governments must also commit to promptly reporting incidents of illegal waste crime. Combating international waste trafficking will require mutual legal assistance, law enforcement cooperation and extraditions (UNODC 2022).

Action 2: Improve legal definitions, processes and procedures of the Basel Convention, such as the Prior Informed Consent procedure

At the global level, the Basel Convention, as a multilateral environmental agreement, has a particular focus on protecting human health and the environment by preventing shipments of hazardous waste from OECD to non-OECD countries. Several rules and procedures under the Basel Convention are ambiguous, and some Parties face challenges with domestic implementation, for example, in distinguishing the types of waste. The Basel Convention must establish clear legal definitions that distinguish between waste and secondary resources to ensure effective regulation and implementation. A key mechanism of the Basel

Convention for achieving transparent and effective transboundary shipments is the prior informed consent (PIC) procedure, which requires exporters of hazardous waste to obtain prior consent from the competent authority in the recipient country. Efforts are under way to develop a digital approach for PIC that would enhance certain aspects of the procedure, although additional measures will still be needed to address the remaining challenges. Building on existing efforts in this area, a dedicated capacity-building initiative is needed to support developing countries in establishing the necessary infrastructure, training and resources to implement and enforce PIC requirements effectively. Furthermore, national regulations need to align with international PIC requirements to prevent inconsistencies in waste classification and trade controls.

Action 3: Work towards internationally shared definitions for the trade of circular goods and services

Shared or mutually recognized definitions and classifications for circular goods are crucial for enabling efficient trade that supports the transition to a circular economy. Yet there remains an absence, or divergence in the interpretation, of definitions and classifications of goods in terms of their circularity (Barrie and Schröder 2022). International organizations like the World Trade Organization (WTO) and the International Trade Commission have important roles in ensuring that circular economy-relevant information is captured in transboundary trade flows in a way that is globally interoperable. The Harmonized System (HS) codes are a key pillar of the tariff infrastructure for international trade. These codes predate circular economy considerations and are currently considered limited for circular goods, requiring updates and improvement (UNECE 2022). As new circular product categories and innovations emerge in the coming years and decades, HS codes will need to be continuously revised. Alongside other measures, such as trade facilitation frameworks for recyclable goods and materials and new or revised classifications for circular-enabling goods, HS codes system reform will be a critical tool in scaling circularity at a global level (Barrie and Grooby 2023).

Action 4: Embed circularity and inclusivity within bilateral and regional trade and economic cooperation agreements

Bilateral and regional trade agreements are a potential vehicle for advancing the trade and circular economy agenda among willing trading partners (Yamaguchi, 2021). Embedding circularity across the full spectrum of trade and economic cooperation agreements will be necessary to transform the global trade system. Specific actions that governments can take in the short to medium term include strengthening the Trade and Sustainable Development chapters of trade agreements for circularity by including more explicit commitments to cooperation on circularity as an essential element of all future trade agreements (Blot and Watkins 2022). They can also encourage participation in the development and implementation of international circular economy standards, clarifying areas for mutual investment in the circular economy, such as preserving the right to establish non-discriminatory regulations and public procurement processes, as well as promoting best practices. Reducing tariffs on technologies essential for circular economy activities, such as advanced recycling, material recovery and pollution control, would be a critical step. These technologies, despite their substantial contribution to circularity, often face high import duties that hinder their wider deployment (Barrie et al. 2022; ISO 2022).

Action 5: Harmonizing different national standards and policies for product circularity

Diverse standards and definitions related to a circular economy impede trade and increase the cost of compliance of companies. The primary challenge in developing national circular economy standards and regulations is regulatory divergence and sometimes contradictory requirements across different jurisdictions. The classifications of hazardous waste, non-hazardous waste and non-waste goods destined for reuse, repair and refurbishment often differ from country to country. This divergence generates additional costs for companies and disincentivizes investment in circular solutions. This points towards mapping of national circular economy standards with implications for trade and countries moving towards greater alignment. Including a circular economy-related policy as an environmental category within the WTO notification system would help improve the mapping of circular economy standards and regulations. Building on the WTO's existing Trade and Environmental Sustainability Structured Discussions, where the circular economy is only covered by a

Credit: wirestock/Envato

working group, the WTO should raise the importance of circular trade by establishing a formal forum where countries can systematically and openly discuss and share circular policies (WTO 2025). Alongside this, support is required to build the capacity of countries to report more frequently and accurately on such policy developments (Barrie et al. 2022).

Action 6: Incentivize mining companies to channel traded materials into circular products and infrastructure by prioritizing the development of long-lasting material stocks

While the focus is currently on rents from the use of the products and materials, future value lies in building up a stock of materials over the coming decades in the built environment, infrastructure and technology assets. Circular trade will allow substantial resource stocks to accumulate, which in time could significantly increase in value and become traded commodities. Circular trade could alleviate the pressure of current mining companies focused on the extraction of natural resources and reduce dependence on primary raw materials. Shifts to materials and resource leasing models, as already practised for high-value materials such as platinum, could be applied to battery materials, ensuring materials return for recovery and reuse at the end of life. New materials-as-a-service models could encourage circularity and the building of stock across commodity value chains. It will require a commitment from product manufacturers to return these materials and components, and will motivate industrial design of finished goods with longer lifetimes (Mundell n.d.; Silverman 2024). Policies can incentivize mining sector actors through the adoption of performance-based contracts, where mining companies lease metals rather than sell them outright, or implementation of deposit-refund schemes, where companies recover financial guarantees if they retrieve and recycle materials at end of life. International resource leasing could contribute to transparent and accountable mineral resource governance (Hagan et al. 2021). Materials-as-a-service models would allow developing country governments and society more broadly to retain control over natural resources while providing incentives for stock management and circularity – thus enforcing circular economy practices along the value chain and promoting product innovation.

15.2.5 Solution pathway 5: Circular society pathway

Citizens play a critical role in creating a circular society (Jaeger-Erben et al. 2021; Böhm et al. 2023) due to their behaviour in purchasing, using and discarding products (EEA 2022). Unlike other stakeholders in product

value chains, such as manufacturers, distributors or recyclers, who are relatively predictable because they are strongly driven by monetary rewards and legislative requirements, consumer behaviour is more difficult to anticipate (Shevchenko et al. 2023). The habits and decisions of individuals are embedded in interconnected contexts, including infrastructure, costs, societal norms, and collective and individual values (UNEP 2020a).

Enhancing the capacity of individuals and households to use and preserve objects is relevant but insufficient, as it strips products out of their broader consumption context (Rinkinen and Shove, 2023). Where circular economy efforts are centred on the characteristics and life cycles of consumer goods, questions about the constitution of demand and likely longer-term trends risk being overlooked (Rinkinen, Shove and Marsden 2020). Consumer goods and other objects do not exist in isolation but are part of a broader material culture within a society (Rinkinen, Jalas, and Shove 2015). The meaning and role of objects are interwoven with their social and cultural valuation (Appadurai 1986). Patterns of consumption are rooted in social practices which in turn reproduce these practices of routinized behaviour (Warde 2005; Schatzki 2019). Social practices are a result of how materials and physical infrastructures link with non-material elements such as mental activities, social relations, states of emotion, understanding, know-how, and motivational knowledge (Haberl et al. 2021). Materials, meaning, and competence have been identified as three main types of elements here (Watson and Pantzar 2012), and social change will depend on their linkage in the given context. Cultural intermediaries like advertisers are crucial to shaping perceptions and aspirations beyond the material value of products and services (Kennedy and Givens 2019; Frig and Jaakkola 2023).

Opportunities for citizen participation and civic engagement at the local level can result in enhanced resource efficiency, increased transparency and community engagement promoting sustainable practices such as recycling and energy conservation (Belleville and Miller 2020). Grass-roots community initiatives empower citizens to change systems and strengthen local knowledge and the practices of Indigenous Peoples. Examples of existing collective circular initiatives by citizens include local repair cafés (Charter 2020; Moalem and Mosgaard 2021b), peer-to-peer swap and sharing initiatives (Henry et al. 2021), recycling social enterprises, and community composting (Marchesi and Tweed 2021). Some of these are oriented around social and solidarity economies that prioritize well-being and equity (Villalba-Eguiluz et al. 2023). These community initiatives can function as living laboratories to enable circularity at the local level and create groups of interest that can collectively overcome the constraints that individuals face (Hobson 2020).

Making products and resources circular is not necessarily equivalent to achieving lower material footprints as it can cause rebound effects (Zink and Geyer 2017; Ottelin, Cetinay and Behrens 2020). Material circularity, as such, does not offset the growing demand for goods and services driven by population growth and affluent lifestyles; consumers might even be inspired to buy more if they know there is a viable refurbishment or recycling route (Bocken, Niessen, and Short, 2022). Refurbishment, repair, take-back schemes and digital tools all have their own energy and resource needs. A truly transformative circular economy movement must counteract consumerism and prioritize the quality of life and social well-being by aiming to meet the need for a comfortable life while not needlessly striving to satisfy infinite human material wants (Niessen and Bocken 2021). Sufficiency, also referred to as living-well-on-less (Figge, Young and Barkemeyer 2014) or self-restraint consumption (Figge and Thorpe 2023), is a multi-dimensional challenge that comprises changes in societal values, attitudes, decisions and behavioural routines in everyday practices (Spangenberg and Lorek 2019). For example, if squandering resources became as socially stigmatized as cigarette smoking, less resource-intensive ways of signalling status would emerge (Spangenberg and Lorek 2019). A growing body of evidence suggests that high levels of human well-being can be achieved with lower resource use. Research shows that well-being gains saturate with rising energy and resource consumption (Steinberger and Roberts 2010). It is necessary to utilize well-being indicators to link the transition to circularity with societal transformation (Schröder, Lemille, and Desmond 2020; Velenturf and Purnell 2021).

The actions that follow will help ingrain the circular economy as an aspirational model for societies. They address circularity literacy (Actions 1, 2), infrastructures and materials to support circular behaviour (Actions 3, 4), the shaping of cultural values and social norms (Actions 5–8), and citizen empowerment (Actions 9).

Credit: JuiceFlair/Envato

Action 1: Integrate CE principles into educational curricula from primary schools through to tertiary institutions

Culturally appropriate education and awareness-raising play a crucial role in promoting sustainable practices. Historically, education has contributed to perpetuating the linear economy, promoting industrialization and consumption-driven lifestyles without sufficient consideration for environmental preservation (Jackson, 2009). A transition to a circular economy requires a fundamental shift in mindset and social practices, which can be achieved through education at different levels. Ministries of Education need to integrate circular economy principles into the educational curricula from primary schools through to tertiary institutions, and specialized teaching staff is needed. Funds for schools to implement circular economy activities support success, and the involvement of third parties, including parents, contributes to mainstreaming practices into the broader society and across generations. Circular economy education should be incorporated across disciplines, including economics, engineering and environmental sciences, as a way of preparing and equipping professions to work within the circular economy framework. Municipalities, non-governmental organizations and customary organizations of Indigenous Peoples and local communities can set up initiatives to enhance citizens' circular economy knowledge and public awareness by organizing collective workshops and providing culturally appropriate education materials (Scalabrino, Navarrete Salvador and Oliva Martínez 2022). Data from circularity monitoring is also required to inform citizens about the status of the shift towards a circular economy in their country, as well as specific topics (UNEP 2024b).

Action 2: Training and skills development for workers and citizens to create, use, maintain and repair circular products

More than one third of citizens in the European Union have never used repair services, and most have not rented, leased, or purchased second-hand products (European Commission et al., 2018). This reflects a broader global trend prevalent in consumer-driven economies. Reasons include not only a lack of information but also a lack of competency and specialist skills, inadequate infrastructure such as repair service points, and insufficiently developed markets for second-hand products or sharing services.

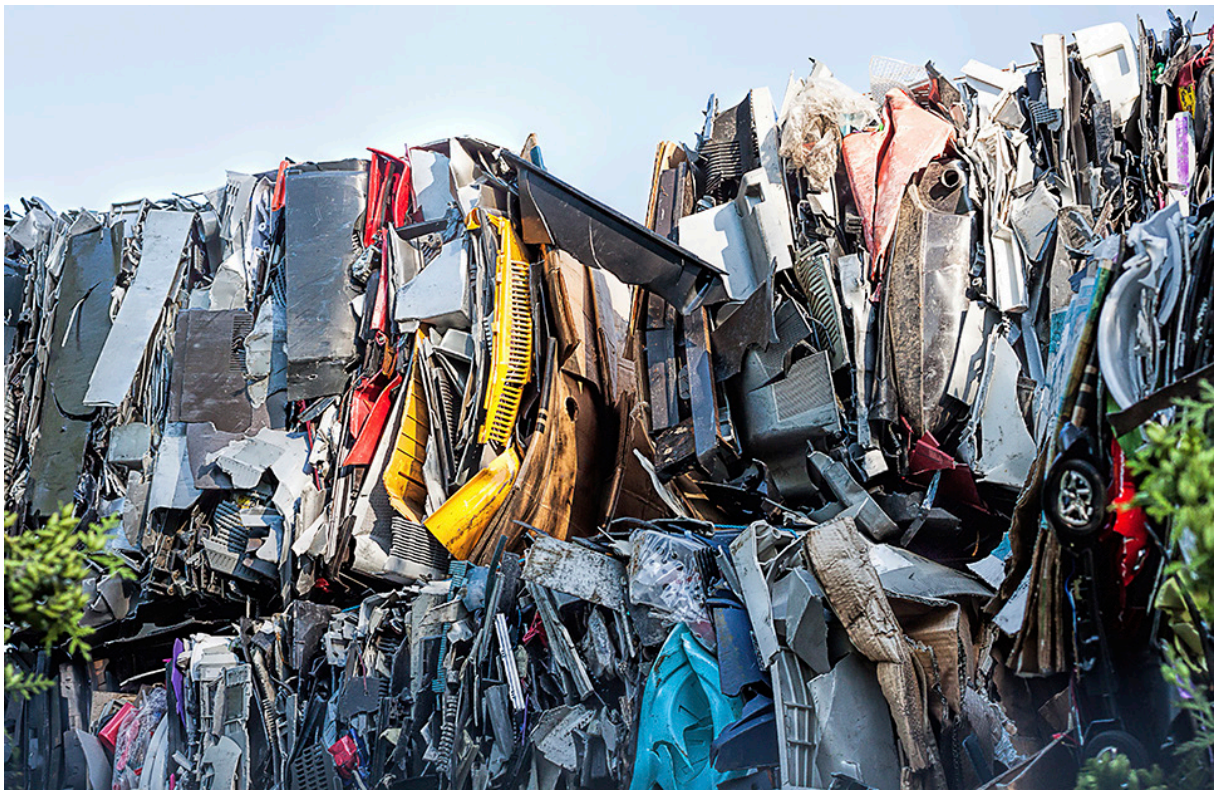
Chambers of commerce, professional networks, and ministries of small and medium-sized enterprises could set up training and certification programmes which can be linked to the development of entrepreneurial skills. Civil society initiatives also play a role in skills development, such as citizen-led repair cafés to promote community repair and, as a co-benefit, provide citizens with a voice in preventing waste and combating environmental degradation. The repair café movement has spread worldwide, with over 2,000 repair cafés now in 37 countries (Moalem and Mosgaard 2021a). The availability of spare parts at reasonable cost and product designs that offer repairability are key enablers to strengthen this movement further.

Action 3: Put in place enabling infrastructures for circular behaviour

Unlike the linear economy, where there is little consideration for how a product is used once purchased, the circular economy needs to factor in consumer behaviour along the product life cycle (Wastling, Charnley and Moreno 2018). Infrastructures integrate social, technical, economic and ecological systems and are key to shaping material flows, including those that influence daily life patterns (Nogueira et al., 2020). At a macro level, product take-back schemes enable circular behaviour, and public-private partnerships can leverage company financing and logistics. Experiences from the Japanese Sound Material-Cycle Society's efforts suggest local governments hold a key position in supporting pro-circular behaviour (Ministry of the Environment Japan 2014). For a successful transition at the local level, local governments can strengthen their capacity with trained professionals and adequate financial resources. Local governments also need to collaborate effectively with citizens and ensure easy and reliable access to repair, reuse or refill schemes, as well as sharing services and composting (Cohen and Kietzmann 2014; Kireeva et al. 2021). To explore infrastructural gaps and effectively co-create solutions, a quadruple helix approach (Hysa et al. 2020; Roman et al. 2020) is instrumental in bringing together civil society, local governments, businesses and the knowledge sector. Municipalities, Indigenous Peoples, local communities, women, youth or civil society organizations can lead these initiatives.

Action 4: Use digital technologies to provide life-cycle product information to consumers in easy-to-understand ways

Digital technologies can help validate the sustainability claims of products and shift consumer behaviour into a circular one (Sánchez-García et al. 2024). Governmental bodies such as ministries of industry can foster the development of digital product information and labels in an easy-to-understand way that is comfortably accessible for citizens, such as using QR codes. Independent third-party certification bodies need to ensure the transparency and accuracy of information to avoid greenwashing.



Action 5: Foster societal-wide dialogues on alternative social practices, culture and lifestyles, and support social innovation at the community level

For widespread societal embedding, including in multicultural areas, circular economy practices need to find their place in daily life among the manifold practices that compete for individuals' time and resources (Huber 2017). Engaging citizens in dialogues about lifestyles can be initiated both by civil society and the public sector to raise awareness and promote mindfulness about consumption patterns. This will play a crucial role in shaping cultural norms and values, as a collective shift would likely create a milieu that fosters circular principles (Kasser and Gonick 2018). Ultimately, this fosters policies and governance structures that shift from consumerism towards circularity.

Simultaneously, supporting social innovation – whether through financial incentives, policy support or knowledge-sharing – empowers citizens to have agency and influence when engaging in local collective action (Hoppe and Warbroek, 2021) and mobilizes society's creativity. These support measures are necessary for both start-ups and existing initiatives, including those that support Indigenous Peoples and local communities, as well as women and youth. Indigenous cultural and community-centred values, traditions such as resource sharing, and practices such as caring for nature offer lessons on how collective values and collaboration can support sustainability (Brondízio et al. 2021; Greene, Hobson and Jaeger-Erben 2024).

Action 6: Promote traditional practices and Indigenous Knowledge on lifestyles for well-being and sustainability

Indigenous sociobiocultural systems are rich in circular practices and innovations (Case Study 2). Understanding and integrating their principles, including the significant contributions of women, can strengthen the social, economic, customary and cultural pillars of a modern

Credit: ©UNEP

circular economy and promote the pursuit of well-being. The customary governance system, collective ownership and biocultural self-determination with participatory decision-making processes of Indigenous Peoples are important elements (Rai 2018). Indigenous Peoples are mostly collective, cosmologic, traditional and are more likely to consider the present and future impacts that their actions have on others and the environment, rather than focusing on immediate self-gratification or rewards. Practices that align with modern societies are more likely to be taken up across the broader non-Indigenous population. Such practices can be effectively promoted by non-governmental organizations, Indigenous institutions and academic entities.

Action 7: Develop communication strategies and campaigns that promote behaviour change, engage with cultural intermediaries and restrict advertising of linear products

A negative perception of a circular good or service, such as perceiving repaired products as lower quality or less fashionable, is a key barrier to the adoption of pro-circular practices (Houston et al. 2018). Looking at a product with some degree of favour or disfavour is a learned attitude, while perceptions express a person's beliefs about a product's characteristics (Muranko et al. 2019). These represent changeable evaluations and can be shaped through science-backed campaigns initiated by public bodies or non-governmental organizations to ensure credibility and effectiveness. Cultural intermediaries, such as advertisers and influencers, influence consumer perceptions of goods and practices that appear aspirational, and they are well-positioned to promote sustainable consumption choices among different societal groups.

Advertising exerts a profound influence on consumers' preferences for specific products and lifestyles (Vaughn 2000). Curbing the demand for environmentally detrimental products fosters a culture of sustainable consumption. Advertisements for linear products can be banned or organized in a way that communicates their harmful effects to consumers, for example, through successful laws against the advertisement of cigarettes (Kasza et al., 2011). Restricting advertising for high-impact linear product categories reduces the allure of these unsustainable choices and encourages producers to seek circular options in their processes as a way of leading the competition. Effective measures include legislative regulations related to advertising and for national advertising standards agencies to oversee the implementation. An internationally agreed list of harmful linear product categories would facilitate this action.

Action 8: Include circularity metrics and human well-being indicators into socioeconomic planning and participatory decision-making

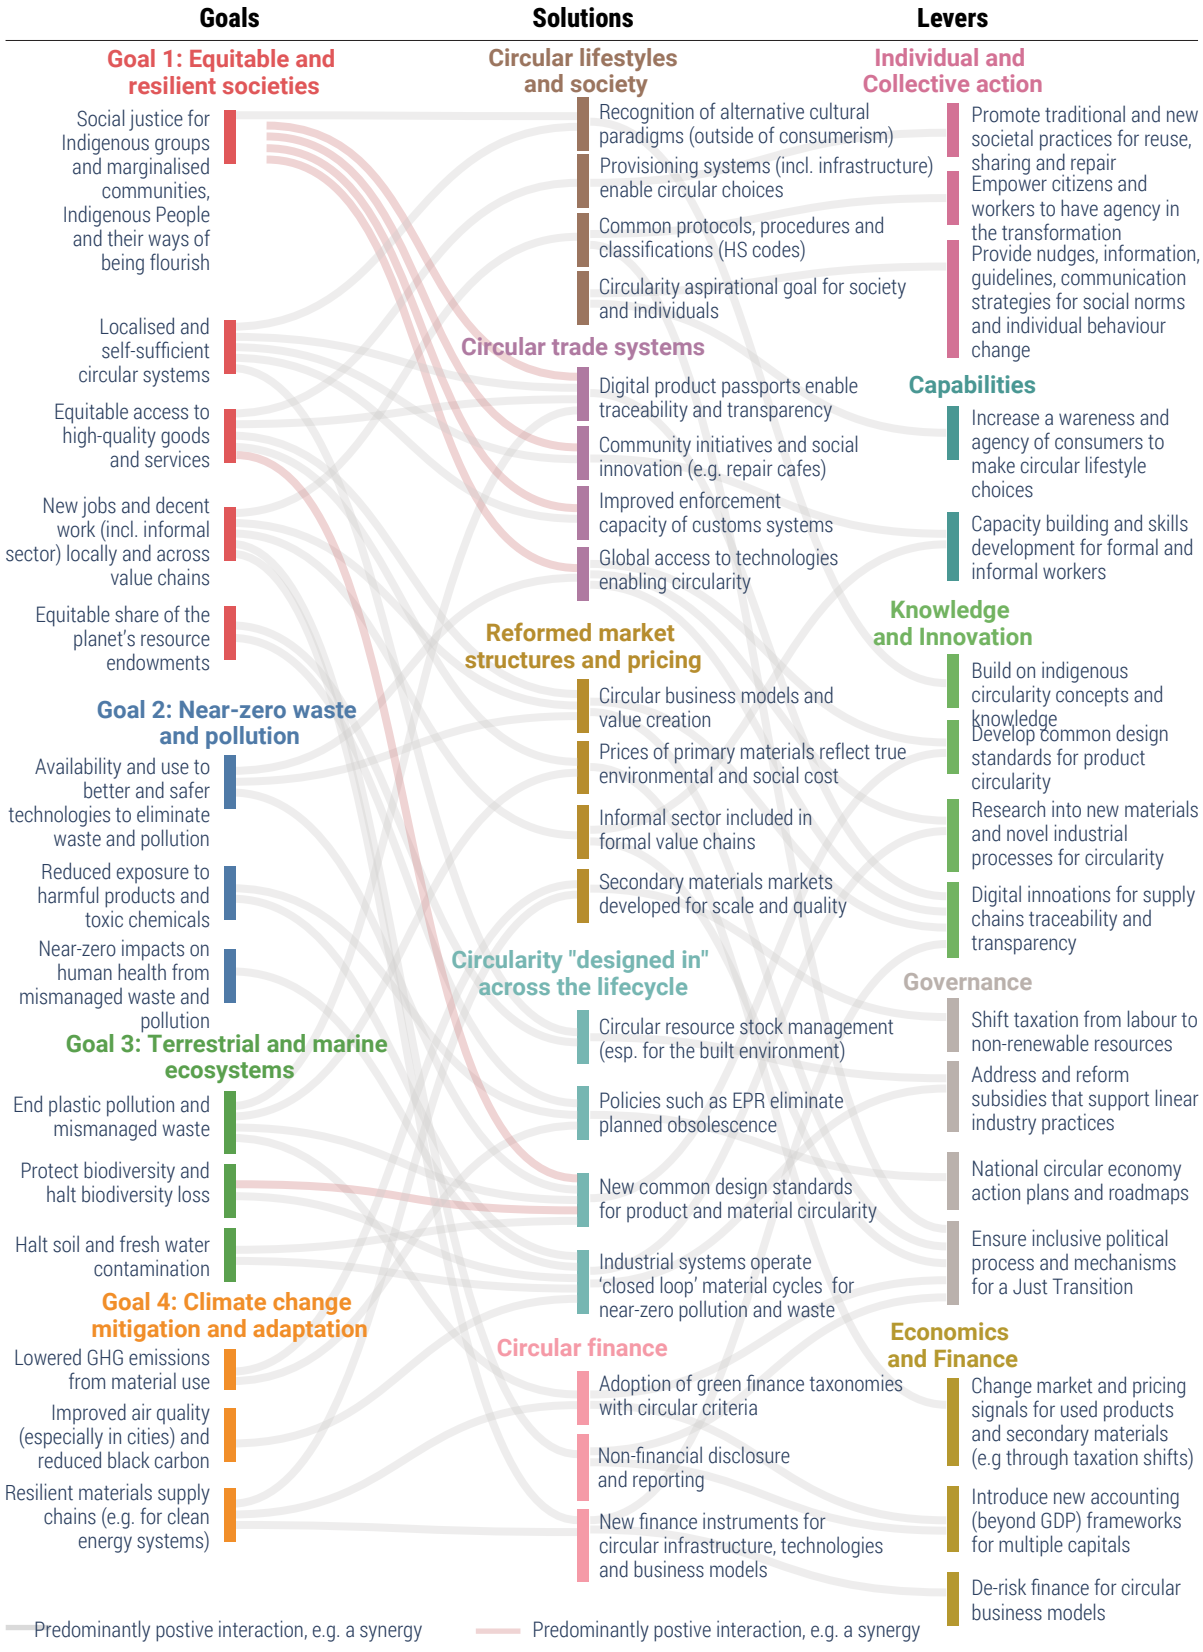
Comprehensive circularity metrics and sound data are essential to support policy designs and decision-making and to inform citizens about the status of the shift towards the circular economy. Many varied indices and frameworks are used to capture circularity, with partially contradictory results (Corona et al. 2019). Efforts to consolidate approaches and make them policy-relevant are ongoing (UNEP, 2024b) and warrant a significant effort. Circularity metrics based solely on the degree of material recirculation are easier to apply and may play a significant role in increasing public awareness; however, they are not suitable for measuring the absolute decrease in resource use and do not accurately reflect sustainability (Corona et al. 2019). Currently, there is no comprehensive framework to assess the positive or negative social effects of circular economy strategies (Padilla-Rivera et al. 2021) and whether the shift to a circular economy is actually improving people's lives and well-being. More clarity is required on how to effectively integrate such indicators in social, economic and cultural planning, both at national and local levels. The well-being of vulnerable groups, including people with disabilities, must also be taken into account.

Action 9: Reward individuals for their active participation and engagement as consumers, citizens, workers, carers and community members

Consumer studies and behavioural research have shown that individuals are generally willing to engage in circular practices, such as repair, sharing and buying second-hand; however, in practice, the numbers are comparatively low (Trinomics 2018; Hobson 2020). Rewarding individuals for their active engagement increases their commitment and motivation (Korsunova, Horn and Vainio 2021), and both monetary and non-monetary reward schemes can be set up by local governments or civil society initiatives. An example is the Repair Bonus Policy introduced in Austria in 2023, where 50 per cent of the repair costs of electronics are covered by the Government's COVID Recovery Fund (Hoppe and Warbroek 2021; Bell 2023; Edler, Ostertag and Schuler 2023).

15.2.6 Combinations of solutions to achieve desired goals

The transformation from a linear to a circular economy involves implementing a range of subsystem level solutions and integrating various pathways to drive comprehensive system-wide change. This requires breaking down silos and fostering synergy between actions and approaches to achieve full system transformation, aligning with the four goals outlined in Section 15.1.2.



Based on the assessments of the experts involved in the GEO-7 process, the enabling conditions for this include, but are not limited to, a mutually reinforcing combination of cross-cutting levers and actions as follows:

1. setting prices to reflect full costs while mitigating impacts on low-income groups
2. using digital technologies such as digital product and material passports to enable traceability and data to establish and monitor full cost pricing
3. co-designing and implementing extended producer responsibility policies
4. harmonizing eco-design standards that assist intelligent assembly and disassembly of products, components and materials
5. de-risking investments in infrastructure, which supports reverse logistics and small businesses and local economies
6. promoting the rapid uptake and diffusion of technologies enabling circularity, especially for developing countries
7. building capacity of workers in informal sectors to reduce exposure to hazardous materials
8. empowering citizens and workers to have agency in the transition enables emergence of bottom-up solutions and local job creation
9. recognizing Indigenous rights and building on Indigenous circular knowledge systems will directly benefit communities and human beings

Cross-cutting solutions, such as international coordination on national circular economy action plans, trade agreements and capacity-building initiatives, ensure that the transition to a circular economy supports global development objectives and the Sustainable Development Goals. Additionally, including Indigenous Peoples, women, youth, and persons with disabilities in decision-making processes helps to foster

social justice and resilience, ensuring that circular systems benefit all. These levers and policy arenas reinforce each other and contribute to the four goals. Mixed interactions and potential trade-offs exist between actions that promote global circular trade and those that create localized circular economic systems. **Figure 15.7** provides more detail.

Figure 15.7: Simplified overview of interactions between levers, solutions and goals of the circular economy solution pathways and actions

15.3 Solutions case studies

The following two case studies were selected to highlight diverse approaches to the circular economy. China, as the world's second-largest economy, has a structured industrial circular economy policy, offering insights into large-scale implementation (**Box 15.1**).In contrast, the Indigenous case study showcases nature-based solutions, emphasizing regenerative practices (**Box 15.2**). While the circular economy spans many sectors and geographies, these examples illustrate both high-level industrial policyframeworks and community-driven models based on Indigenous Knowledge.

Box 15.1: Waste management and the zero-waste cities programme in China

China is not only the world's largest producer and consumer of electronics but also the most seriously polluted by illegal e-waste imports and informal recycling in the 1990s (Li et al. 2015). Historically, most e-waste was diverted into informal recycling channels, making it economically unviable for many formal companies to sustain operations based on the limited volumes they were able to collect and process. The efficiency and viability of formal recycling are subject to various national legislations, technical capacity and actual throughput, and consumer participation. The EPR principle is integrated through the old-for-new policy and the e-waste producer-pays funding (Zeng et al. 2017). Financial incentives are crucial to enable the flow of waste to the formal routes successfully.

The technical recycling process is crucial in achieving a high material recycling rate. After a two-decade journey, China has established more than 100 licensed companies engaged in high-quality e-waste dismantling and recycling lines for waste printed- circuit boards, liquid crystal displays, toner cartridges, computers and refrigerators. Substituting materials in electronics and reducing toxicity through green design and environmentally sound disposal are among the most impactful strategies for enhancing the recovery of secondary resources from e-waste. Enhancing eco-design and promoting design for recycling can be enabled through altering materials and components, developing longer-life and more durable equipment, and taking responsibility for safe recycling pathways. Formal recycling facilities are now available throughout the country, and informal e-waste recycling is shrinking. The national e-waste recycling rate in 2020 reached 40–50 per cent (Sun et al. 2022). Overall, the idea of "Control-Alt-Delete" (Li et al. 2015), which targets the combined effect of controlling waste flows, altering the characteristics of electronics, and deleting e-waste-related toxicity, has proved successful.

China also launched a Zero-waste City pilot programme in 2019, and this initiative expanded to more than 100 cities in 2022. The goal is to establish a sound circularity system to achieve fully environmentally sustainable cities by 2050. Under the Government's green development plan, the country has made significant progress in minimizing solid waste generation and maximizing waste recycling in urban areas. Since 2021, China has promulgated the Work Plan for Zero-waste Cities in the Fourteenth Five-Year Plan, which identifies 113 cities and 8 special zones as zero-waste cities. The Zero-waste City programme is considered one of the world's largest long-term recycling initiative, as well as the most extensive city-improvement programme (Lee et al. 2020).

Box 15.2: Circular practices used by Indigenous Peoples and traditional or local communities

Many circular practices exist in traditional and Indigenous communities and predate modern technologically oriented iterations of the circular economy. Indigenous practices – whether in building materials, such as Maasai huts made from natural resources and waste or resource-sharing systems – emphasize regeneration by ensuring cyclical use of resources without depleting ecosystems. Components of Indigenous socio-biocultural systems share principles that prioritize healthy socioeconomic, moral, ritual, spiritual, epistemological, lingual, sentimental, ethical, and ecological biocultural and customary relationships with "Mother Nature" and "Mother Earth", supported by appropriate ecological regeneration. These principles can inform a modern circular economy for the protection of biodiversity, lands, waters, territories of Indigenous Peoples, food, health systems and human well-being. Examples of Indigenous embedded relationships with natural systems can provide insights in understanding and informing circular economy transitions today. For instance, in the case of Hawaii, the concepts and practices meant by certain words – such as aloha for acknowledgement, āina for love of the land, and Ōiwi for native or durable values – can be taken as interventions that address the underdeveloped social and cultural pillars of the circular economy. Indigenous approaches to sustainability promote regenerative relationships, for example, the ancestral Hawaiian economic system that mirrored the natural structures of the water cycle (Beamer et al. 2023).

Credit: ©UNEP

Indigenous principles encompass a profound sense of unity and interconnectedness between nature and humans and emphasize the importance of giving back to nature. Indigenous practices, such as shifting cultivation and the rotation of cultivated plots of land – used to manage tropical forests in many regions of the world, including Africa, South and Southeast Asia, the Amazon and New Guinea – facilitate the natural regeneration of soils and vegetation (Mazzocchi 2020). In the Western Ghats of southern India, the traditional collection and production of non-timber forest products, such as wild species, honey, amla, soap, nuts and berries, are helping to ensure the management of forest resources in the reserve while sustaining the livelihoods of Indigenous communities (Craigen 2021).

In Asia, the Nepal Indigenism Mondhum Biocultural for Restoration and Biodiversity Conservation Initiative on Landscapes promotes customary governance and circular approaches to agroecology (Rai, 2023), aligning with the Kunming-Montreal Global Biodiversity Framework's Indigenous and traditional territories Target 3 in the National Biodiversity Strategy and Action Plan. Indigenous communities' resource and biobased material flows are mostly local or regional and organized in circular and regenerative patterns.

All ecological communities are defined and maintained through the cyclical exchange of resources among members, establishing collaborative relationships that encourage diversity and facilitate the sharing of abundance, maintaining systemic health (De Nardin 2022). Furthermore, Indigenous concepts and philosophies such as the African Ubuntu can provide alternative frameworks to address common global problems caused by linear extractive economies and their effects, such as climate change and environmental degradation (Van Niekerk 2022; Fernández 2022).

Ancestral multidimensional visions of circularity have guided many Indigenous Peoples' lifeways, values, spirituality, community structures and vernacular architecture. Maasai communities on the border of Kenya and the United Republic of Tanzania have lived off-grid for centuries and are one of the best examples of communities with circular ways of life. Traditional Maasai are semi-nomadic pastoralists who range cattle in the Dry Lands looking for fresh grazing. Maasai do not hunt or fish; they are deeply connected with their cattle herds and the arid or semi-arid landscapes, which provided for most of their needs before their traditional lifeways were disrupted by colonialism and climate change (Marty et al. 2023). Maasai living in rural areas use cattle dung as fuel, fertilizer and as a building material for their homes. A mixture of cow dung, urine, and natural materials is used to build their circular huts, known as manyatta. The dung plaster keeps the inside of the huts cool. More recently, waste plastic bottles have been used to reinforce the structures and offer additional rain protection (Kamweru 2023). Maasai bomas or villages are circular arrangements of manyatta huts around a central corral where cattle are kept and manure is stored. The circular arrangement of the huts fosters community-centred values of equality, and the bomas radiate outwards as families grow. The surrounding solid fences, made of thorny acacia tree branches, protect families and livestock from wildlife (Rukwaro and Mukono 2001).

Indigenous practices, such as traditional building design, can help restore degraded relationships between humans and nature. These ancestral frameworks highlight the importance of embedding reciprocity and restoration into economic systems, providing scalable models for modern regenerative development. However, the traditional way of life of the Maasai and many other Indigenous Peoples is increasingly under threat and will require active support to sustain and strengthen these practices within a modern circular economy framework.

15.4 Synergies and trade-off interactions with other systems

Energy system:

As highlighted by the Secretary-General's Panel on Critical Energy Transition Minerals (United Nations, 2024), the transition to a low-carbon energy system will require circular economy practices to avoid significant increases in extractive activities and waste generation, as well as a shortage of critical energy transition minerals. End-of-life solar photovoltaic panels, wind turbine blades, and electric vehicle batteries will become high-volume waste streams within the next two decades, and effective collection and recycling schemes and material valorization infrastructures are largely missing. Worldwide annual solar photovoltaic waste generation is estimated to increase from 0.3 million to 9.6 million tons between 2016 and 2050 (Chowdhury et al. 2020), and is projected to accumulate to between 60 million and 78 million tons by 2050 in the absence of recycling (Divya et al. 2023). Far greater advances are needed in the design of materials for disassembly and recyclability. For example, the carbon/glass-fibre-reinforced composite materials used in current wind turbine blades hinder any economically viable recycling (Khalid et al., 2023). End-of-life electric vehicle batteries present their own unique challenges, including the risk of fires in conventional e-waste recycling facilities, the rapid evolution of material compositions for new battery technologies, and highly variable market prices for recycled materials (Harper et al. 2019; Tembo, Dyer, and Subramanian 2024). Synergies with renewable energy deployment can be unlocked by repurposing electric vehicle batteries for stationary energy storage (Jaimes and Maroufi, 2020; Colarullo and Thakur,

2022). A decarbonized energy system and the circular economy have a critical synergistic potential through hydrogen because hydrogen availability and CO_2 valorization are intrinsically interlinked (Do et al. 2022). A wide variety of other circular economy technologies support energy security, such as the energetic valorization of residual plant biomass. For some, the full potential remains to be explored, including the generation of hydrogen from waste (Aziz, Darmawan, and Juangsa, 2021).

Food system:

Several circular solutions support food system transformation, including Indigenous food systems (Forest Peoples Programme 2016; Levkoe, Ray and McLaughlin 2019), food waste reduction (Vittuari et al. 2023), valorization for biofertilizers or upcycling into high-value biochemicals (Said et al. 2023; Patel et al. 2024; Aït-Kaddour et al. 2024), which enables nutrient cycling and the restoration of soil health (Villamagna, Angermeier and Bennett 2013; Palansooriya et al. 2023). Technologies such as black soldier fly bioconverters, which produce animal feed, support food security and the incomes of smallholder farmers (Mlambo et al. 2023). Regenerative agricultural practices and the repurposing of urban spaces for community agriculture are integral to the transition to a circular economy. The combinations of circular practices can also promote and revitalize Indigenous food and agricultural systems and customary practices.

Environment system:

The circular economy as an ecological transformation of the economic system promises both human well-being and the regeneration of environmental system (Jabbour et al. 2020; Yang et al. 2023). The circular economy in combination with a sustainable bioeconomy (Chapter 18) can benefit biodiversity and ecosystem health through three key mechanisms: the reduction of extraction and primary resource use, prevention of pollution by eliminating waste and use of hazardous substances and biodiversity-friendly sourcing of resources (Ellen MacArthur Foundation 2021a; Günther et al. 2023). The use of biobased materials as substitutes (Asgher et al. 2020) includes seaweed farming, which serves as a regenerative aquaculture practice that not only provides a sustainable source of food and biobased materials but also delivers nature-positive outcomes by enhancing marine biodiversity and improving water quality (White 2023). Furthermore, regenerative design approaches in the built environment can create nature-positive outcomes for environmental system.

However, reducing natural resource extraction is vital (UNEP 2024a). The efficiency of natural resource utilization, along with ecosystem restoration and regeneration, can be enhanced by implementing a circular bioeconomy (Abad-Segura et al. 2021). There are risks, however, that the shift to biobased resources creates additional pressures on the environmental system. The effects of the circular economy on biodiversity are still not well understood and are particularly challenging to assess (Ruokamo et al. 2023). The uptake of biomass to replace mineral resources is part of the circular economy, but this might imply deforestation and biodiversity decline, and the water needed for additional biomass growth could exceed sustainable supply levels (Giampietro and Funtowicz 2020). Among others, the circular bioeconomy utilizes biological processes to recover valuable materials, such as rare earth elements, from industrial and electronic waste through biomining (Opare, Struhs, and Mirkouei, 2021). Circular bioeconomy solutions, such as biogas generation from organic residues, are already widely adopted technologies to supply electricity, heat or other forms of energy. The circular bioeconomy also supports ecosystem health by making the best possible use of each unit of the conditionally renewable resource biomass, for example, through a cascading use of biological resources.

Chapter summary

Credit: mypics/Envato

Identifying and leveraging synergies between the energy transition and other systems can accelerate change by achieving multiple policy goals and improving cost-effectiveness *(very well established)*. The costs of inaction are higher than the costs of mitigation for pathways that limit global warming to 2°C over pre-industrial levels by the end of the century. While the current Nationally Determined Contributions fall short of meeting the Paris Agreement temperature target, aligning climate action with the Sustainable Development Goals (SDGs) can provide substantial co-benefits. For example, climate mitigation policies that also reduce air pollution could limit global warming levels by 0.5°C and save 2.4 million lives annually {16.2.3; 16.3; 16.5}.

Equitably sharing costs and benefits of the energy transition can build political and public support for climate and renewable energy policies, among others *(very well established)*. Combining subsidies for lower-income groups with training and capacity-building can address shifts in employment and livelihoods and improve distributional outcomes in national and subnational energy and climate policies. Actions, including access to and availability of finance, that recognize historical and current inequities and injustices between countries can enhance international cooperation *(well established)*. Equitable benefit-sharing together with participatory and inclusive decision-making for disadvantaged and marginalized groups, including Indigenous Peoples, can help prevent new energy developments from perpetuating harms and injustices *(well established)* {16.2.1; 16.2.2; 16.3; Box 16.1}.

Reforming economic incentives and phasing out subsidies for fossil-fuel production and consumption can improve the competitiveness of decarbonization efforts *(well established)*. Globally, fossil-fuel subsidies are estimated at 7 trillion (2022 US$) or 7.1 per cent of GDP. While politically challenging, subsidy reform could reduce emissions by approximately 36 per cent by 2025, prevent nearly one million premature deaths annually through improved air quality and generate substantial fiscal revenues. Carbon pricing mechanisms, carbon markets, taxing, and the application of the social cost of carbon can further support decarbonization efforts {16.2.3; 16.3}.

Closing the energy poverty gap requires coverage and access to modern and affordable electricity and clean cooking fuels at the household and community levels *(very well established)*. Achieving SDG 7.1, which aims

for universal energy access for all by 2030, is estimated to cost US$45 billion annually, representing less than 2 per cent of overall clean energy spending. Universal energy access supports multiple SDGs by improving basic services and infrastructure, health, education, and livelihood opportunities. Stand-alone systems, as well as mini and microgrids, can provide reliable and adequate electricity where grid expansion is not feasible. Including social and cultural considerations improves the adoption of clean electricity and modern fuels *(well established)* {16.2.1}.

Leveraging public finance to de-risk investment and reduce the cost of capital can mobilize private investment and support the energy transition in lower- and middle-income countries *(well established)*. Targeted subsidies and concessional financing can facilitate universal energy access, particularly to the lower-income countries and among Indigenous Peoples. Guarantee agencies have proven to be effective in attracting private investments in these countries *(established)*. Development banks can act as intermediaries between financial markets and borrowers, helping to reduce real and perceived risks, lower capital costs, and enhance financial flows and investment. *(well established)* {16.2.1; 16.3.3}.

Improving energy efficiency through higher-efficiency appliances, compact urban development, and public and active transportation can reduce energy demand, while delivering health and environmental co-benefits *(very well established)*. Stricter minimum energy performance standards, retrofit programmes, and passive building designs, implemented by local and national governments, lower energy use in buildings. Heat pumps for space and water heating can further reduce energy consumption, and their installations can be supported through subsidies and regulations *(virtually certain)*. Policies and funding mechanisms that promote mixed land-use support public and active transport, avoid long-term carbon lock-in, and improve human well-being *(well established)*. Prioritizing low-income populations, including those in informal settlements or with disabilities, can ensure equitable access to lower energy-efficient options *(established)* {16.2.2; 16.4.1}.

Promoting behavioural change and collective action can reduce energy demand and help address inequality *(well established)*. Programmes can target various behaviours, including turning off equipment and recycling, as well as energy labelling, which can lower building energy demand by 5-30 per cent, depending on the building type and region. Renewable energy communities, in both urban and rural settings, can foster local ownership and align with user priorities. Social movements advocating for climate and energy justice, including those led by youth, Indigenous Peoples, women, labour, non-governmental organizations, and civil society, also play a crucial role in driving change {16.2.1; 16.2.2; 16.4.2}.

Limiting global warming to 1.5 °C by the end of the century requires a rapid decarbonization of the energy system, with 74–82 per cent of primary energy coming from low- or zero-carbon sources by 2050 *(very well established)*. By the middle of this century, 97–99 per cent of global electricity demand needs to be met by low- and zero-carbon sources. Replacing fossil fuels in hard-to-abate sectors requires developing markets for advanced biofuels, green hydrogen, green ammonia, and green methane *(well established)*. Electrifying energy-intensive sectors, such as transportation and industry, combined with clean electricity generation, is key to driving energy system decarbonization. Investment in grid infrastructure needs to at least double to around US$600 billion annually by 2030, to stay on track for the net-zero emissions by 2050 *(well established)* {16.2.3}.

Atmospheric carbon dioxide removal, including bioenergy with carbon capture and storage, is crucial for achieving net-zero carbon dioxide emissions by mid-century and limiting warming to 1.5 °C by the end of the century *(well established)*. Carbon dioxide removal can help offset residual emissions in hard-to-abate sectors. Bioenergy with carbon capture and storage (BECCS) and biochar could generate net energy, unlike direct air capture with carbon capture and storage and enhanced weathering, which require additional energy. However, biomass-based carbon dioxide removal (CDR) options, such as BECCS, face substantial sustainability challenges. Managing the trade-off between various CDR options requires a portfolio approach that accounts for environmental impacts and implications for economic prosperity and well-being {16.2.3}.

Developing new oil and gas fields is incompatible with the goal of limiting the warming to 1.5°C by the end of the century *(very well established)*. Oil and gas demand needs to decline by around 20 per cent by 2030, with

a global reduction in fossil-fuel use of 55-70 per cent by 2050. Expanding renewable energy reduces the need for new fossil-fuel production facilities. Phasing out fossil fuels from energy systems is achievable at a relatively low cost over the next decade *(well established)*. Investing in training and capacity-building is essential to ensure a just transition and prevent economic disruption *(well established)* {162.3; 16.3}.

Improving circularity in critical energy transition metal value chains can help reduce negative environmental and social impacts *(well established)*. The demand for critical energy transition metals is expected to increase fivefold between 2018 and 2050. Strengthening regulations and international coordination is necessary to enhance efficiency, minimize waste, and enhance governance throughout the value chain. Innovation, including the integration of advanced technologies, can enhance trust and traceability. A substantial proportion of critical mineral deposits are situated within or in close proximity to biodiversity hotspots and regions experiencing water stress. Where trade-offs arise, such as biodiversity loss and water and land degradation, the use of participatory and rights-based approaches is essential to address inequities, especially for Indigenous Peoples and marginalized groups *(well established)* {16.2; 16.5; Box 16.1}.

Energy sovereignty is essential for ensuring access to clean and affordable energy for Indigenous Peoples, including through demand reduction *(established but incomplete)*. At least 54 per cent of energy transition minerals are located on or near Indigenous Peoples' territories. Therefore, upholding Indigenous Peoples' right to self-determination, guided by the principles of free, prior, and informed consent, must be respected to ensure equitable benefit-sharing from mining and land use. Policies that respect Indigenous territorial rights and legal orders, support self-management of resources, enable community-led environmental monitoring, protect labour rights, and ensure fair revenue distribution can reduce inequities in the mineral value chain {16.2.4; 16.3}.

Sustainable and just energy transitions can support climate change adaptation and enhance nature and biodiversity *(well established)*. Indigenous Peoples and local communities play a crucial role in biodiversity conservation, but energy projects and infrastructure often threaten biocultural diversity by continued rights violations and environmental injustices to Indigenous Peoples and their territories. Promoting biocultural diversity and Indigenous rights can decrease the damages of energy systems to biodiversity *(established but incomplete)*. Expanding energy access and closing the energy poverty gap increase the resilience of vulnerable populations, for example, by powering early warning systems *(very well established)* {Box 16.1}.

Breaking down silos between policy domains improves coordination of energy transition and sustainable development *(virtually certain)*. Integrating robust circularity practices in critical energy transition metal value chains can reduce material demand and minimize adverse environmental and social impacts *(well established)*. Innovative energy solutions, such as agrivoltaics, which combine energy production and agriculture, can be effective in reducing energy and land-use challenges *(well established)*. Policies supporting integrated watershed management, including mini and microhydroelectric plants, can boost electricity generation, restore forests and benefit communities *(well established)*. Subsidies, government loans, and research and development are key to advancing emerging technologies *(well established)* {16.3; 16.5}.

16.1 Introduction

Transforming energy systems requires rapid and significant changes in both developed and developing countries to align with the Paris Agreement's long-term temperature goals – limiting global average temperature to well below 2°C and striving to keep it to below 1.5°C above pre-industrial levels - while also supporting the achievement of the the Sustainable Development Goal 7: ensuring access to affordable, reliable, sustainable and modern energy for all.

Of the 620 exajoules of primary energy used worldwide in 2023, 81.5 per cent originated from fossil fuels and 14.6 per cent from renewables. In 2023, renewables accounted for 13.5 per cent of total final energy consumption, a key indicator used to monitor Sustainable Development Goal 7, and are projected to reach 20.9 per cent by 2030 (International Energy Agency [IEA] 2025a). Wind and solar energy contributed 13.25 per cent in 2023 for electricity, with growth rates of 10.3 per cent and 24.2 per cent, respectively, (Energy Institute 2024).

Energy consumption supports the needs of the global population, but generates pollution, with carbon dioxide (CO_2) being the most prevalent greenhouse gas. There is a near-linear relationship between cumulative CO_2 emissions and global warming (Intergovernmental Panel on Climate Change [IPCC] 2021). Given the direct effect of fossil fuel production and consumption on rising global temperatures, it is crucial to rapidly decarbonize the global energy system to align with the targets of the Paris Agreement.

However, nearly 20 per cent of the world's population lives in countries at risk of not achieving a socially responsible energy transition with equitable, just and inclusive outcomes (World Economic Forum [WEF] 2024). Nationally determined contributions are not on track to meet the Paris Agreement temperature goals.

Emission reductions across all sectors are estimated to require a 42 per cent cut by 2030 and 57 per cent by 2035 to stay aligned with a 1.5°C target by the end of the century (United Nations Environment Programme [UNEP] 2024a).

To address the challenges outlined above, this chapter identifies four critical solution pathways:

- energy access for all – ensuring that everyone has access to modern, reliable, affordable, and clean energy supplies
- energy-demand management through energy efficiency, land-use planning, and behavioural change
- decarbonization and transition away from fossil fuels, including diversification and decentralization of the grid
- reducing damages in the shift to new technologies by achieving environmental sustainability in the critical energy transition mineral value chain

To enable these pathways, this chapter considers regulatory certainty and expectations of increasing stringency, improved access to finance and governance that balances trade-offs without worsening existing inequities, and alignment with a just transition. Research and development and technological advancements also play a crucial role in reaching these objectives.

The chapter advances the assessment of energy transformation actions highlighted in the IPCC Sixth Assessment Cycle (IPCC 2023a). These include significant reductions in overall fossil-fuel use, minimal reliance on unabated fossil fuels, and the application of point-source carbon capture and storage in remaining fossil-fuel systems. Further transformations such as electricity systems that produce no net CO_2 emissions, widespread electrification, and alternative energy carriers in sectors less suited to electrification are also covered, as well as energy conservation and efficiency.

The chapter also assesses the feasibility of adaptation options, recognizing the dual role of energy as a means for adaptation and the vulnerability of energy infrastructure worldwide. Diversifying energy generation sources such as wind, solar, small-scale hydropower and managing demand through storage and energy efficiency improvements can boost energy reliability and reduce vulnerabilities to climate change.

The energy transition must incorporate infrastructure resilience, particularly to extreme weather events, reliable power systems, and efficient water use for existing and new energy generation systems (IPCC 2022a).

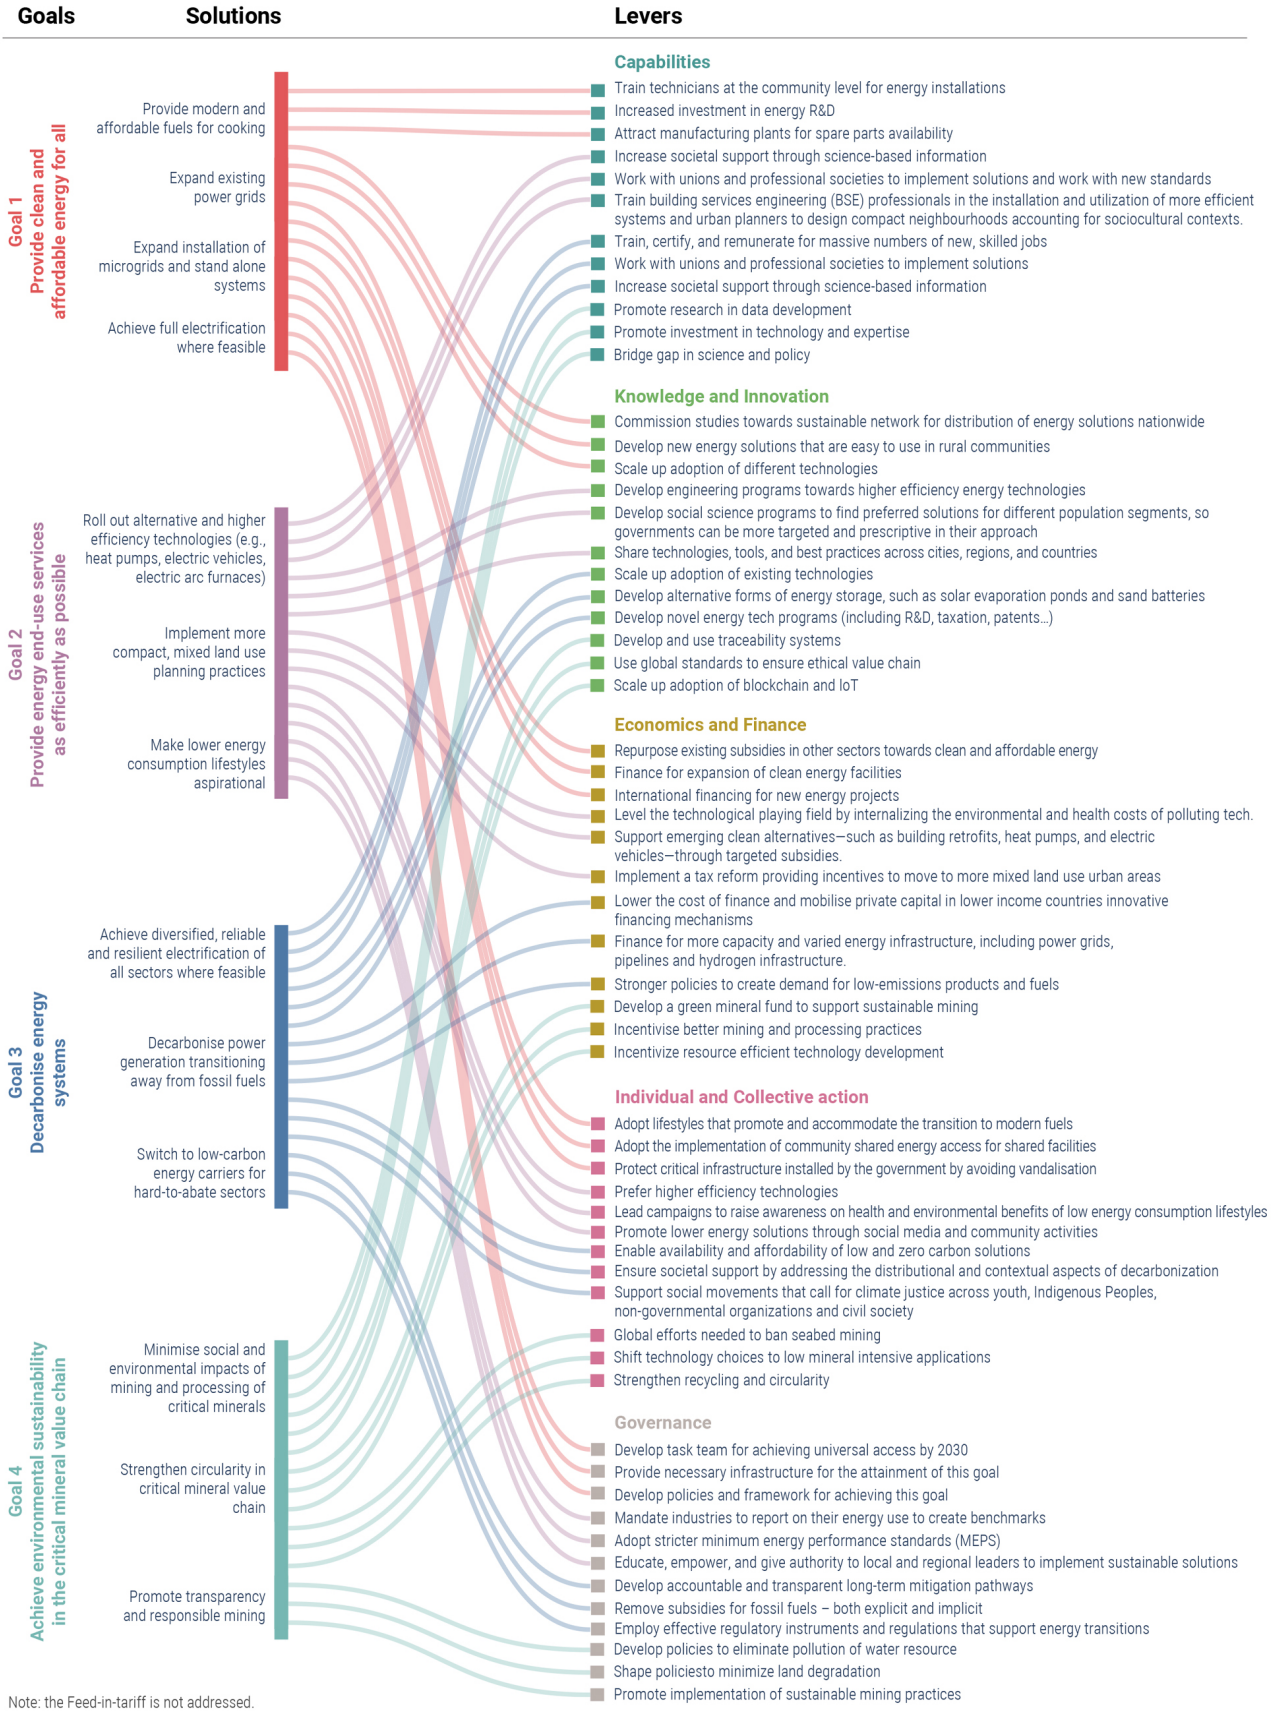
16.2 Solution pathways for energy system transformation

An overarching goal of a transformed energy system is that it is sustainable, affordable, reliable, and equitable, ensuring no one is left behind. While achieving these goals is technically possible and often cost-effective, deploying all these solutions at scale requires overcoming a range of challenges, including geophysical, environmental, economic, technological, sociocultural, and institutional barriers (IPCC 2022b). Political support and international cooperation are key to enabling energy transitions across developed and developing countries. At the same time, subnational governments, private sector entities, civil society, communities, and individuals all play an important role by implementing policies and embracing behavioural changes.

Aligned with the theme of GEO-7 to find solutions for the global environmental crises of climate change, biodiversity loss and land degradation, and pollution, this section focuses on four specific energy system goals. It proposes a variety of solutions and actions to support these goals, suggests specific levers to implement them, and identifies the actors and institutions responsible for their execution (**Figure 16.1**).



16.2.1 Solution pathway 1: Provide environmentally sustainable, safe, reliable, and affordable energy access and clean cooking, and eliminate energy poverty for all

There are three main technological options for bridging the electricity access gap, including stand-alone solar photovoltaic systems, mini-grids or distributed generation systems that utilize various renewable energy sources, and grid extension.

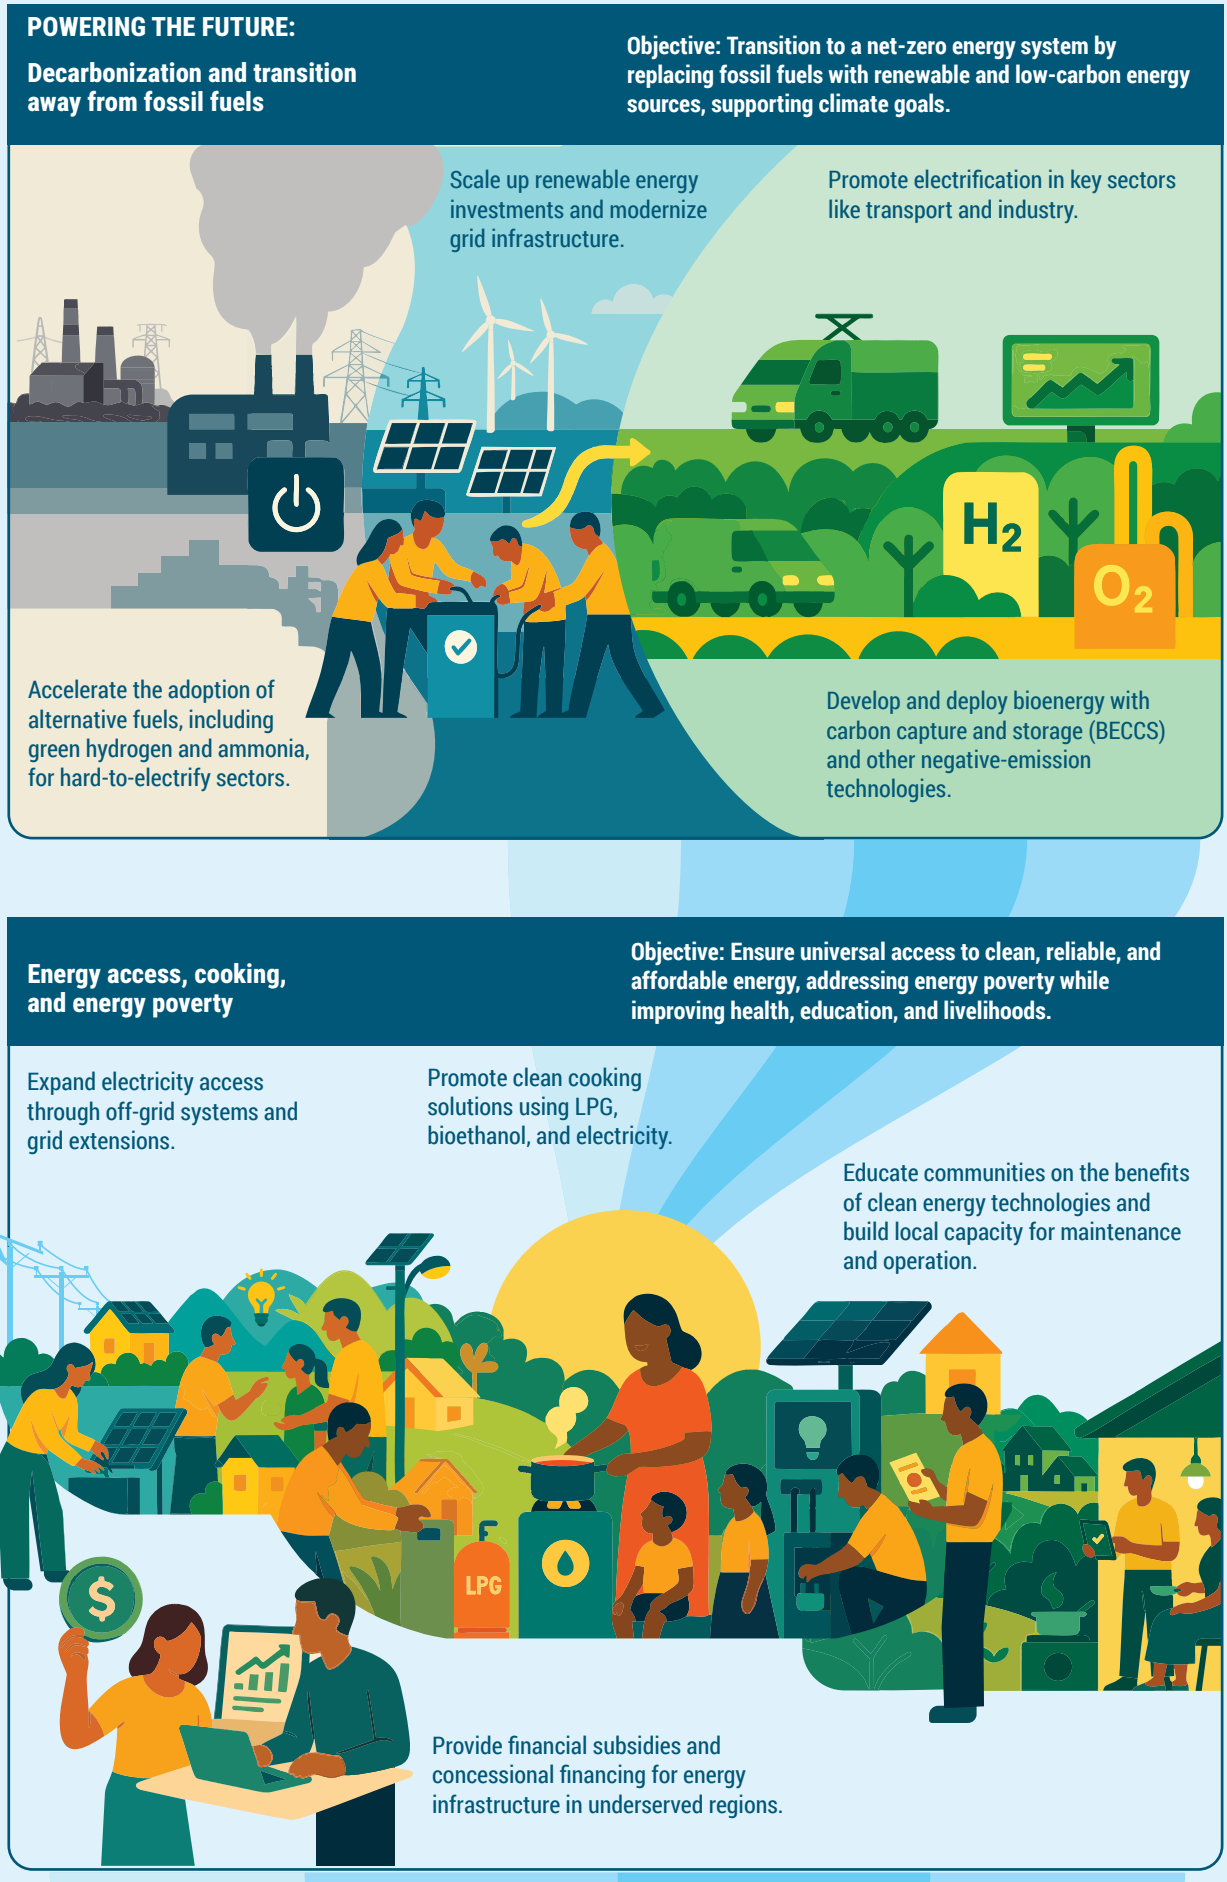
For clean cooking, diversifying fuel sources is essential. While eliminating the use of fuelwood is not yet viable for many rural families, options such as using efficient stoves as a transitional step towards switching to modern fuels or electrification, where feasible, are available.

Achieving universal access to electricity and clean cooking fuels by 2030 is estimated to cost US$45 billion annually. This amount represents less than 2 per cent of total projected spending on clean energy (United Nations 2023). Technically feasible pathways exist, although prioritizing community participation, acceptance, and adoption is essential, alongside significant needs for institutional strength and diverse financial mechanisms.

Figure 16.1: Representative Goals-Solutions-Levers (GSL) Diagram of the Solution Pathways for transformation of Energy Systems

Note: the Feed-in-tariff is not addressed.

Figure 16.2: **Solution Pathways for Energy Transformation**



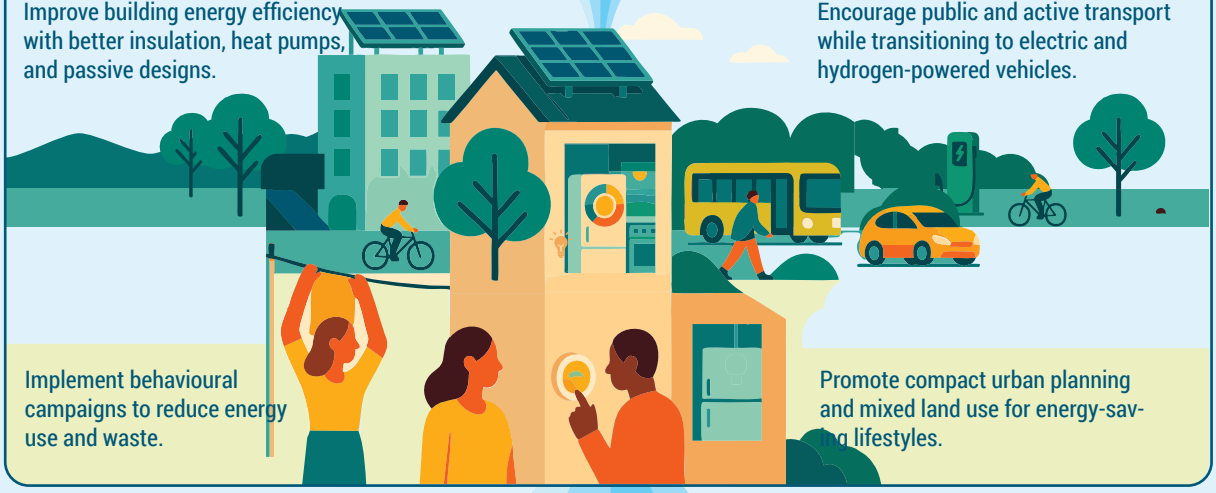


Figure 16.2: **Solution Pathways for Energy Transformation (cont.)**

Energy demand management

Objective: Reduce energy demand through efficiency, behavioural change, and land-use planning, lowering emissions and increasing resource efficiency.

Improve building energy efficiency with better insulation, heat pumps, and passive designs.

Encourage public and active transport while transitioning to electric and hydrogen-powered vehicles.

Implement behavioural campaigns to reduce energy use and waste.

Promote compact urban planning and mixed land use for energy-saving lifestyles.

Sustainable critical energy transition minerals value chains

Objective: Ensure responsible sourcing, production, and use of critical energy transition minerals to support the energy transformation while minimizing environmental and social harm.

Engage local communities and uphold Indigenous rights in mineral development.

Adopt sustainability standards for mining and processing CETMs.

Promote circular economy practices to reduce primary mineral demand.

Foster international cooperation for ethical and sustainable supply chains.

Achieving transformation through synergy

The four pathways must be pursued together to create an equitable, sustainable energy system. Combining these pathways enables co-benefits, reduces trade-offs, and accelerates the energy transition. By addressing systemic challenges and prioritizing inclusivity, these solutions contribute to meeting climate goals, advancing sustainable development, and enhancing global resilience.

Cultural and social factors, including different values and worldviews, as well as consultations and engagement in decision-making, are also crucial for the success of these efforts, especially concerning Indigenous Peoples and women. For example, practitioners are integrating the Mayan Cosmovision, their worldview, into the development of stand-alone solar photovoltaic systems in Indigenous communities in Guatemala. Another example is the need to provide targeted solutions that respond to the context of rural communities in Africa, Latin America and Asia to increase use of different types of efficient cookstoves while highlighting the dangers of relying on fuelwood for cooking (Bharadwaj et al. 2021; Tornel-Vázquez, Iglesias and Loureir 2024).

16.2.1.1 Current landscape

Universal energy access and elimination of energy poverty are critically needed for the growing global population. Efforts focus on expanding energy access through solar home systems, grid expansion, and providing clean cooking solutions. About 13 per cent of the world's population (roughly 940 million people) lacks access to electricity, while 40 per cent of the global population (around 3 billion people) does not have access to clean cooking fuels. (Ritchie et al. 2022). According to the World Energy Outlook 2023, the number of people without access to clean cooking is expected to decline by just over 15 per cent by 2030 (IEA 2023a). However, progress remains slow. Sub-Saharan Africa has seen only 5 per cent growth in access rates, while Latin America, including Mexico and Central and South American countries, has experienced around 4 per cent growth. Accelerated and sustained efforts are essential to meet the SDGs.

In 2019 the global electricity access rate was 90 per cent (Sustainable Energy for All [SEforALL] 2020). However, in the 95 countries with limited access, primarily concentrated in sub-Saharan Africa, only 82 per cent of people have access to electricity (United Nations 2020). Access rates are even lower in specific groups: 53 per cent in the least developed countries, 58 per cent in landlocked developing countries, 83 per cent in small island developing states (United Nations Office of the High Representative for the Least Developed Countries, Landlocked Developing Countries and Small Island Developing States 2021), and less than 10 per cent among displaced populations (NORCAP 2020). About 85 per cent of those without electricity live in rural communities.

Although the world is more than halfway towards achieving universal access to clean cooking worldwide by 2030, the number of people without access to environmentally sustainable, affordable, safe cooking energy is still increasing, especially in developing regions where population growth exceeds progress (IEA 2023a). Lack of access leads to millions of premature deaths each year, with women and children disproportionately affected due to their traditional roles in cooking and gathering fuelwood. Strategies to address this include targeted interventions for women, such as training programmes on the use of clean cooking technologies and financial support for women-led households to adopt these technologies (IEA 2023a). Additionally, women and children often face harassment and injuries when collecting fuelwood, especially during extreme weather events.

16.2.1.2 Solutions for clean electricity for all

Addressing this gap requires understanding the difference between electricity access and coverage, as well as the principles of energy poverty. For example, having access to the grid does not necessarily mean that a family or community can afford the connection or that the quality of service is adequate. Closing both the access and coverage gap can be facilitated through on- and off-grid solutions, although effective social, cultural, institutional, financing, and policy mechanisms still pose significant barriers. Key elements for improving electrification can be summarized as follows (Echevarría et al. 2017; Elabbas, Vries and Correljé 2023; Olówósejéjé et al. 2020; Puig et al. 2021, UNEP 2024a):

- Scaling up off-grid and mini-grid solutions: Depending on the specific context and population density, stand-alone systems may be necessary in areas. However, the greatest potential lies in expanding of mini-grids and distributed generation systems, either through single or hybrid technologies. Mini-grids might also be interconnected, supported by clear regulations and tariff structures, although this may not always benefit end users. Performance-based subsidies can motivate private sector investment.

- Expanding regional power pools: Harmonizing regulations and pricing structures, including bilateral agreements between countries, can

encourage trading, improve investments and build capacity. Expanding renewables-driven transmission infrastructure can support a clean, lower-cost, and more reliable grid. Examples include Electricity Integration of Central America, linking six countries, from Guatemala to Panama with additional bilateral connections between Mexico and Guatemala and Panama and Colombia, and the Southern African Power Pool, spanning 12 countries. These pools provide additional capacity, support integration of intermittent renewable energy generation and improve grid stability.

- Strengthening international funding structures and oversight: Building international partnerships that facilitate compliance and provide checks and balances for financing bodies, while enabling more coordinated and capital-intensive investments. This includes mobilizing concessional finance from

- Establishing supply-side and demand-side standards and incentives to support markets and address the affordability gap: Blended finance, which leverages public or concessional finance to attract private buy-ins, can strengthen the business case for energy projects, especially when supported by risk guarantees to reduce premiums. Demand-side subsidies, targeted for low-income groups and carefully tailored to local conditions, can support both affordability and market development.

- Local capacity is critical for effective policies, projects, workforce and compliance: For example, stable and predictable electricity policies and regulatory environments can improve compliance and development. Aligning local requirements with domestic capabilities supports project outcomes and just transitions. Development and adherence to quality and safety codes, along with certification and training, can prevent failures, ensuring reliability, quality and affordability, while building a skilled workforce.

- Investing in innovative grid technologies and digitalization: Smart grids, smart meters and data systems can improve grid efficiency and stability, enabling lower-cost and more targeted energy delivery. Supporting research and development strategies and startups working with digital innovations and AI can unlock new opportunities for deployment and use.

While grid expansion frequently provides benefits that outweighs the costs, it is not always feasible in rural areas of developing countries. Solar home systems have demonstrated their viability as a reliable source of electricity for households. Since 2015, annual sales of solar home systems with capacities above 11 Watt-peak have increased more than sevenfold in the sub-Saharan region (IEA 2023a). Such systems can supply enough electricity for basic energy needs, including lighting, phone charging, and a radio, although only systems above 50 Watt-peak are regarded as providing essential access (Energy Sector Management Assistance Program (ESMAP), GOGLA, Dalberg 2024.). These systems have also been criticized for not delivering quality electricity to users and for maintaining significant disparities in access and availability in rural areas (Monyei, Adewumi and Jenkins 2018). Enhancing enablers and levers such as donor agendas, training, product guarantees, access to spare parts, and most importantly, the acceptance of end users—who are often not consulted—can improve these outcomes. The installation and expansion of micro and mini-grids are also viable solutions that can give end users greater capacity to operate more appliances. Similar to stand-alone systems, distributed generation can also help create markets and opportunities. When implementing mini-grids as a solution, the challenge of policy restrictions on the sale of excess electricity generated by households should be addressed through inclusive stakeholder engagement.

Community energy access can speed up the shift away from energy poverty. Shared resources, which is a common approach in the health-care sector, can be extended to other community priorities (United Nations 2020). Community systems, regardless of the energy source, can make energy more affordable, especially for solar power (United States of America, Department of Energy 2023). For example, micro, mini, and small-scale hydroelectric systems can enable multiple productive uses and community benefits and can be combined with irrigation schemes to provide additional advantages to the watershed. In the case of communal solar energy, it also enables energy users to subscribe to a shared solar panel system, often

situated within their community, and enjoy the benefits of solar power (United States of America, Department of Energy 2023). There is also the potential to install a community biogas digester, especially in rural areas. However, proper characterization, planning, and definition are necessary to effectively process locally available feedstock. This will ensure the digester's proper performance. Household wastes are common feedstock for biodigesters (16.4) (Nwaigwe, Agarwal and Anyanwu 2018).

16.2.1.3 Solutions for clean cooking for all

A household is considered to have "clean cooking access" when it reliably uses as their primary cooking means, fuels and equipment that significantly limit or avoid the release of pollutants harmful to human health (IEA 2023b). Therefore, a household is considered to have access to clean cooking when it consistently uses one or more clean cooking technologies as its primary cooking mode for most meals, such as stoves using natural gas, liquefied petroleum gas (LPG), bioethanol, biogas, or electricity, (IEA 2023b). A shift towards clean energy sources for cooking entails a significant reduction in particulate matter (PM2.5) and carbon monoxide (CO) levels indoors, thereby reducing health risks (Rosenthal et al. 2018; Shupler et al. 2020). Globally, 2.8 billion people lack access to clean cooking fuels and technologies, which means will continue to face harmful household air pollution (United Nations 2020).

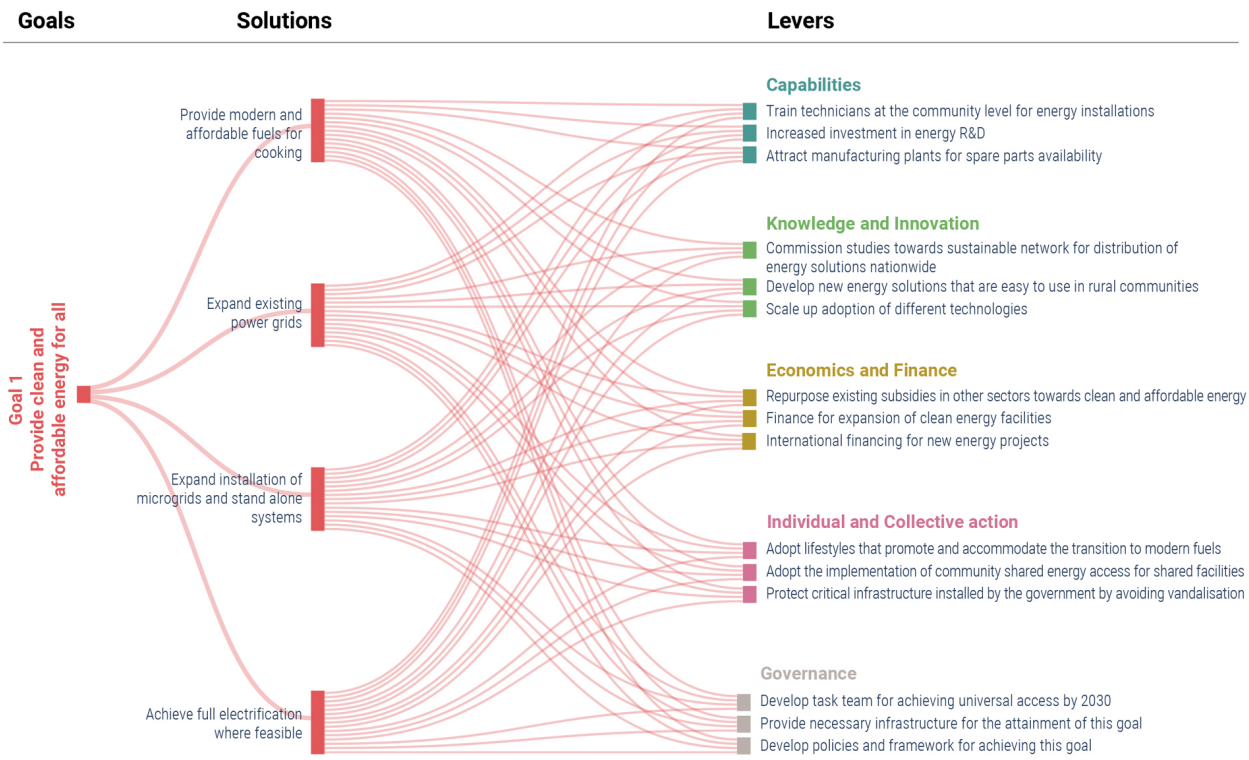
Reaching universal access to clean cooking fuels requires providing over 400 million people with access each year through the rest of the decade, with approximately half of them residing in sub-Saharan Africa. Today, fewer than 20 per cent of clean cooking plans are supported by clear financing schemes (IEA 2023b). The total investment in clean cooking access is significantly lower than what is needed to meet broader climate, health, and energy objectives. Currently, clean cooking investments are around US$2.5 billion annually and need to increase to US$8 billion annually from now until 2030, involving a cumulative investment of about US$60 billion (Coldrey, Lant and Ashworth 2023). Despite having the largest shortfall in clean cooking funding, only 7 per cent of the total investments made in clean cooking in the last five years have gone to Africa (Ritchie et al. 2021).

The expansion of existing power grids can also support clean cooking goals. However, as electrification is still under way, access to clean cooking also needs to be facilitated through modern fuels, specifically LPG for household cooking, and mainly through efficient cookstoves that still use fuelwood. It is crucial to consider the importance of cultural and social understanding and acceptance, which are not always guaranteed in rural communities. Therefore, all available options require proper introduction and acceptance before they can be adopted and used.

To achieve this solution, the following set of actions has proven successful in various contexts and is recommended to improve access to clean cooking (Gould et al. 2024; Kalli et al. 2022; Jeuland et al. 2023; Rochman, Kasim and Atmoko2023; Stritzke et al. 2021):

- Review subsidies: Governments should conduct a study to understand past challenges in cooking fuel subsidies, including implementation challenges that may hinder the provision of modern fuels to households.

- Track subsidized fuel purchases: Develop a database to monitor subsidized fuel purchases, limiting the quantity per person. Eligibility
should be income-based, initially targeting the formal sector.



- Include informal communities: Local authorities should develop approaches for the distribution of cooking fuel via informal communities, considering living spaces and employment.

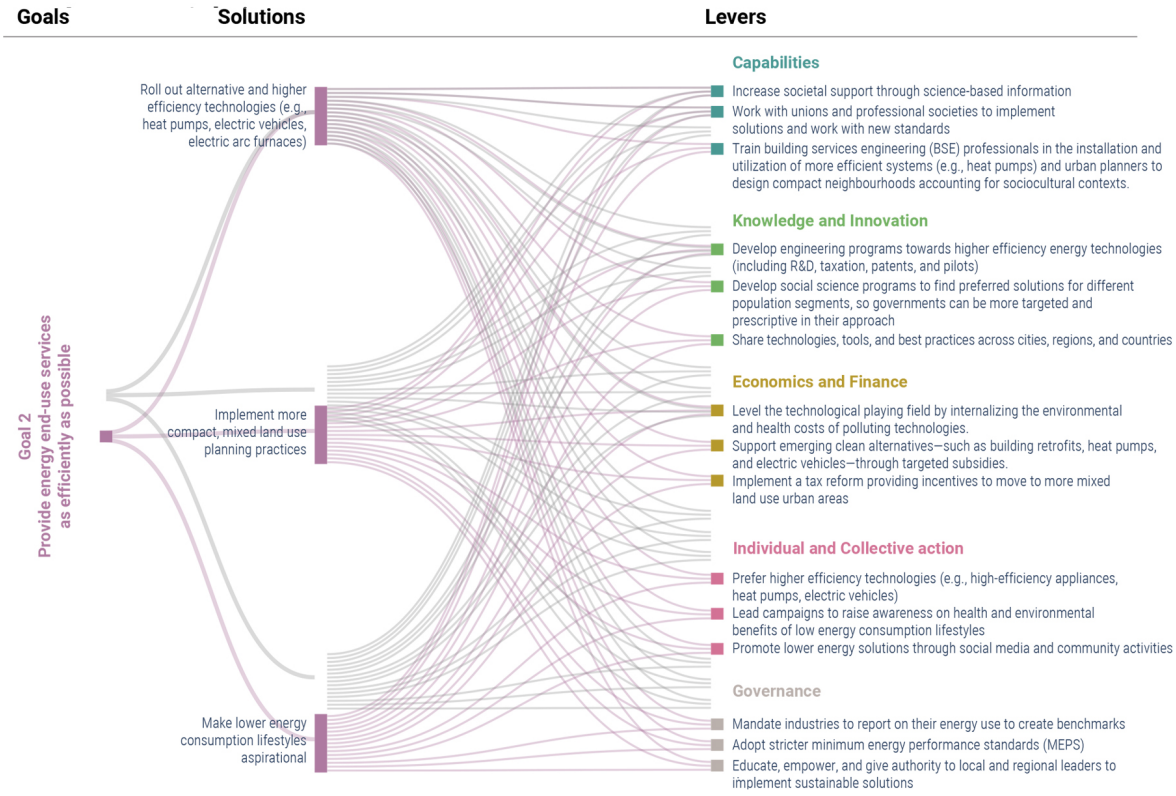
- Subsidize LPG: Governments should establish appropriately scaled financial subsidy for LPG.

- Support stove access with loans:Governments should consider providing financial subsidies and no-interest loans to low-income citizens for the purchase of safe, mechanically actuated LPG gas stove systems. The loan terms need to minimize financial burden for citizens, with disbursement facilitated through existing networks of commercial banks in coordination with governmental initiatives.

- Ensure safe infrastructure: Authorities need to mandate standards for safe LPG gas

Figure 16.3: Illustrative Goals-Solutions- Levers (GSL) diagram to show combination of solutions and levers to achieve goal 1

piping and regulators to connect the 12 kg size tanks to stoves.



- Build community-level distribution networks: Establish local depots for subsidized LPG distribution to prevent monopolization. Tribal leaders should be involved in the distribution.
- Develop transport infrastructure: Create transport networks to supply remote and underserved communities.
- Certify and regulate: Implement state certification processes to ensure integrity of markets, components, products, installers, etc.
- Support adoption through capacity development: conduct education and training campaigns to introduce modern cooking technologies and address cultural barriers. Provide training on safe and effective use.
- Facilitate uptake through community demonstration initiatives: Launch demonstration initiatives at community-shared facilities to overcome the fear of new technologies.

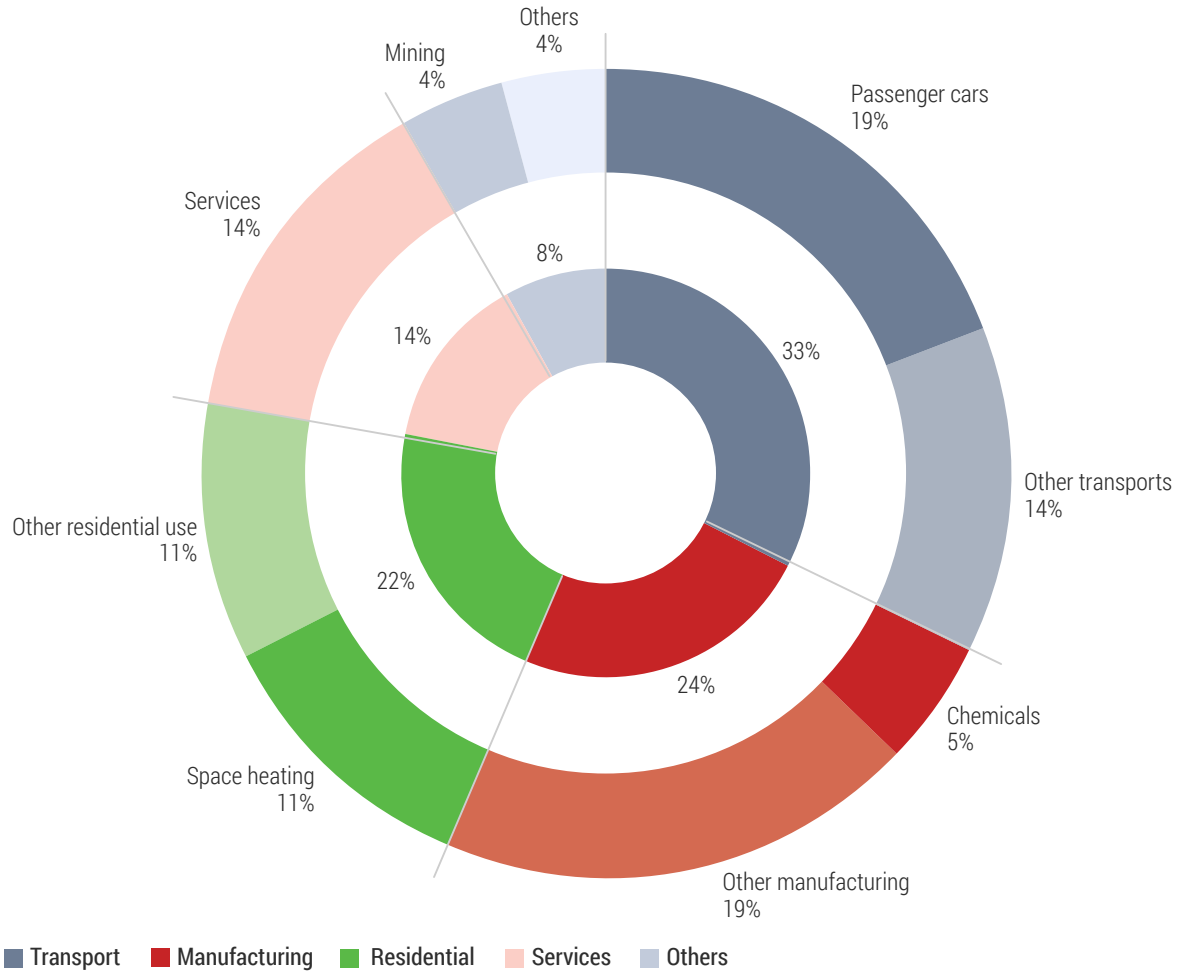
There are social and behavioural consequences stemming from a lack of access to energy, and Indigenous Peoples are especially vulnerable. Each year, millions of premature deaths occur, with women and children being disproportionately affected, as one in three people in the poorest regions still cook over traditional open fire stoves, inhaling dangerous smoke daily (Malakar and Day 2020; IEA 2023b). In many rural communities, there is a cultural attachment to traditional cooking methods. Relevant government agencies must collaborate with local communities to transition to culturally appropriate, yet safe and efficient, cooking techniques.

Considering the negative effects of lack of energy access and energy poverty on large populations in developing countries, there is an urgent need to accelerate this transformation (Bonan, Pareglio and Tavoni 2017). To achieve the target set in SDG 7.1, it is recommended that the governments of developing countries establish and empower national task forces to ensure universal energy access by 2030 (United Nations 2020).

To achieve the necessary goal of providing clean and affordable energy for all, a summary of key solutions and actions is presented in **Figure 16.2**.

Figure 16.4: Illustrative GSL diagram to describe which combination of solutions and levers will achieve goal 2

16.2.2 Solution pathway 2: Improve energy management



From buildings and transportation to electricity and stormwater, all infrastructure sectors require energy. Demand can be reduced through energy efficiency, land-use planning, and behavioural change. Energy efficiency solutions use better designs and technologies to replace or improve existing energy end-uses with a lower energy footprint, such as heat pumps instead of conventional furnaces. Land-use planning strategies promote practices that support lower energy consumption lifestyles and enhance human well-being – accessible jobs and grocery stores within a short distance of home – while safeguarding natural habitats. Behavioural change initiatives encourage people to reduce and conserve their energy use by adjusting their behaviour towards turning off equipment when not in use, switching travel modes, and recycling, for example.

Raising awareness and establishing the right regulatory and financial environments to encourage energy-demand reduction is crucial for gaining public acceptance and minimizing obstacles to implementation (Susskind et al. 2022; Ibrahim 2023; Carlander and Thollander 2023). Economic incentives such as subsidies for heat pumps and charging stations for electric vehicles, congestion pricing, or asymmetric property taxation could be introduced. Research and development programmes can be created to devise better energy-efficient technologies, to promote urban designs that are more sustainable, resilient and equitable, and to support more focused education campaigns that address the needs and concerns of various population segments.

16.2.2.1 Current landscape

The three largest energy end-uses are manufacturing, space heating, and passenger cars (**Figure 16.5**). The building sector accounts for 30 per cent of global energy consumption and 26 per cent of global energy-related emissions (IEA 2023c). Within buildings, space and water heating and cooling account for approximately 50 per cent of energy use (IEA 2023c), rising closer to 70 per cent in some regions (Derrible et al. 2021). The Buildings chapter of the IPCC's Sixth Assessment Report outlines many strategies to curb building energy demand (IPCC 2022b). Western cities generally expand with suburban areas that are less dense compared to their city centres. In contrast, residents of dense urban areas tend to consume less energy, have shorter or walkable commutes,

Figure 16.5: Energy use by sector in IEA countries in 2021

Source: IEA (2025)

and take public transport (Wiedenhofer, Lenzen and Steinberger 2013; Facchini et al. 2017).

16.2.2.2 Solutions for land-use planning

Energy consumption tends to be lower in mixed-use and more compact cities. Mixed land use as a combination of residential and commercial buildings leads to shorter distances to reach a destination. Denser street networks encourage walking and cycling. Smaller dwellings often require less energy (Estiri 2015; Bowley and Evins 2020).

In Europe, many cities densified in the 2010s, in part by leveraging real estate market mechanisms (Semprini et al. 2017; Cortinovis, Geneletti and Haase 2022). The fifteen-minute city concept can promote this densification by establishing most work, school, recreational and shopping amenities within a fifteen-minute walk, bike ride, or transit ride. This concept has been adopted and implemented in cities of all sizes and land-use patterns, from large, dense cities like Paris (World Resources Institute [WRI] 2023) to small, suburban communities like O'Fallon, Illinois, in the United States (O'Fallon Illinois 2022). When appropriately implemented with smooth sidewalks and no steps, the concept also has the potential to meet the needs of people with physical disabilities (Zivarts 2021; Buliung 2024). The C40 knowledge hub offers resources to implement this concept and showcases several case studies (C40 Cities Climate Leadership Group 2022).

Infrastructure, design, and maintenance practices need to be developed for both growing and shrinking cities (Zhai et al. 2022). In the United States, about half of the existing 30,000 towns are expected to lose population before 2100 (Sutradhar et al. 2024). Sethi et al. (2020) find that retrofitting existing urban areas and planning new compact urban areas can reduce GHG emissions by 50 and 23 per cent, respectively.

Land-use solutions are typically decided locally and encounter challenges such as high upfront costs and confusing, uncertain, or conflicting funding mechanisms (Khosla and Bhardwaj 2018). Local actions also require buy-in from both communities and land developers. Public campaigns, training sessions, and workshops help educate the public and local and regional actors, along with programmes that promote desirable and culturally sensitive land-use practices.

16.2.2.3 Solutions for more efficient technologies

New and more efficient technologies hold significant potential for reducing energy use. Even a non-exhaustive list of solutions by sector and their potential for energy reduction offers a wide selection of options (**Figure 16.6**). The effectiveness of these solutions is well established. The potential for reducing energy demand is provided as a general guideline, but it varies depending on the context. In particular, to adapt to climate change, further research is needed to better understand and manage the interdependencies and interrelationships between infrastructure systems (Movahedi and Derrible 2021; Movahedi et al. 2023).

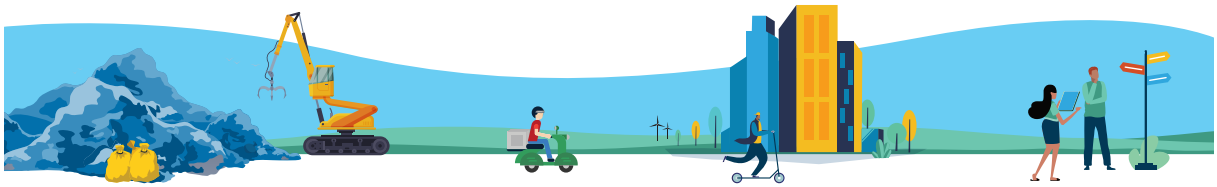
16.2.2.3.1 Actions for buildings

Nearly net-zero energy, or low-energy, buildings are possible in most climate zones (IPCC 2022b; Reinhart 2025). Depending on local conditions including climate and technology availability, building retrofit efforts can reduce energy use by 13 to 36 per cent with shallow measures such as efficient lighting and appliances and 34 to 84 per cent with deep measures that involve better insulation and heat pumps, for instance (Ang et al. 2023).

Implementing heat pumps globally would reduce building energy demand. Heat pumps are three to five times more efficient than traditional technologies (IEA 2022a) and can be used for space heating, cooling, and water heating. As electrical devices, heat pumps increase electricity use, particularly during cold days in colder regions. Therefore, it is crucial to promote weatherization programmes, such as retrofitting buildings to suit the local climate, while also decarbonizing the electricity grid.

Heat pumps can also be strategically positioned. The Stockholm district heating network uses heat extracted from energy-intensive data centres to warm buildings. This could additionally support the information and communications technology sector, which consumes significant energy for cooling. (UNFCCC 2023a).

Passive designs that leverage natural shading and ventilation can reduce the energy needs for space heating, cooling, and lighting (Zhang et al. 2021; UNEP 2023). Positive-energy buildings can even produce more energy than they consume (Belleri et al. 2023).



Green and energy-efficient buildings rely on the development of innovative, green-based, locally sourced materials to reduce heating loads in winter and cooling loads in summer. New materials, such as low-carbon alternatives to bricks and concrete blockwork, have been developed using natural fibres from agricultural waste and other low-cost materials (Goodhew et al. 2021, Touati et al. 2023). Green materials are also easier to dispose of. Solar-powered technologies such as solar water heaters can meet water heating needs.

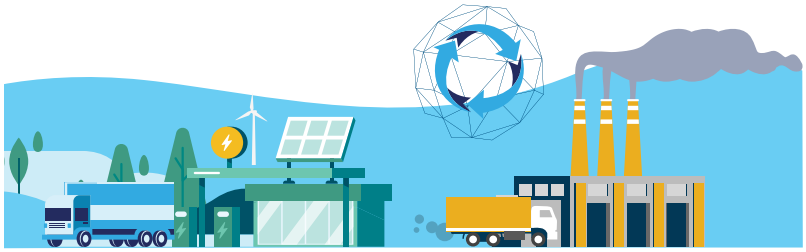
Nature-based solutions such as green and blue infrastructure also offer many ecosystem services that can help reduce energy demand (Seidu et al. 2025). Rain gardens, bioswales, and sponge cities capture stormwater and prevent floods, reducing the need for pumping while also replenishing groundwater (McFarland et al. 2019). They can be implemented at various scales, from private homeowners to large building complexes and entire neighbourhoods, often supported through government programmes that educate the public about the practical and financial benefits of nature-based solutions (Dhakal and Chevalier 2017).

Energy-efficient equipment, such as smart thermostats, water heaters, and motion detectors for lighting can reduce energy waste. Smart meters allow real-time monitoring of energy use. Demand response strategies that encourage people to lower their consumption during peak periods can reduce the need for peaking power plants, which are often old and inefficiently powered by fossil fuels (Greening 2010; IEA 2024).

Stricter minimum energy performance standards can also encourage the adoption of new technologies, such as replacing conventional gas furnaces and boilers with heat pumps or enhancing building insulation. This can be further supported by international building labels and

Figure 16.6: Solutions by sector and their energy demand reduction potential

Solid waste



- Design products with recycling / elimination of waste in mind
- Organize recycling campaigns and programs
- Establish networks of industries for the recycling, repurpose, and remanufacturing of recyclable waste
- Reduce waste disposal
- Reuse products
- Recycle all waste that can be recycled
- Promote long-lasting product design
- Develop technologies to make more waste recyclable

Land use

- Medium to high densities of housing, jobs, and businesses
- Mixed land-use planning
- Denser street network/smaller blocks
- Transit-oriented development (TOD)
- Green and blue infrastructure

Buildings

- Air-source or ground-source heat pumps for space heating and cooling
- Right sizing (not too big)
- Compact buildings (minimize surface area exposed to outdoors
- Passive designs (natural shading and ventilation)
- Building insulation
- White-blue-green roofs
- Solar thermal systems (water heating)
- High efficiency air conditioners
- Adopt stricter minimum energy performance standards (MEPS)
- Building orientation
- Sealing leaks
- High efficiency windows (double or triple pane with low emissivity glass)
- Reflective (low-emission) materials for walls and roofs
- Smart buildings (Buildings Management Systems (BMS)
- Smart thermostat
- High efficiency appliances
- Dynamic demand (appliances partly controlled by utility provider such as refrigerators and EV charging)
- District heating and cooling networks for dense areas
- Solar panels (prosumerism)
- Phase out incandescent light bulbs universally
- Universal adoption of smart meters
- Regulate thermostat settings, especially in commercial buildings
- Turn equipment off or down when not needed
- Adjust water heater setting
- Adjust thermostat

Transport

- Shift fossil fuel-powered vehicles to electric and hydrogen
- Dense street network conducive to active and public transport use
- Adopt energy-efficient technologies for aviation and shipping
- Promote active and public transport use
- Reduce long-haul flights
- Ban short-haul flights and shift to train when possible
- Encourage people to walk and bike, and ride public transport
- Advance vehicle light-weighting
- Promote telework, telemedicine, distance learning
- Carpooling

Industries

- Electrify low-temperature heat applications
- Promote best available technologies (BAT) across the iron and steel sector, including scrap-based electric arc furnaces
- Replace old, inefficient equipment
- Use high efficiency electric motors
- Reuse and recycle construction and demolition waste from industries
- Promote and facilitate industrial symbiosis
- Promote and facilitate circular economy
- More efficient process designs

*The list is not exhaustive. Energy demand potential reduction offers a general indication and is context-dependent

Low-medium-high energy demand reduction potential

Solution type: Design; Technology; Institutional; Behaviour

certifications like Energy Performance Certificates in Europe and Leadership in Energy and Environmental Design and WELL Building Standard in the United States. Building energy labels have effectively stimulated private interest and investment in improving building energy efficiency (Gerassimenko, Defau and De Moor 2024; Khazal and Sønstebø 2023). These certificates provide a thorough energy assessment of a building, informing owners about possible efficiency upgrades and acting as an estimate for energy costs for prospective tenants or owners.

16.2.2.3.2 Actions for transport

Electricity- and green hydrogen-powered vehicles can help decarbonize the transport sector. Electricity is preferable for vehicles, hydrogen for aircraft, and hydrogen-based fuels for vessels (16.2.3.2). In some contexts, compressed biogas from the anaerobic digestion of organic waste such as post-harvest residue and manure offers potential as a short-term transport fuel (Xia, Cheng, and Murphy 2016; Nouni et al. 2021).

Various policies, programmes, and incentives exist, ranging from subsidizing the retrofit of existing vehicles to encouraging the purchase of new vehicles and building charging stations. Replacing one vehicle with another is not sustainable in areas that experience chronic traffic congestion. Traffic congestion affects energy consumption, economic growth, and human well-being. Travel demand management strategies can be implemented to reduce traffic congestion. These include promoting active and public transportation, incentivizing carpools through high-occupancy vehicle lanes and other tools, and encouraging remote work arrangements (Victoria Transport Policy Institute [VTPI] n.d.; IPCC 2022b).

Active and public travel modes are preferred. Insufficient investment in and promotion of public transport increases congestion and hampers economic development (Organisation for Economic Co-operation and Development [OECD] 2020). Active transport, such as walking and cycling, also offers health benefits (Mizdrak et al. 2023) and improves satisfaction (Schwanen 2021). To make active and public transport appealing, infrastructure must be in place, including sidewalks, bicycle routes, bicycle parking, transit-oriented development, integrated public transport routes, and denser street networks. (National Association of City Transportation Officials [NACTO] n.d.; Institute for Transportation & Development Policy [ITDP] n.d.; WRI 2021; Derrible 2025).

With air transport, short-haul flights have a higher emission factor per kilometre than medium and long-haul flights. Many regions offer lower-energy trains and buses to short-haul destinations. France has banned short-haul flights when a train alternative is available with a travel time of 2.5 hours or less. Many meetings can also be held online; a 50 per cent switch to online meetings with a careful selection of transport hubs to hold meetings is estimated to reduce carbon emissions by 60-70 per cent (Tao et al. 2021).

16.2.2.3.3 Actions for industry

Governments can require industries to report their energy consumption for benchmarking and use this data to analyse energy use patterns, which can lead to reduced energy demand. Maintaining and promptly replacing old equipment provides key opportunities to cut energy demand (IEA 2021a). When replacing equipment, industry can adopt best available techniques, such as using electric arc furnace technologies or hydrogen-based direct reduction processes (Kim et al. 2022). Bifacial and translucent solar technology that lets light in and generates electricity can be installed on roofs or covers of industrial warehouses, as well as agricultural and commercial roofs (Gupta, Kumar and Singh 2024). Many industries employ dedicated managers or work with energy consultants to monitor their energy consumption. Collaborating with these specialists offers opportunities to identify effective energy reduction strategies that consider local conditions. (Zierler, Wehrmeyer and Murphy 2017; Oksman et al. 2021; Succar et al. 2023).

The concept of industrial symbiosis also offers opportunities to create networks of industries located near one another that share or exchange goods (15.3). For example, several industries can collaborate on a district heating or cooling system. Kalundborg in Denmark provides a good example, involving 16 public and private companies (Chance et al. 2017). Creating networks for recycling, repurposing, remanufacturing, and reusing materials – especially metals, plastics, and glass – as well as reusing waste heat, presents important and often untapped opportunities to cut energy use. These solutions are usually carried out by networks of co-located industries, but they can also be encouraged or catalysed by governments.

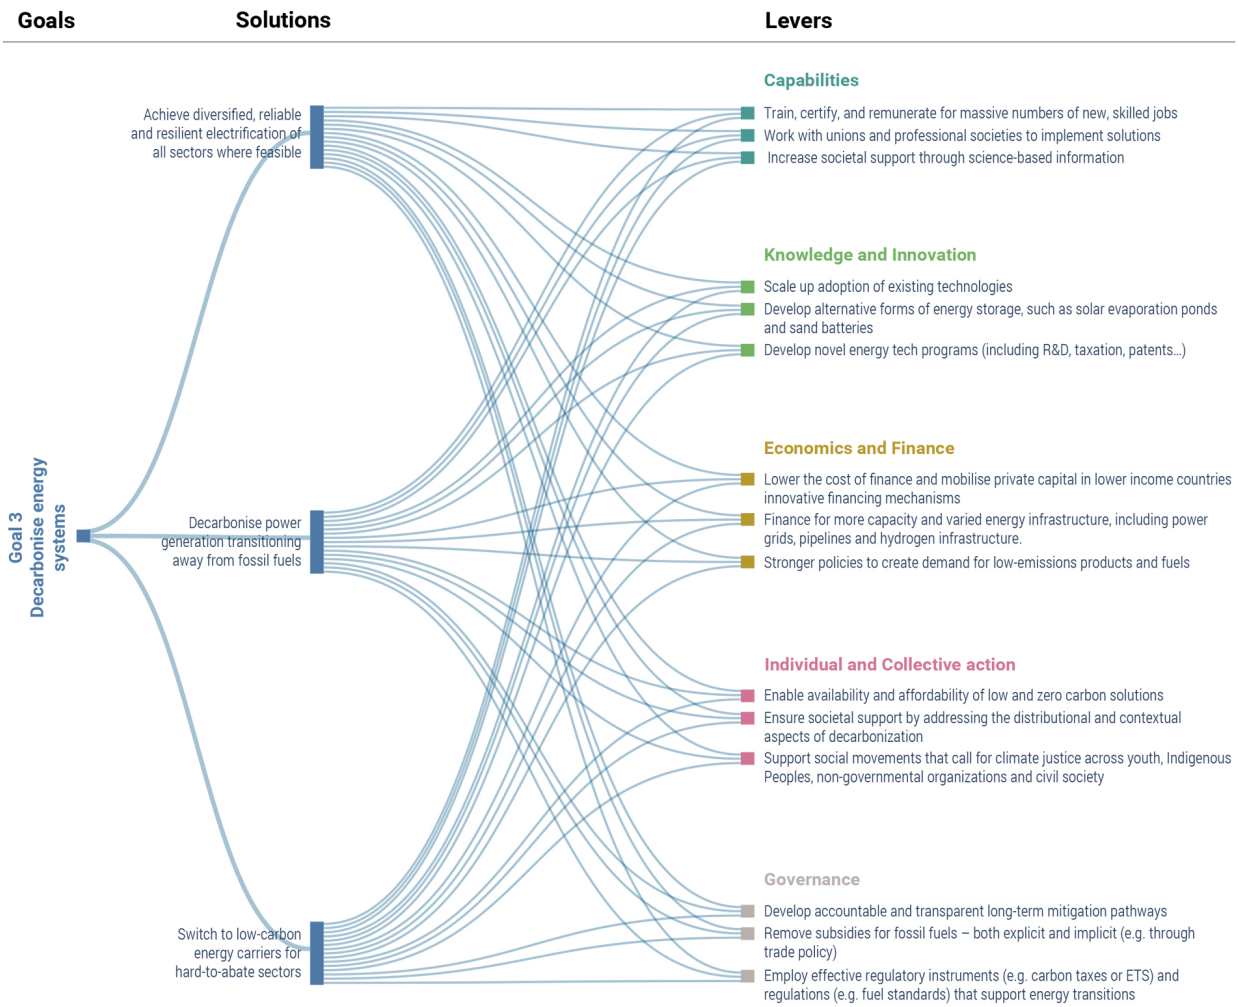
16.2.2.3.4 Actions for solid waste

Figure 16.6 shows conventional solutions to reduce energy demand and emissions from the solid waste sector. According to the IPCC's Sixth Assessment Report, end-use strategies, including increasing the reusability, recyclability of products and materials, and adopting materials-efficient services, can reduce emissions in the industry sector by 29 per cent, 4.4 $GtCO_2$, by 2050 (IPCC 2022b). Further, applying circular economy strategies in the five key sectors of cement, aluminium, steel, plastics, and food can reduce 9.3 $GtCO_2$ equivalent in 2050, which is equivalent to all transport emissions (Ellen MacArthur Foundation and Material Economics 2021).

16.2.2.4 Solutions for behavioural interventions

Public support for extensive action to combat climate change is growing (United Nations Development Programme [UNDP] 2021; Dechezleprêtre et al. 2025). This can be leveraged to promote lower-energy lifestyles and compact living arrangements, focusing on benefits to human health and personal finances, not just the environmental impacts. Lower consumption will also require supporting infrastructure, such as adequate public transit systems or bicycle paths.

Programmes that target behaviour change have the potential to curb energy demand while being cost-effective and offering direct and indirect financial benefits (Kastner and Stern 2015). Zhang et. al (2018) estimate that behaviour change can lower energy demand between 10 per cent and 25 per cent for residential buildings and between 5 per cent and 30 per cent for commercial buildings. Many programmes, however, have limited success because they fail to reach their target audience. Research funding can be allocated to identify preferred solutions for different population segments and develop decision-making tools, enabling governments to be more targeted and prescriptive in their approach (Fontecha et al. 2022). In the European Union, programmes like Playing My Part have been successful in raising awareness and involving people more directly (IEA 2022b). A promising but underutilized strategy to align perceptions with objective realities (Bell and York 2010) is to hire social media influencers to convey positive and energy conservation messages to their followers (Bhukya and Paul 2023, Agarwal, Kumar, Gunasekaran 2024). For example, in mid-2024, the concept of "underconsumption core" trended on social media. The concept encouraged people to buy only what they needed (Fares and Lee 2024). The adoption of information-based tools such as energy labels on appliances has also gained popularity. While they may influence people's purchasing behaviour, the relationship is complex and often not sufficient (Zainudin et al. 2014; Beck and Özçaglar Toulouse 2023; Basiru et al. 2024).



16.2.3 Solution pathway 3: Decarbonize and transition away from fossil fuels

While it remains technically feasible to reach the Paris temperature targets, comprehensive regulatory and economic approaches to support these pathways are essential. Affordable and reliable technologies, such as the rapid decrease in prices and effectiveness of solar and wind power, can support electrification. Diversifying energy systems requires regulatory and long-term certainty to drive adoption and develop new markets. Increasing and retraining the workforce can support just transitions, while implementation efforts should recognize that livelihoods are deeply tied to cultural and social ways of life.The experience of the Pavagada solar park in Karnataka, India illustrates this point, where landless agricultural labourers not only lost their primary income sources but also their connections to land-based traditions and community identities, underscoring the importance of more democratic ownership and governance of renewable energy initiatives (Ghosh, Bryant and Pillai 2023).

16.2.3.1 Current landscape

The costs of renewable energy, particularly solar photovoltaics, wind power and batteries, have fallen rapidly. Their cost reductions and faster adoption rates have surpassed those of other technologies such as fossil fuels combined with carbon capture and storage or bioenergy with carbon capture and storage (BECCS). (IPCC 2022b). Solar and wind energy registered record investment levels in 2022, with a growth of 266 gigawatts (GW) in generating capacity (Energy Institute 2023), including in developing countries (Nwaigwe 2022). Renewable energy production increased by 14 per cent in 2022, with notable increases in the Middle East at 19.9 per cent and Asia and the Pacific at 17.6 per cent. However, despite significant growth in renewable energy, around

Figure 16.7: Illustrative GSL diagram to describe which combination of solutions and levers will achieve Goal 3

four times more electricity was generated by coal, oil, and gas with 17,677 TWh than by renewable sources with 4,204 TWh in 2022 (Energy Institute 2023).

Global greenhouse gas emissions reached a record high of 53.0 $GtCO_2$ equivalent in 2023. Most of these emissions came from fossil CO_2, accounting for 73.7 per cent of the total, while methane contributed 18.9 per cent, nitrous oxide 4.7 per cent, and fluorinated gases 2.7 per cent (Crippa et al. 2024). The IEA Net Zero Roadmap can serve as a guide to the emissions from the energy sector (IEA 2023d).

16.2.3.2 Solutions for the electrification of all sectors

Limiting warming to 1.5°C by the end of the century requires a rapid increase in energy produced from low- or zero-carbon sources, reaching 74–82 per cent of primary energy in 2050, up from below 20 per cent in 2019 (IPCC 2022b). This transition needs to be supported by electrification of the most intense energy sectors, such as transportation, heating, and industry, powered by low- and zero-carbon energy.

Developing a diversified, reliable and resilient electrification of all end-uses and sectors, along with decarbonizing electricity generation, is a crucial near-term strategy for limiting warming (Clarke et al.2022). In scenarios that aim to limit warming to 1.5°C (>50 per cent with no or limited overshoot), low- and zero-carbon sources produce 97–99 per cent of global electricity in 2050. Even in scenarios that limit warming to 2°C (>67 per cent), 93–97 per cent of electricity still comes from low- and zero-carbon sources. By 2030, zero-carbon electricity generation should account for 62-92 per cent, alongside the phaseout of unabated

coal generation (Clarke et al.2022). Renewable electricity is growing exponentially rather than linearly, aligning with net-zero pathways by 2050 (WEF 2023a). However, land-use competition for renewable energy, such as solar and wind, and particularly bioenergy cropland in densely populated countries, may limit growth (van de Ven et al. 2021; Braun et al. 2025).

A major obstacle to expanding renewable energy is the existing grid system, which in many cases is outdated and lacks sufficient capacity, especially for the anticipated growth in renewable energy. Investment in grid infrastructure track with net-zero emissions by 2050 (IEA 2022c). Additionally, to balance the intermittent supply from solar and wind and stay on track to reach net zero by 2025. This can be supported by alternative energy storage methods, including hydrogen and other technologies that require further development, such as solar evaporation ponds, sand batteries, flow batteries, and gravity storage. Other barriers include the availability of critical energy minerals and expanding energy access to communities without electricity, as discussed in Sections 16.2.4 and 16.2.1, respectively.

16.2.3.3 Solutions for transitioning away from fossil fuels

The key to progressing on these pathways is transitioning away from fossil fuels. By 2030, demand for oil and gas needs to decline by approximately 20 per cent, which is consistent with the need to stop new conventional development of oil and gas (International Institute for Sustainable Development [IISD] 2022; IEA 2023a). Phasing out fossil fuels is technically feasible and is estimated to be relatively low in cost (IPCC 2022b).

Greater energy system integration across energy sources and regions is essential to enhance energy systems' flexibility and efficiency, optimize costs, and bridge regional energy disparities. System integration can also support aligning different policy objectives beyond energy supply, including sustainable development and carbon dioxide removal (CDR). Major contributions to emissions reductions at costs below US$20 per tCO_2-eq^{-1} come from solar and wind energy, energy efficiency upgrades, and reductions in methane emissions from coal mining, oil and gas, waste and other sources (IPCC 2023a).

Energy crops, biogenic waste and residues feature prominently in mitigation pathways that limit global warming to 1.5°C by the end of the century, either as feedstock for low-carbon bioenergy, or for carbon removal through BECCS or biochar, a carbon-rich, stable substance produced by heating biomass in a low-oxygen setting (IPCC 2018). By 2050, the IPCC's Sixth Assessment Report mitigation pathways with no or limited overshoot project a median annual delivery of 118 exajoules of primary energy via bioenergy and 3.8 gigatons CO_2 removed annually with BECCS deployment (Byers et al. 2022). However, large-scale deployment generates trade-offs related to land, water, and fertilizer demand with implications for food security and biodiversity conservation, which may substantially constrain sustainable expansion of bioenergy cropland with or without carbon capture and storage (IPCC 2023b; Deprez et al. 2024; Braun et al. 2025).

Rapid and deep decarbonization is required to preserve CDR methods for truly critical needs in hard-to-abate sectors (Buck et al. 2023; Shindell and Rogelj 2025). A portfolio approach is required to balance the diverse trade-offs of CDR options in terms of implementation challenges, environmental implications, and impacts on economic prosperity and well-being (Fuss et al. 2020; Prütz et al. 2024). However, CDR is needed in the context of net-zero CO_2 to balance any residual emissions from hard-to-abate sectors (Rogelj et al. 2018a; Luderer et al. 2018; Strefler et al. 2018; IPCC 2022b), such as aviation, shipping, or industry (IPCC 2022b). Beyond net-zero CO_2, CDR is also necessary to achieve net-negative CO_2 emissions, to reverse warming after a temporary temperature overshoot (Rogelj et al. 2018b). As mentioned previously, CDR remains unproven at scale and poses severe trade-offs related to land, water, energy, and fertilizer demand, with implications for biodiversity conservation and food security (Deprez et al. 2024; Prütz et al. 2024; Braun et al. 2025).

16.2.3.4 Solutions to switching to low-carbon energy carriers

Alternative fuels or energy carriers such as advanced biofuels, hydrogen, ammonia, or synthetic methane are needed to support decarbonization in

sectors that are harder to electrify (IPCC 2022b). These sectors include freight, aviation, shipping, and energy-intensive industries. Hydrogen and ammonia can also serve as replacements in fossil-fuel power plants, playing a crucial role in ensuring electricity security during clean energy transitions (IEA 2021b). Additionally, their growing importance as energy storage – converting surplus electricity into hydrogen through electrolysis and reconverting it into power, for example – highlights their significance in the clean energy transition. (Aneke and Wang 2016).

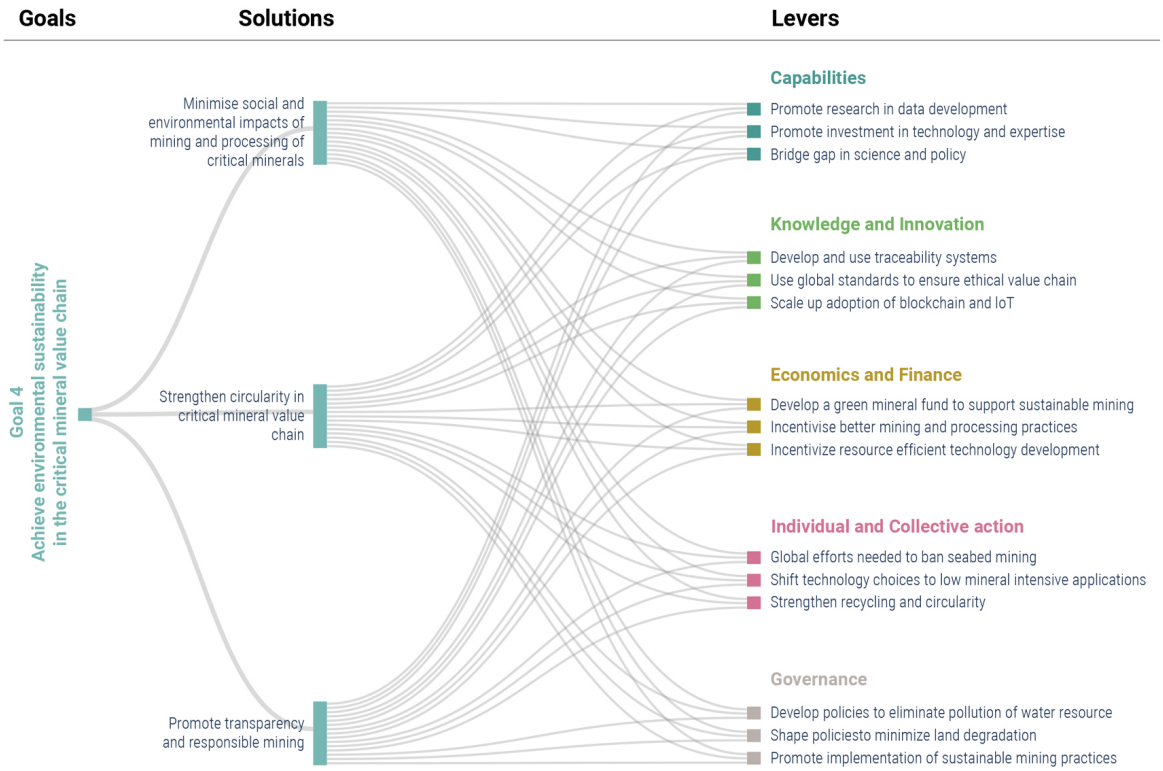
Green hydrogen is expected to contribute to 14 per cent of the final energy demand by 2050, helping meet the 1.5℃ by the end of the century (International Renewable Energy Agency [IRENA] 2023). This entails an expected installed capacity of 5,700 GW by 2050, a fivefold increase from 2020 (World Trade Organization [WTO] and IRENA 2023). Shifting from hydrogen, currently a net emitter, to green hydrogen requires producing it from zero-carbon or extremely low-carbon energy sources. The cost-effectiveness of green hydrogen is supported by increasing renewable capacity and decreasing the costs of electrolysers. The development of green hydrogen supply has been hindered by the current lack of demand. However, credible decarbonization policies and transitions for fossil fuels should boost demand.

Green hydrogen is considered one of the leading decarbonization pathways for the steel and chemical sectors. It can be used in a variety of industrial processes, such as replacing coal as a reducing agent in the steel production, substituting oil as raw material in the chemical industry, and for heating in industrial furnaces for the glass, cement and steel industries (United Nations Industrial Development Organization [UNIDO] 2022). If green hydrogen can be used at scale to process iron ore, steel production can be carbon-neutral (IPCC 2022b). As for the chemical sector, about 28 per cent of emissions reduction from the sector can be achieved using electrolytic hydrogen by 2050 (IEA 2023d).

With electric aviation still in its early stages and limited to smaller electric aircraft (Schwab et al. 2021), alternative fuels are a key to decarbonizing aviation. Renewable jet fuel only accounts for less than 0.1 per cent of the current global jet fuel demand. Eventually, hydrogen-fuelled aviation could be cheaper than using kerosene, although it would require approximately four times more fuel by volume (Yusaf et al. 2024).

16.2.4 Solution pathway 4: Shift to a responsible and sustainable Critical Energy Transition Mineral Value Chain

The shift to clean energy is mineral intensive. Approximately 30 to 50 minerals, including rare earth elements, remain critical for energy system transformation. The list of these critical energy transition minerals (CETM) varies across different countries, depending on their availability and accessibility (e.g., Government of Canada 2022).



The three main strategies for the CETM value chain are to reduce social and environmental impacts, enhance circularity and resource efficiency, and establish a just and responsible value chain with benefit-sharing mechanisms. Eliminating water pollution is essential for all stakeholders, which requires strict regulations on the contamination of surface and groundwater sources. Similarly, attention must be given to reducing land degradation, as it can threaten food systems and biodiversity if neglected. The rights of Indigenous Peoples and CETM value chain workers must also be protected, and any harm to their livelihoods, as well as the livelihoods of surrounding communities, needs to be addressed.

16.2.4.1 Current landscape

The total mining production including that of mineral fuels grew from 11.3 billion metric tons in the 2000 to 17.9 billion metric tons in 2021 (Austria, Federal Ministry of Finance and International Organizing Committee for the World Mining Congress 2023). Demand for CETMs could surge significantly in the coming years (United Nations 2024). Minerals such as graphite, lithium, and cobalt could see a nearly 500 per cent increase by 2050 compared to 2018 (Hund et al. 2020). The COP28 goal to triple the renewable energy capacity worldwide could significantly increase demand for CETM supplies. The CETM production grew by 30 per cent in 2022, compared to the previous year (IEA 2023g). Over the last decade, reserves of lithium and copper grew by 40 per cent and 30 per cent, respectively (IEA 2022d).

Over 23 million people worldwide are estimated to be negatively affected by toxic pollution in land and

Figure 16.8: Illustrative GSL diagram to show combination of solutions and levers to achieve Goal 4

water resources caused by past and current mining activities. (Macklin et al. 2023). An increase in mining and processing activities is raising concerns about the unintended environmental, social, and economic consequences that can potentially jeopardize the equitable benefits of the energy transition across countries. Mining and processing activities pose serious threats to ecosystems and biodiversity in several regions. In 2019, about 80 per cent of global metal extraction occurred in most species-rich biomes (Sonter et al. 2020; Luckeneder et al. 2021), causing irreparable ecological damage and biodiversity loss. For example, in Eastern Brazil, over 30 per cent of the habitat for bird or frog species is directly or indirectly affected by mining (de Castro Pena et al. 2017), with a potential ripple effect on the region's biodiversity. In Brazil and Colombia, significant loss in biodiversity has been observed (Siqueira-Gay et. Al. 2020; Ruiz-Agudelo et. al. 2025). Globally, at least 54 per cent per cent of energy transition minerals projects – involving upstream and midstream activities – are located on or near Indigenous Peoples' territories. (Salvador et al. 2020; Owen et al. 2023). Indigenous Peoples, as well as local communities play a significant role in global biodiversity conservation, while mining projects and infrastructure threaten their biocultural diversity through ongoing rights infringements and environmental injustices that affect their populations and their territories (United Nations, 1948; United Nations 2007; Owen et al. 2023).

Mining and processing activities are very water-intensive, leading to irreparable damage to freshwater resources. Many mines around the world are also situated in or near areas facing severe water stress (Kunz 2020). The effluents from mining and processing facilities frequently pollute water sources, posing significant risks to the environment and human health (IEA 2022d). In numerous other regions, mining activities have caused surface and groundwater depletion, contamination, and land degradation. For example, in the Loess Plateau mining area of China, data from 2017 and 2019 indicate an average decrease of 8.66 g of soil organic matter per kilogram of soil (Wang et al. 2021), which is crucial for biological functions in agricultural lands (Zhang et al. 2023).

The mining and processing activities are also energy-intensive, relying heavily on fossil fuels. The mining sector alone accounts for approximately 1.7 per cent of global final energy consumption (Aramendia et al. 2023). Fossil fuels have accounted for 70 per cent of the energy used in the sector's operations (United States Department of Energy 2007), with average CO_2 equivalent emissions from the industry ranging from 4.6 tons per ton of copper to 75.8 tons per ton of neodymium oxide (IEA 2023e). Among

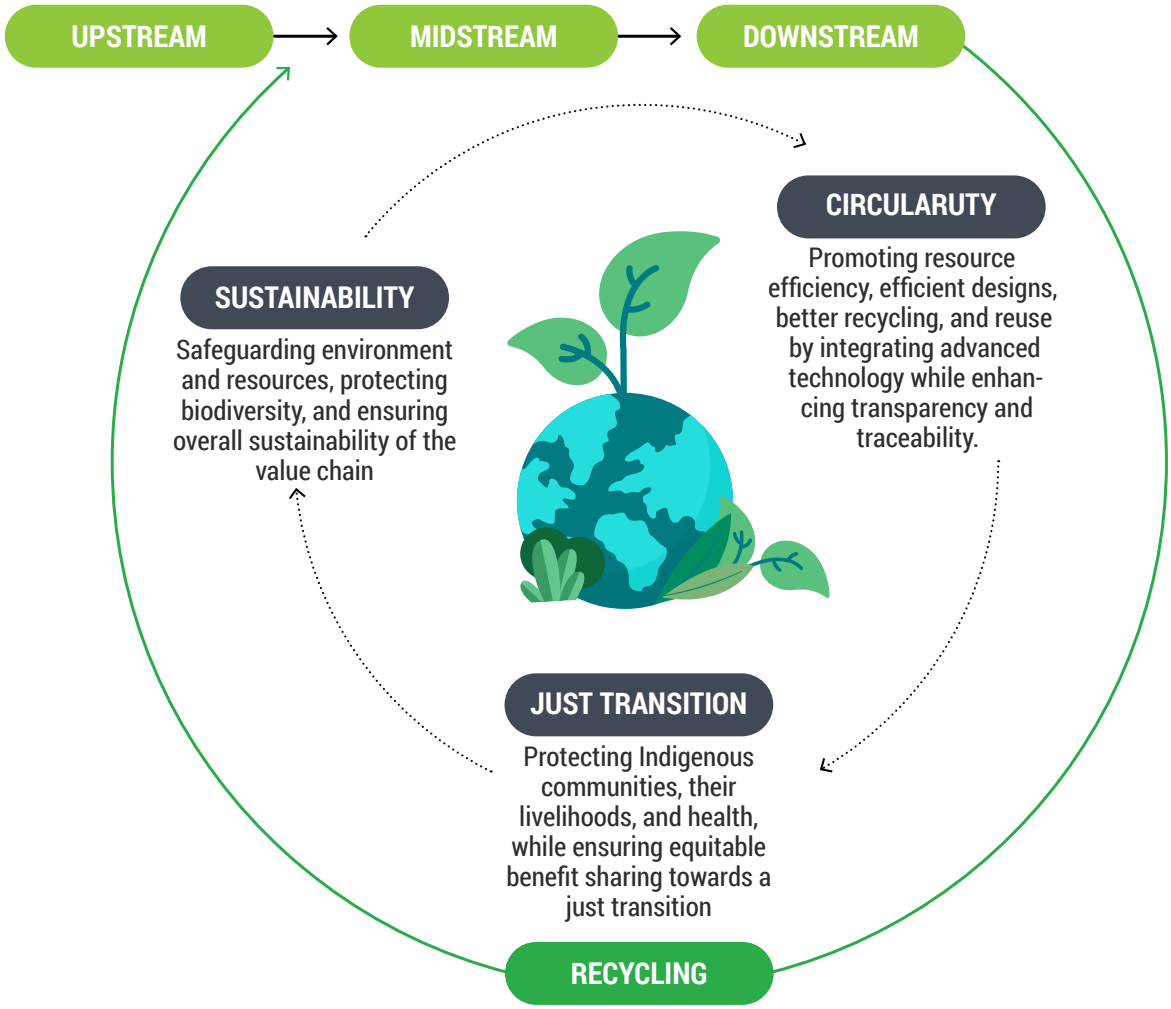
the top 10 countries with the largest GHG emissions from their mineral material sector, China tops the list (Zheng et al. 2023).

16.2.4.2 Solutions for improving the circularity of the critical energy transition metal sector

In the CETM sector, the inefficient use of materials and unregulated waste disposal exacerbate the challenges and damage the environment (UNDP 2016; IEA 2022d). Integrating circularity into CETM industry practices can reduce the emissions related to the extraction of various minerals (Babbitt et al. 2021; Safarzynska, Di Domenico and Raberto 2023; Toledano, Brauch and Arnold 2023; UNEP 2024b). Circularity needs to be built into every aspect of the value chain, from material energy requirements for mining to waste processing, requiring careful planning. Examples such as the European Union initiatives on battery recycling (European Commission 2023a) and the OECD Due Diligence Guidance (2018) illustrate promising approaches. Additionally, as technology evolves, emerging technologies are also likely to be less mineral intensive.

Another effective way to reduce the environmental footprint of the CETM sector is to promote urban mining and maximize recycling of minerals. While the current recycling rate for several minerals is very low, recycling can help meet a significant portion of the demand. Efficient recycling methods could supply up to 20 per cent of the total mineral demand between 2022 and 2050. (WWF 2022).

New and advanced technologies are needed to enhance the circularity of the CETM sector. While some industry players are adopting several technology changes, including electrification and energy-efficient practices (Mining Technology 2022), broader implementation is needed. Further, to track circularity and sustainability practices in the CETM value chain, advanced digital technologies, such as blockchain (Calvão and Archer 2021; IEA 2023f; Meier, Gruchmann, and Ivanov 2023), can play a crucial role. Blockchain can provide transparency, ensuring adherence to sustainability and equity standards and helps prevent black market activities (Calvão and Archer 2021). Additionally, standardizing national databases for the exchange of information across the value chain is essential for informing policy decisions.



Finally, promoting circularity will also foster innovation in advanced technologies, which can help develop applications that are less mineral intensive. As the clean energy transition accelerates, there may be substantial demand for opening new mining and processing sites. Mining in unexplored and sensitive areas, especially ocean ecosystems, can have far-reaching and negative consequences. (Levin, Amon, Lily 2020). In 2024, Norway approved commercial deep-sea mining despite concerns from the international community about its potential unintended consequences (Nature 2024). Global mechanisms, including the United Nations Convention on the Law of the Sea, can present a negotiating space through which these mining initiatives can be litigated and potentially banned.

16.2.4.3 Solutions to reduce the environmental aspects of the critical energy transition minerals sector

Responsible mining and processing activities, along with effective waste management, are crucial for reducing environmental damage. Programmes such as the Climate Smart Mining Initiative (Hund et al. 2020) can assist mineral-rich countries in minimizing social, environmental, and climate impacts. For instance, policies could be implemented to strictly regulate mining and processing activities in medium-high to extreme water-stressed areas. Existing and new mining could also be heavily restricted in regions of high biodiversity or cultural value. For example, governments could restrict mining within any of the categories of land areas classified by the International Union for Conservation of Nature as in most need of conservation (International Union for Conservation of Nature [IUCN] 2013) or protected under any international institutions' directives, such as heritage sites (Turner 2012).

Since mining is energy-intensive, the CETM industry could be encouraged to adopt renewable energy sources. Integrating renewable energy at their sites could help improve energy access for rural populations, Indigenous Peoples, as well as local communities. In some cases, stricter environmental regulations can also enhance the financial performance of mining and processing companies by reducing the risk of lawsuits, fines and costly remediation. In 2018, the sector faced over US$20 billion in financial impacts due to litigation, development of new water sources,

Figure 16.9: Core Principles of a responsible CETM value chain

contamination management, and other issues (Carbon Disclosure Project 2018).

16.2.4.4 Solutions to promote transparency and improve governance

Mining causes disruption, especially for Indigenous Peoples and local communities (Janardhanan et al. 2023; Bebbington and Humphreys 2018). Human rights-based solutions can play a critical role in protecting communities, especially in high-risk situations (Lèbre et al. 2020). Recognizing the rights and sovereignty of Indigenous Peoples can also improve outcomes through more equitable engagement in negotiations, assessments and increased agency in whether and when to engage with mining companies (Horowitz et al. 2018). Protecting Indigenous Peoples' well-being, including their cultural identities, is supported by adhering to the right to free, prior, and informed consent (Owen et al. 2022; Burton et al. 2024) (well established).

Adequate finances are necessary to promote and incentivize sustainable mining and processing practices, with developed countries playing a leading role through the creation of a "green mineral fund". A global fund with a dedicated dividend mechanism could help to scale these efforts (Intergovernmental Forum on Mining, Minerals, Metals and Sustainable Development 2024). Such a fund could provide compensation to communities in resource-rich developing countries while encouraging sustainable practices. Governments and industries can jointly agree on the fund's design under the oversight of a multilateral institution. Examples of such funds include the Alaska Permanent Fund (International Labour Organization [ILO] 2002) and Mongolia's Sovereign Wealth Fund (World Bank 2021). Resources for a Green Mineral Fund can be generated from

Credit: FastSpeedsImagery/Envato

the private sector, end-user companies, or through a tax on advanced technology-based equipment or machinery exceeding a certain price threshold. These funds can then be used to finance sustainable mining in developing countries or support communities displaced or affected by mining. However, to prevent such a premium from hindering the energy transition, multiple tax bands can also be introduced based on technologies, ranging from essential to luxury. Elements such as product traceability, recyclability, and transparency can also be considered for categorizing into tax bands. This approach can further promote benefit-sharing (UNEP 2024b), especially through active participation and compensation of Indigenous Peoples (Government of Canada 2022).

Promoting transparency and strengthening governance in CETM value chain requires strong standards and effective traceability systems. Traceability involves the physical tracking of mineral resources at each point of trade (OECD 2016), supporting circularity and preventing illegal mineral flows. Certification and tracking methods will increase transparency and address due diligence concerns within the global market.

Several existing examples, such as Canada's Critical Mineral Traceability Project, Conflict-Free Sourcing Initiative, Alliance for Responsible Miners, and OECD due diligence guidance for responsible mineral value chains, are some of the notable initiatives. Adoption and strict adherence to Environmental, Social, and Governance criteria for licensing companies to operate would also increase their willingness to invest in and adopt these technologies. Additionally, developing a comprehensive global database that covers all activities, promoting the research and development of technologies, and establishing an international governing system.

Box 16.1 Equity and justice in the energy transition

Furthermore, paying closer attention to gendered experiences and values could lower risks for women during the energy transitions (Dudka 2024). Incorporating gender analysis can enhance the development of alternative pathways for health, safety, community development, and energy systems, ensuring gender-inclusive representation and benefit distribution (Tsagkari 2022). For instance, ensuring that women have equal access to resources, training, and decision-making opportunities is vital for the success of these pathways.

Placing equity and justice at the centre of these solution pathways highlights that many energy transformation projects face opposition and contested debate around the real and perceived trade-offs. This opposition stems partly from historically and presently marginalized communities, at local to global scales, who are excluded from decision-making that affects their lives. For instance, pipelines in North America cut through land owned by Indigenous Peoples or land that was inappropriately expropriated through colonialism (Spice 2018; Hurlbert and Datta 2022; Gobby et al. 2022). Due to systemic marginalization, these communities may occupy land considered of lower value, and thus, from a government perspective, an attractive place for new energy infrastructure. Policies that promote Indigenous Peoples' active involvement in rights-based, equitable, culturally safe, and community-led participatory processes in energy projects are essential to honour Indigenous Peoples as leaders, rights holders, and knowledge keepers, and to prepare future Indigenous leaders (GEO-7 IK&LK Dialogues 2025). Policies respecting Indigenous territorial rights and legal frameworks, enabling self-management of resources, supporting community-led environmental monitoring, safeguarding labour rights, and ensuring fair revenue distribution can help reduce inequities in the mineral value chain.

Recognizing that energy transformations unfold within already affected and inequitable spaces can provide a point of departure for considering how to address and redress existing injustices, including co-ownership, revenue sharing, and adherence to free, prior and informed consent principles. Self-determination – guided by the principles of free, prior, and informed consent – supports the equitable distribution of benefits from mining and land use for Indigenous Peoples.

Energy sovereignty is also a key factor in ensuring access to clean and affordable energy, promoting self-governance by Indigenous Peoples, and supporting emission reduction efforts. Energy sovereignty initiatives for Indigenous Peoples require safeguarding and implementation in regional, national and local policies through international instruments such as ILO 169/UNDRIP.

Large-scale deployment of land-intensive energy sources and mitigation options such as BECCS can perpetuate inequities (Fyson et al. 2020). Disputes can also arise when exclusion is perceived or when benefits are not shared equally. Certain interventions may shift power dynamics within communities, leading to further exclusion of already marginalized groups, including older adults, people with visible or invisible disabilities, or those affected by income differences. This also spans generations, recognizing that establishing more just processes and structures now is a vital part of ensuring intergenerational equity. An increasing number of indicators are being developed to operationalize this idea and enhance the ability to monitor progress (Kime et al. 2023).

16.3 Combination of solutions to achieve the desired goals

The solutions outlined in the previous section contribute to achieving sustainable and equitable energy for all. However, realizing system-wide transformation in the coming decades requires these solutions to be combined and tailored to specific contexts. These solutions are interconnected and can serve a different purpose depending on the strategy adopted. For example, the scale of zero-carbon energy required will partly depend on the growth in energy demand and the reliance on CDR, while lower energy demand and higher energy efficiency will reduce dependence on CDR (Grubler et al. 2018).

Energy system transformation strategies will vary across countries and regions and are shaped by a wide variety of factors and contexts that go beyond economic and technological dimensions. As highlighted in different parts of the chapter, sociocultural, environmental, geophysical and institutional dimensions are also important. These six dimensions are framed within IPCC's Multidimensional Feasibility Assessment and help assess actions through different lens. Such lenses include resource endowments, trade and integration with other countries and regions, carbon sequestration potential, public acceptability of various technologies, the nature of domestic industries, and the degree of urbanization. As well the relationships with other societal priorities such as energy access, energy security, air pollution, and economic competitiveness were examined (IPCC 2022c, 2022d).

As such, the levers and solutions provided in the Goals-Solutions-Levers (GSL) diagrams should be understood as strongly supported by the literature and generally applicable, but they are not exhaustive (IPCC 2023a). Effective approaches must be tailored to local circumstances, utilizing a combination of regulatory tools, funding mechanisms, and training programmes. The best strategies need to be regionally customized and culturally appropriate.

16.3.1 Governance across solution pathways

National governments play a critical role in establishing the regulatory and fiscal landscape that guides decision-making of subnational entities, the private sector, and households. Importantly, they can set in place a credible, coherent set of policies and long-term strategies (Averchenkova, Fankhauser and Finnegan 2021).

In the near term, governments can take a range of integrated actions to accelerate transitions, including:

- Support both market and non-market structures, such as energy communities to reduce energy poverty
- Align trade and investment practices to promote the regional integration of transmission grids and renewable energy
- Apply stricter minimum energy performance standards and upgrade infrastructure
- Establish environmental policies and rights-based approaches to ensure that emerging technologies and activities, such as mining, do not reinforce inequities

Governments can develop policy measures to support energy transitions to low-carbon systems by using various domestic governance and regulation tools, including market-based instruments such as carbon taxes, emission trading schemes, fuel standards, and energy efficiency codes (Eskander and Fankhauser 2020). For instance, China's and the European Union's emission trading schemes have extensive coverage across sectors and regions and their histories offer valuable insights into how to enhance the effectiveness of these systems (Stoerk, Dudek and Yang 2019; Bruninx, Ovaere and Delarue 2020). Other regulatory approaches have also been implemented to support decarbonization, including renewable energy and energy efficiency standards, using tax codes to encourage the purchase of low-carbon technologies such as heat pumps and electric vehicles, subsidies for alternative energy sources, and research and development subsidies (Cabeza et al. 2022). Recent evidence shows that a combination of these tools is most effective (Stechemesser et al. 2024).

Laws, regulatory approaches, and other methods to align policies can be sequenced to achieve the high

levels of stringency. However, since some policies may face greater public opposition or other barriers, intentional and strategic planning about these barriers and ways to overcome them should be integrated into policy design (Pahle et al. 2018). This planning must also align with public and national priorities and contexts (Drews et al. 2016). As transformations require establishing structures that can push incremental changes into lasting ones, signals from governments demonstrating credible commitments to the long-term goals of decarbonization can play a critical role.

Broad-based framework laws that are working include the UK Climate Act (OECD 2021), and other variants including Korea's Framework Act on Low Carbon, Green Growth, Kenya's Climate Change Framework, and Mexico's General Law on Climate Change. Such framework laws can establish the structures, responsibilities, and accountability necessary for reaching climate goals and provide the legal foundation for systemic change (IPCC 2022b).

Legislative frameworks and policies that focus solely on decarbonization, however, may be more vulnerable to political backsliding, especially as they involve trade-offs with other objectives and can be more difficult in contexts with a high reliance on fossil fuels. Therefore, more systemic, economy-wide approaches can be truly transformative, such as Green New Deal-style strategies (Boyle et al. 2021) that address complex drivers and barriers, such as macroeconomic and fiscal constraints. Ensuring broad support requires attention to the distributional aspects and the contextual nature of these changes (McCauley and Heffron 2018; Roberts et al. 2018). Just-transition frameworks that emphasize fairness, participatory processes, and preservation of livelihoods and social protection, especially for the most vulnerable groups, can play a key role in accelerating these changes (McCauley and Heffron 2018).

While national and subnational governments implement many solutions to environmental issues caused by development, this can lead to problems related to national capacity and the social and political contexts of any given location. Such issues can result in significant political feasibility gaps. For example, even if policies are adopted, they may not be enforced or enforceable, and may create new opportunities for elite capture and corruption, potentially exposing communities to harm in the name of environmental protection. Political commitment to transparency, oversight, and anti-corruption measures can address these risks (Cloke, Mohr and Brown 2017).

16.3.2 Individual and collective action across solution pathways

Engaging diverse actors is essential in all aspects of energy transformation. Governments are responsible for creating supportive environments for change, but the private sector, scientists, communities, households, and individuals also play vital roles. Building societal support involves both providing information and enhancing empowerment and equity throughout the transition process. Processes that ensure all voices are heard, especially those rooted in equity and justice, are crucial for achieving transformative outcomes and lay the groundwork for addressing distributional challenges, including the risk of increasing inequality (Ahlborg 2017). Diverse values, worldviews, voices and perspectives, including Indigenous Knowledge and Local Knowledge, must be given space to contribute to planning and implementation of the various actions outlined above, such as through participatory governance, self-determination, and reconciliation. Creating these conditions may require addressing past inequities and injustices, emphasizing human rights-based approaches. All voices should be heard, and as a recognized by the SDGs, no one should be left behind.

16.3.3 Economics and finance across solution pathways

Finance – particularly its availability and accessibility – serves as a vital enabler for climate action and the energy transition by encouraging investment in new projects and locations. It also involves directing support to communities and other locally led initiatives. Additionally, it helps shape the financial incentives surrounding investment across all solution pathways. Enhancing access to finance, creating new sources like green bonds designated for energy investments, and implementing innovative pricing, including domestic and international carbon pricing, can help stimulate investments. This can be complemented by public-private finance and other de-risking strategies to reduce capital costs. Structural changes, such as relocating industries with high energy consumption, and aligning development and climate policies, may also promote long-term transformations (Calcaterra et al. 2024).

Climate policy is increasingly shifting focus beyond emissions reduction to addressing the root causes of fossil-fuel production. This brings greater attention to fossil-fuel subsidies (Skovgaard and van Asselt 2019) and underscores the need for careful evaluation of both direct and indirect effects. Effective climate and energy transition policies, such as carbon pricing, must account for subsidies as well as cover the entire fossil-fuel value chain.

Developing a policy framework for an orderly transition from fossil fuels requires acknowledging the unequal challenges faced by countries, especially those with high fossil-fuel dependency, and the need for financial support to facilitate these transitions (Newell, Van Asselt, and Daley 2022). Identifying and phasing out subsidies – both direct subsidies such as undercharging for supply costs and indirect fossil-fuel subsidies such as undercharging for environmental damages and external costs such as pollution – can support the energy transition by improving macroeconomic performance and creating fiscal space for stable renewable energy investment (Monasterolo 2019; Kamali Saraji and Streimikiene 2023; WEF 2023a). However, coordination with other policy tools that support clean energy is required to meet deep decarbonization goals (Schwanitz et al. 2014; Belfiori 2021)

Global fossil fuel subsidies continue to pose a major obstacle to decarbonization and are at record levels (WEF 2023a; IEA 2025a). In 2022, fossil-fuel subsidies hit a historic US$7 trillion worldwide, equal to 7.1 per cent of global GDP.

However, reforming these subsidies is politically challenging due to their integration into national economic policies and the benefits they provide to existing industries and consumers (Skovgaard and Asselt 2019). Effective reform requires tailoring measures to specific political and economic settings (Mahdavi, Martinez-Alvarez and Ross 2022). Repurposing subsidy savings may also be difficult; however, redirecting these funds to help lower-income populations manage costs can offer crucial social support during the transition (Malerba 2023). Such support has shown to be particularly vital for effectiveness in low-income contexts (Kyle 2018).

The costs of inaction are higher than the costs of mitigation for pathways that achieve 2°C (Riahi et al. 2022).. Economic instruments have proven effective in regulatory settings, including approaches to internalize damages such as the social cost of carbon.

Incorporating the social cost of carbon, which estimates economic damages caused by emitting one additional ton of carbon dioxide, into regulatory cost-benefit analysis helps support decarbonization policies (Nordhaus 2017). Although the development and use of the social cost of carbon have been debated, recent estimates and its application in several countries – including the United States, Canada, France, Germany, and the The United Kingdom of Great Britain and Northern Ireland – have reinforced its value (IPCC 2022b). Moreover, the latest estimates likely underestimate the true damages, suggesting that more stringent decarbonization may be justified (IPCC 2022b).

16.3.4 Science and technology across all solution pathways

The technological pathways above also highlight the need for substantial innovation in new fuels, processes and technologies, especially those required for CDR (Blanco et al. 2022). To achieve this, research and development policies must complement pricing policies and other legislative commitments. Targeted subsidies for research and development have been shown to enhance innovation at the firm level (Stucki et al. 2018; Bai et al. 2019). Strengthening research and development capabilities across universities and industries can serve as vital levers in promoting new technologies. in promoting new technologies.

The deployment of digital technologies in energy sectors seems to be a promising way to support these innovations. Including smart grids and digital governance systems can improve operational efficiency, while enhancing resource management and energy trading (Mahmood et al. 2024). This aligns with ongoing sector changes that aim not only to meet carbon reduction goals but also to boost economic resilience and sustainability in energy supplies.

Research is also necessary beyond technological innovations. Social contexts are not yet fully understood in all geographical regions. While understanding that solutions depend on the context is commonly accepted, knowledge gaps remain. Ongoing research on behaviour and emotions influencing climate responses can enhance

Credit: YanMednis/Envato

understanding of perceptions and expectations. More research is still needed on governance, shifting power dynamics within decision-making, and the contributions of Indigenous Peoples and Indigenous Knowledge in guiding behavioural change.

16.3.5 Capacity-building across all solution pathways

A clear need exists across all pathways for capacity-building at all levels, with workforce development being essential for deployment. More energy technicians are needed in various fields, such as installing and maintaining heat pumps and solar energy systems, both stand-alone and as part of distributed generation systems. Local planners also require training to design compact urban spaces that consider sociocultural contexts while prioritizing inclusion and accessibility.

This can be achieved by working more closely with professional societies and unions, as well as in rural areas, by integrating these topics into school curricula and offering training programmes in other languages, including Indigenous languages. Initiating these programmes early and ensuring they are customized to the needs of target audiences can facilitate the just transition. Collaboration across sectors and governance levels also requires capacity-building to improve cooperation and coordination of actions within energy systems and across different systems.

Box 16.1 Climate adaptation for energy systems

Climate change is resulting in increasing challenges to the energy system, underscoring the need for accelerating considerations for climate change adaptation. Parties to the United Nations Framework Convention on Climate Change acknowledge that different energy-generation systems have distinct vulnerabilities and varying needs to build resilience (United Nations Framework Convention on Climate Change (IPCC 2022a).

For example, hydropower capacity may decline due to increased drought (IPCC 2022b, Esquivel et al. 2016), with predictions of a significant per cent reduction in hydroelectricity generation in Costa Rica and Panamá in 2024 because of El Niño. Less specifically, flash floods and high winds can damage energy infrastructure, power lines through forested areas may face increased wildfire risks, and extreme heat can put greater demand on water supplies used for cooling and decrease the efficiency of solar panels. As well, storms and cyclones can trigger slope collapses that damage hydroelectric installations and severely impact local communities (IEA 2020, IPCC 2022c).

Providing reliable electricity is a crucial component of climate adaptation (Davide, De Cian and Bernigaud 2019). Increased resilience can be achieved through backup systems, multiple storage systems, and smart grid technology, as well as by updating and improving construction standards, strengthening infrastructure assets, and diversifying energy sources (IPCC 2022a). Importantly, early warning systems can be powered by more reliable energy sources.

Energy systems were included in the IPCC's WGII assessment for the first time in the Sixth Assessment Report, highlighting their vulnerability but also underscoring the vital role of energy in adaptation – both directly and as an enabler of other options. Considerations for adaptation are also crucial, as some mitigation strategies may increase the vulnerability of ecosystems and communities, such as through BECCS and the mining of CETMs. Similarly, stringent mitigation strategies are critical for ensuring that energy use for adaptation does not lead to increases in emissions (Colelli 2022).

Therefore, using analytical tools such as multidimensional feasibility assessments can be helpful, as they enable the evaluation of synergies and trade-offs among mitigation and adaptation options.

16.4 Case studies

Two comparative case studies highlight the importance of engaging multiple and diverse groups, providing appropriate incentives, and applying an equity lens to create lasting change, while also emphasizing the significance of context. These case studies further demonstrate that the ability to respond to unexpected shocks with prompt, feasible, and suitable actions can open a window of opportunity for rapid shifts that might otherwise have faced significant barriers.

16.4.1 Case study 1: Heat Pump Installation

Heat pumps are widely recognized as a cornerstone technology for decarbonizing the building sector (Rosenow et al. 2022). This case study assesses its deployment and diffusion, highlighting contextual factors that enabled or created barriers.

Heat pumps hold tremendous promise as they are three to five times more efficient at heating buildings than conventional gas furnaces or boilers (IEA 2022a).

One misconception about heat pumps is that they only work in temperate climates, but newer models have been shown to work in extremely cold conditions such as Alaska (Gibb et al. 2023, Crownhart 2023). Moreover, they can be retrofitted onto existing heating systems to use conventional radiators and underfloor heating systems. Another benefit is that they can be used for cooling as well as heating, and cooling needs are rapidly increasing worldwide with climate change. existing heating systems to use conventional radiators and underfloor heating systems. Another benefit is that they can be used for cooling as well as heating, and cooling needs are rapidly increasing worldwide with climate change.

Rolling out heat pumps on a massive scale can be challenging. Specifically, not enough engineers are trained to install and maintain heat pumps. Providing the public with reliable and easy-to-access information about the financial and energy advantages of heat pumps will promote adoption by households.

Ground-source heat pumps cost more to install because they require digging, but they are more efficient and better suited for larger buildings. Air-source heat pumps are similar in shape and size to outdoor air conditioners and are used for both heating and cooling.

Government-supported transitions to heat pumps can evolve for varied reasons. The European Union responded to the war in Ukraine by sanctions on the export of natural gas and oil from the Russian Federation. This change has affected access to natural gas in Europe and may be encouraging a long-term shift away from natural gas. Of all the natural gas used in Europe, one-third is used to heat buildings (IEA 2022a). Generally, space heating and cooling account for 50 per cent of building energy use (European Commission 2023b). The European Union has enacted several laws to promote heat pumps, including the Fit-for-55 climate strategy (European Commission 2021) and REPowerEU (European Commission 2022), which can help reduce energy demand and facilitate a fair and just transition by prioritizing investments in renewables and energy efficiency. Member states are also encouraged to phase out subsidies for fossil-fuel boilers (Adamo et al. 2024).

In 2022, the global sales of heat pumps grew by 11 per cent (IEA 2023a). In Europe, the sales grew by 40 per cent to more than 3 million units. Air-to-water models have been particularly popular as they are compatible with older heating systems. The European Union plans to have an additional 10 million heat pumps installed by 2027 (European Commission 2023b).

Linked with government energy security concerns and climate commitments, heat pumps have been at the forefront of the energy transition. In addition to heating and cooling, heat pumps can also be used for water heating, which is often another large energy end-use in buildings.

As electric appliances, heat pumps can strain local power grids during peak demand on cold days. To address this, promoting weatherization programmes to retrofit buildings and therefore lower energy demand is important, alongside efforts to decarbonize regional power grids. While the energy transition unfolds amid ongoing disruptions and geopolitical tensions, recognizing that this is an evolving context is highly relevant. Seizing emerging opportunities and implementing options that foster resilience to future disruptions will be key to successful transformations.

16.4.2 Case Study 2: Renewable Energy Communities

Community-scale renewable energy generation, unlike a top-down approach typical for utility-scale plants, can better reflect user priorities and equitable gender representation (Bauwens and Devine-Wright 2018; Berka and Creamer 2018). Renewable energy communities are increasingly viewed as an alternative to grid connection, providing a transformational process centred on the community's priorities (Gui and MacGill 2018). As such, this approach can play a crucial role in facilitating just transitions (Hoicka et al. 2021). Local governance of these systems offers opportunities for broader social transformations. This can be especially important in low and middle-income contexts (Cloke, Mohr and Brown 2017) and Indigenous communities (Velasco-Herrejón, Bauwens and Calisto Friant 2022).

Depending on the context, energy communities can engage and protect community needs, thereby promoting inclusion and reducing barriers to adoption (Noll, Dawes and Rai 2014; Koirala et al. 2016). While there are various models for energy communities, fundamentally, they are

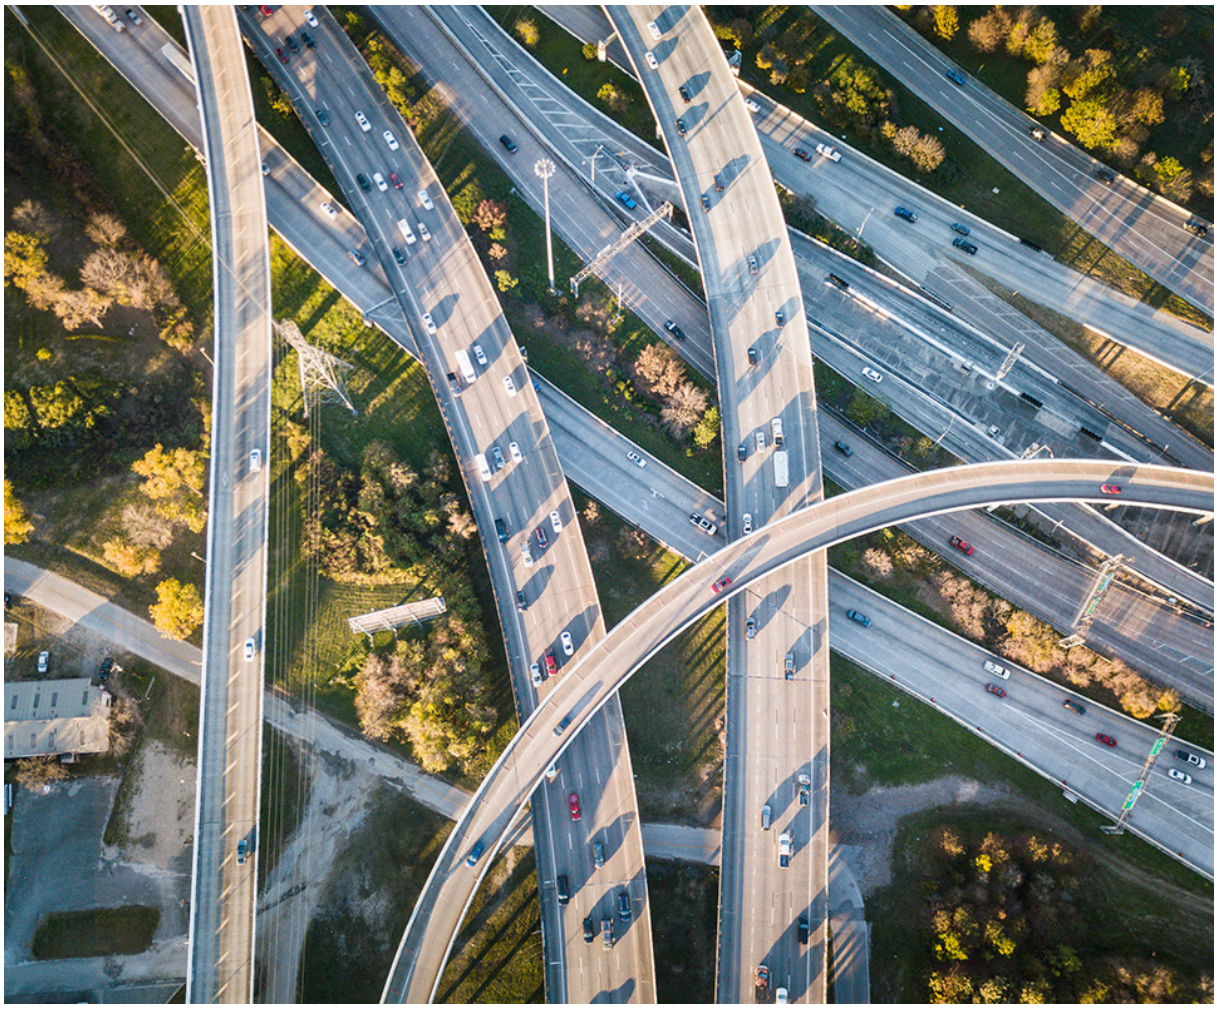
projects owned by or heavily involving the community, with communities participating in the production and use of sustainable energy (IRENA Coalition for Action 2018). Examples of energy communities now exist in both developed and developing countries, with many communities pursuing ambitious visions of sustainable and renewable energy (Seyfang, Park and Smith 2013; Van Der Schoor and Scholtens 2015).

However, it is essential to acknowledge the differences in conceptualization and execution between developed and developing countries (Okem and Ley 2023). Examples include use of solar panels in favelas in Brazil (Abraham 2023), solar-projects in India (Joshi and Yanneti 2020), numerous projects and networks in Europe (Santos 2023), shared solar energy in the United States of America, (Grimley et al. 2022), and Indigenous-led projects in Canada (Indigenous Clean Energy 2023). But in some examples, such as in Spain, this scheme is only for higher-income families, and excludes lower-income people who can't afford to buy into the scheme (Okem and Ley 2023). These decentralized models have several advantages over the top-down approach, including building strong communities, reducing payback periods and energy costs, and supporting sustainable policies from local to national scales (Klein and Coffey 2016). These efforts also have benefits for climate adaptation by building resilience of the energy systems and communities (Sapkota et al. 2014).

Scaling up renewable energy communities requires collaboration among multiple actors including communities, governments, the private sector, and researchers. Governments play a key enabling role by creating opportunities that support community-led efforts (Oteman, Wiering and Helderman 2014). As observed in the European Union, legislative frameworks were introduced to formalize and support community efforts, ensuring that large-scale developments do not dominate by default (Hoicka et al. 2021).

16.5 Implication of the solution pathways on the other systems

All systems have complex interdependencies, where achieving one goal can create synergies and trade-offs affecting other systems (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2024a). **Table 16.2** highlights the key interactions from energy solutions to these different systems, including food, environment, economy and circularity. It can serve as a foundation for a comprehensive evaluation of how to minimize trade-offs and enhance synergies (IPBES 2024a).



16.5.1 Food systems

Energy system transitions intersect with food systems in various ways. Access to energy directly supports food system transformation, especially through modern fuels that enhance food preparation and reduce demand for land and fuel production. Infrastructure development, like transmission grids and renewable energy generation, can contribute to land degradation or compete with agricultural land use (Nwaigwe, Mutabilwa, and Dintwa 2019; Candelise, Saccone and Vallino 2021; He et al. 2024). Nonetheless, innovations such as agrivoltaics provide co-benefits for both energy and agriculture, enabling the dual use of land.

Electrification can further enhance food production by increasing access to irrigation, which can boost agricultural productivity and farmers' incomes (Peters and Sievert 2016). Bioenergy applications also have mixed effects: while large-scale cultivation may compete with cropland and influence food supply and prices (Fujimori et al. 2022), targeted use of biochar can improve soil health and crop yields (Prütz et al. 2024). Reducing demand and increasing circularity in mining and other resource extraction can indirectly benefit the food system through pollution reduction and sustainable resource use, particularly for water.

16.5.2 Environmental systems

Electrification – particularly when combined with renewable energy sources – can significantly improve air quality and reduce health risks (Peng et al. 2018). There are strong co-benefits where climate mitigation policies that control air pollution emissions could reduce global warming by 0.5°C and save 2.4 million lives annually (Climate and Clean Air Coalition to Reduce Short-Lived Climate Pollutants 2014). Renewable-based microgrids and distributed generation can replace traditional biomass and diesel generators. The transition to modern, low-carbon fuels combined with the use of organic waste can lead to further improvements in air quality and health, as well as reduce GHG emissions from household energy use. Many renewable technologies also decrease water use compared to conventional power systems (Lohrmann

Credit: Daemaine/Envato

et al. 2019). Large-scale renewable deployment, such as hydropower, and mineral mining for clean energy technology, can damage biodiversity and ecosystems if not planned properly (IRENA 2023; Sonter et al. 2020). Responsible infrastructure development and mining practices are crucial for protecting biodiversity, particularly within CETM value chains.

Water savings is an important measure to reduce emissions and increase resilience in the energy system transition. A more efficient water use, for example, for cooling of generation plants, independently of fuel source, can make energy generation more efficient while also being beneficial for the surrounding ecosystem. Water savings is also a measure for climate adaptation, however, water based adaptation options will significantly reduce their efficiency as we approach and surpass 2C (Schipper et al. 2022) and this will also affect the energy transition. Water use in the energy solution pathway will have an impact in other solution pathways as water is an element that cuts across different transitions (Schipper et al. 2022; Caretta et al. 2022, United Nations Environment Programme, United Nations Technology Centre and Network, United Nations Climate Change Technology Executive Committee, UNEP Copenhagen Climate Centre 2024). For example, water use for hydroelectric plants, independent of the scale, can affect agriculture, forests, and communities or other settlements that are downstream (Jiang, Zhang and Hou 2020; Lobo et al. 2025).

16.5.3 Circularity

The energy transition can reduce material demand, manage waste, and enhance system efficiency. Throughout the system, principles of the circular economy must be integrated to prevent trade-offs. For distributed energy systems, reusing and recycling components like batteries helps prevent environmental impacts. In sectors that are harder to decarbonize, circularity can decrease dependence on critical raw materials and boost overall resource efficiency (e.g., Kalundborg). Circular practices in the CETM value

chain, such as water recycling, waste reduction, and closed-loop systems, offer important opportunities to cut pollution, lower the need for new mining, and promote innovation. Transparency and traceability in supply chains can further strengthen circularity by supporting informed resource governance and encouraging long-term sustainability.

16.5.4 Economic systems

Microgrids and decentralized systems are cost-effective solutions when extending the national grid is financially or logistically unfeasible, as they can transform livelihoods and support education in rural areas. Modern fuels reduce household labour burdens and health costs and improve household resilience. Electrification further supports economic goals by enhancing education, health services, and local job creation. The shift to renewables and low-carbon energy sources can increase employment opportunities. These effects can be transformative when paired with suitable training and industrial policies, though extra support will be necessary to prevent economic disruptions, particularly in fossil fuel-dependent regions. Governance strategies, including the establishment of a mining fund to encourage sustainable mining practices, can promote more equitable, long-term economic benefits (Intergovernmental Forum on Mining, Minerals, Metals and Sustainable Development 2024). Channelling international finance sources, particularly from highly industrialized developed countries to low and middle-income economies can be transformative, enabling renewable energy infrastructure roll-out. As well, such channelling can produce broader development advantages, provided there is appropriate access, availability, implementation oversight and capacity development, along with mechanisms to facilitate this finance and stimulate investment.

Biodiversity loss can be worsened by actions taken during energy system transitions. Some measures that greatly cut emissions may cause, sometimes irreversible, ecosystem harm and biodiversity decline. However, considering environmental and biodiversity consequences in energy projects can create mutual

Table 16.1: Synergies and trade-offs with other systems

Energy Systems Solutions	Food Systems	Environmental Systems	Circularity	Economic Systems
Provide modern fuels to households for cooking (Goal 1)	Ý	Ý	Ý	Ý
Expansion of existing grid network and mini-grids (Goal 1)	Û	Ý	Û	indirect
Implement more compact land planning practices (Goal 2)	Ý	Û	indirect	indirect
Achieve diversified, reliable and resilient electrification of all sectors where feasible (Goal 3)	Ý	Ý	indirect	Ý
Decarbonize power generation transitioning away from fossil fuels (Goal 3)	Û	ß	ß	Û
Strengthen circularity in CETM value chain (Goal 4)	Ý	Ý	Ý	Ý

*Ý = generally positive direct effects; Û = mixed direct effects; ß = generally direct *negative, indirect effects are not included*

benefits. Evidence shows that certain actions, like nature-based solutions and some small-scale bioenergy, can be good for both climate change and biodiversity (IPBES 2024a). Given the interconnected nature of the drivers of the planetary crises society faces, responses must also be approached in an integrated manner. The IPBES Transformative Change Assessment (IPBES 2024a) highlights the structural changes that enable transformation, including shifting power dynamics and incorporating diverse values and worldviews that offer a different perspective on the relationship between humans and nature.

Addressing biodiversity loss goes beyond incorporating environmental and biodiversity concerns into project planning, it also involves valuing Indigenous Knowledge. For example, the IPBES Nexus Assessment highlights the cost savings, as as well as the reduction in trade-offs of a nexus approach, compared to siloed strategies, that recognizes the value of Indigenous Knowledge (IPBES 2024a). Addressing biodiversity considerations can also help achieve climate change adaptation goals, especially when Indigenous Knowledge and visions are included.

While renewable energy offers many benefits, it can still harm ecosystems and biodiversity if not developed with robust spatial planning or stakeholder consultations. Therefore, an integrated approach is essential. For example, hydroelectric plants, regardless of scale, can significantly disrupt watersheds while also benefiting reforestation efforts, supporting irrigation for crops, offering flood protection, and enhancing the water supply.

16.6 Conclusions

This chapter underscores the urgency for coordinated and equity-focused approaches to transforming the energy system. There is ample evidence to guide and start this transition, specifically that relying solely on technological fixes is not sufficient. Broader systematic changes in finance, economics, innovation, and capacity-building are necessary.

The energy transition will involve a combination of short-term actions and long-term structural changes. While some measures—such as deploying decentralized renewable energy—can begin straight away, others require sustained investments in research, institutional coordination, and innovation. A core aim of the energy solution pathway is to advance equity by addressing existing inequalities and injustices embedded in the current energy system and development paradigms (Keady et al. 2021). For example, creating policy space and international support for universal access to modern energy services in developing countries is both urgent and fundamental for energy transitions.

While national actions are the primary means through which carbon policy and systemic changes are implemented, the international arena, particularly through processes of the Framework Convention on Climate Change, offers a platform for government coordination. The decision at COP28, in the context of negotiations for the 2nd Global Stocktake, clearly emphasized global efforts to transition "…away from fossil fuels in energy systems in a just, orderly and equitable manner, accelerating action in this critical decade, so as to achieve net zero by 2050 in keeping with the science."

Achieving this transition will require mechanisms that support equitable decarbonization with transformative potential, including targeted financial support, technology transfer and capacity-building (IPCC 2022b). Transnational climate-social movements – advocating for climate justice and led by youth, Indigenous Peoples, women, labour, non-governmental organizations, and civil society – also play a crucial role by influencing these processes and challenging status quo approaches, and they are vital for meaningful transformation (Almeida 2019).

A systems-oriented approach is crucial (IPBES 2024b). For example, bioenergy is a particularly complex but strategically significant component of the energy transition. At small scales, bioenergy solutions – such as biogas or bioethanol – can enhance household energy access and reduce reliance on polluting cooking fuels. At larger scales, BECCS can contribute to CDR, helping to mitigate hard-to-abate emissions and address potential overshoot (IPCC 2022b; Smith et al. 2024). Nevertheless, large-scale bioenergy deployment must be carefully managed to prevent intensifying competition for land and negative effects on food security and biodiversity. Effective regulatory frameworks, participatory planning, and integrated land-use strategies are critical to balancing these risks.

Climate-resilient development can guide transformation by promoting equity, learning from diverse knowledges, including Indigenous Peoples, and local communities, generating shifts in behaviours and values, and reforming financial systems (IPCC 2022c; Eriksen et al. 2024). This approach places equitable development at the heart of climate action and can be especially critical when trade-offs arise.

While the increased energy demand from expanding access may seem to challenge decarbonization efforts, the IPCC Special Report on 1.5°C identified pathways that meet energy service demands when coupled with enhanced energy efficiency and accelerated electrification (IPCC 2018). Thus, critical support for Goal 3 comes from Goal 2 where consumption of energy is decreased.

However, hard-to-abate sectors, such as aviation, agriculture, shipping and industry, require shifts to low-carbon alternatives, alongside efforts to scale CDR technologies to compensate for residual emissions. Additionally, mitigation pathways that align not just with the temperature limits but with the commitment to sustainable development under the Paris Agreement face fewer challenges, rely less on CDR, and place less pressure on land and biodiversity (Smith et al. 2024, Soergel et al. 2024). Similarly, approaches that consider synergies and trade-offs, such as climate-resilient development pathways that address climate mitigation, climate adaptation and sustainable development simultaneously, can help reduce conflicts, increase cost efficiency, and improve the public acceptance.

From the analysis of solution pathways, four overarching goals emerge, each of which can be supported by a portfolio of policy levers, preconditions and actor-specific actions. These levers can be employed by various actors, including national governments, subnational entities, private sector, community organizations, scientists, and individuals. Using the feasibility assessment framework outlined by IPCC Working Group II and III enables a comprehensive evaluation of potential transition pathways (IPCC 2022c; IPCC 2023a).

While technological feasibility for decarbonization is generally high, particularly for scalable, mature technologies, feasibility must be considered across six interrelated dimensions: economic, environmental-ecological, geophysical, institutional, technological, and sociocultural (Singh et al. 2020). Certain levers especially those related to governance can influence multiple goals. Integrated policy design that aligns sectoral actions and anticipates synergies and trade-offs, is essential to maximize co-benefits and minimize unintended consequences.

It is vital to take action while systematically evaluating what works and how to accelerate successful initiatives. This chapter emphasizes that suitable top-down support can improve technical and financial effectiveness and help maintain infrastructure for more decentralized and community-led systems (Joshi and Yanneti 2020). There is also the need for more systematic assessment behind the diverse motivations of energy transitions and the distinction between place-based and non-place-based communities (Moroni et al. 2019). This includes further research in developing country contexts (Holstenkamp 2019; Van Der Schoor and Scholtens 2019) and on the outcomes of different ownership models to ensure the project benefits are distributed equitably (Berka and Creamer 2018)

Chapter summary

Credit: Ancapital/Envato

The current food system is environmentally and socially unsustainable. (*very well established*). Current food production and consumption are major drivers of climate change, biodiversity loss, land degradation, and pollution while, billions of people still lack access to sufficient nutritious food {17.1}.

An environmentally and socially sustainable food system can only be achieved through a transformation of the way foods are produced, consumed and traded (*well established*). Key goals for this transformation include close to zero loss of areas of high biodiversity importance by 2030 and a tenfold reduction in the species extinction rate by 2050, land degradation-neutrality by 2030, and elimination of unsustainable use of surface and ground water abstraction for agriculture and a reduction in nutrient leaching. They also cover halved greenhouse gas (GHG) emissions from food systems by 2050; sufficient space available for large-scale adoption of land-based renewable energy and other climate mitigation measures; and healthy, safe, affordable, accessible, and diverse food for all, with hunger ended by 2030, the rise in obesity and diet-related non-communicable diseases halted, and micronutrient deficiencies eradicated. Finally, the goals address fair treatment of workers throughout the food system, inclusion of Indigenous Peoples as well as local communities in decision-making, and resilience to shocks and stresses.

Five solution pathways have been identified to achieve the goals of the sustainable food system. Achieving each goal requires a combination of pathways with different approaches creating different trade-offs and synergies. All pathways require actions from a wide range of actors, including policymakers and regulators, non-governmental organizations, the food industry, the financial sector, farmers, researchers, communities, and individuals. The five pathways are shifting to healthy and sustainable consumption; improving crop, livestock and aquatic food production and land-use systems; reducing food loss and waste and making the food system more circular;

increasing the production and consumption of healthy and sustainable novel foods; and reforming and improving regulation of the food industry, market structure and trade {17.2}.

Achieving the internationally agreed environmental goals cannot be accomplished without changing how animal-sourced foods (ASF) are produced and consumed (*well established*). While in some setting ASF products have human nutrition and livelihood benefits, their production is a major contributor to environmental degradation. Production of ASF contributes about 60 per cent of all food-related GHG emissions, and about 14-20 per cent of all anthropogenic GHG emissions. High consumption of red and processed meat is linked to an increased risk of non-communicable diseases, such as cancer. At the same time, intensive livestock production poses risks of zoonotic diseases, infectious animal diseases, and antimicrobial resistance. Tens of billions of animals are raised and slaughtered annually, primarily in intensive farming systems {17.1; 17.2.1}.

Livestock's environmental footprint can be reduced by lowering overall demand for ASF and improving production practices (*well established*). Key strategies include improving the efficiency of livestock production practices, adopting regenerative practices including lower-intensity livestock production practices, improving animal feed to reduce GHG emissions, reducing food loss and waste, reforming subsidies and taxes, and encouraging dietary shifts towards more plant-based diets and alternative proteins. The scale and pace of change are currently too slow to meet environmental goals {17.2.1; 17.2.2}.

A shift toward healthy and sustainable diets is essential for addressing both environmental and public health challenges (*very well established*). This transition will require substantial reductions in overall ASF consumption, particularly in industrialized affluent countries, with potential for limited expansion in low-income communities affected by undernutrition. Diets should include fewer processed and ultra-processed foods and a diverse range of fresh and minimally processed foods, such as fruits, vegetables, legumes, nuts, and pulses, as well as reducing rates of over-consumption and consumer food waste. Without these changes, the environmental benefits of efficient food production technologies will be limited and negative health outcomes, such as obesity, could be exacerbated. The externalities from the global food system are estimated to be around US$20 trillion, comprising US$7 trillion in environmental costs and US$11 trillion in human health costs, which is approximately double the US$9 trillion spent on the food consumed {17.2.1; 17.4}.

Novel alternative proteins, including novel plant-based foods, cultivated meat, and fermentation-derived products, could replace conventional ASF, reducing GHG emissions, lowering land and water use and loss of biodiversity, but more research and investment is needed (*established but incomplete*). These alternative options could also reduce the risk of zoonotic disease emergence and spread, antimicrobial resistance, and animal welfare concerns. Uncertainty remains around the contribution, and possible negative effect, that these novel foods could provide and when, with acceptance and adoption at scale unlikely before 2030. Realizing the potential of alternative proteins to meet both health and sustainability goals requires greater public and private investment, along with a coordinated international research effort and regulatory adjustments. Research focus is needed to enhance the taste and texture, reduce costs, and assess the nutritional and social effects to increase consumer acceptance {17.2.4}.

Crop, livestock, and aquatic food production practices need to become more efficient, resilient, and sustainable (*very well established*). Promising approaches include developing high-yielding crop varieties and animal breeds with greater adaptability to local production conditions and tolerance to pests, diseases, and climate stressors – such as heat, drought, flooding and salinity – as well as improved resource use efficiency. These advancements need to be combined with environmentally sustainable intensification practices. Crucially, aligning both genetic innovations and management systems with local agroecological and production conditions is essential to ensure long-term resilience and productivity.

Adoption of nature-based solutions – such as regenerative practices, conservation agriculture, agroecological approaches including agroforestry, and organic agriculture – can provide benefits. Achieving biodiversity goals will require a combination of multifunctional land use, land conservation and sustainable intensification in agricultural areas, with Indigenous Knowledge and Local Knowledge playing a vital role {17.2.2}.

Credit: bilanol/Envato

Capture fisheries and aquaculture production provide a valuable source of nutrition but cause environmental damage without sustainable management measures (*well established*). Overfishing, species decline, and ecosystem disruption result from unsustainable fishing practices. At the same time, aquaculture generates additional pressure by using wild-caught fish for feed, as well as chemical and waste pollution. Effective regulation, enforcement, and improved practices should be supported by shifts in societal perceptions and market incentives for environmentally sustainable fisheries and aquaculture {17.1; 17.2.2}.

Dietary shifts must be supported by policy, as voluntary actions by the food industry and consumers are insufficient (*established but incomplete*). Voluntary changes, including shifts in consumer preferences, social norms and food environments, and food industry changes on how foods are formulated, marketed and the information provided to consumers, would support a shift to sustainable healthy diets. However, to achieve a sufficient dietary change to meet environmental goals supporting policies are required, including policies that ensure food prices more fully reflect the environmental and health outcome costs and greater regulation of food industry practices. Changes to production subsidies – US$1 trillion is currently provided globally in agricultural and US$35 billion in fisheries subsides – and imposition of consumer taxes and subsidies, can ensure food prices better reflect their true costs to society and encourage more healthy and sustainable consumption {17.2.1}.

Achieving a sustainable global food system requires moving away from pursuing the lowest-cost foods, which are often nutritionally poor and unsustainably produced (*established but incomplete*). There is an implicit assumption that lower food prices and increased supply benefit society by improving access to food for the poorest. Over the past 60 years, food production grew faster than the global population, resulting in 34 per cent more cereals produced per person in 2022 than in 1961, and food prices have declined in real terms. Yet, 700-800 million people remain undernourished and there are increasingly high rates of obesity in most countries, highlighting that delivering cheap food does not ensure equitable or healthy nutrition {17.2.1; 17.3}.

Making healthy and environmentally sustainable food affordable requires dealing with poverty (*established but incomplete*). Strengthening welfare and social safety nets is needed, particularly supporting groups that may be adversely affected by reforms, such as the true cost of food pricing. In combination such measures could reduce poverty and inequality {17.3}.

Reducing food losses, including food waste, across the food system would enhance food security and reduce environmental damage (*very well established*). Food waste occurring during retail and food service and at a household level accounts for a 19 per cent loss of available food, with additional loss during production or harvest, transport, storage, and processing. The current 30-40 per cent food system losses, worth US$1 trillion, can be reduced through combinations of behavioural and technical approaches at the farm, supply chain, retail and household levels. Where losses cannot be avoided, adopting circular approaches, including nutrient recycling of waste and by-product streams, can help minimize environmental impacts {17.2.3}.

Reforming the global food industry market and trade is needed, including diversifying agribusiness and food supply chains, and aligning private sector incentives with the societal outcomes (*established but incomplete*). Coordinated multinational policymaking is needed to regulate transnational corporations operating in the global food system. An enhanced role for local and regional food systems can enhance environmental and societal benefits {17.2.5}.

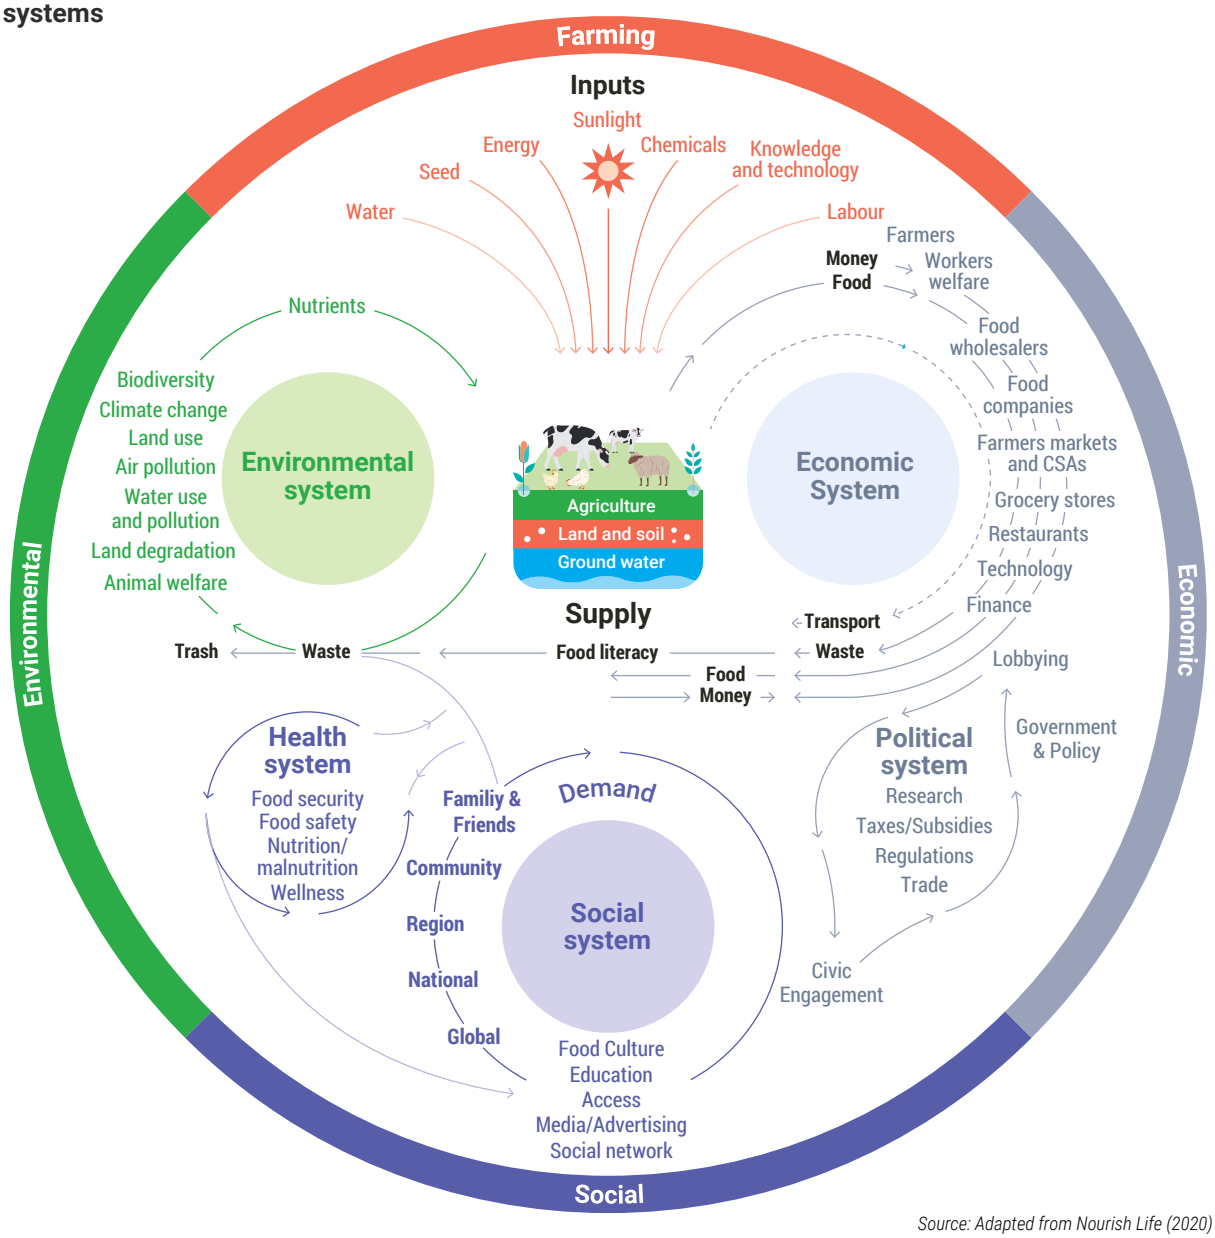
The food and financial sectors are central to funding the proposed food system transformation (*well established*). Access to financial capital is key for investment in alternative technologies, infrastructure, practices, and business models. Increased actions are required from the food industry to change practices, e.g., responsible sourcing, marketing, choice editing, portion sizes, labelling and reformulation to encourage healthier and more sustainable consumer behaviours {17.2.1; 17.2.2; 17.2.3}.

Shifting societal norms and consumer behaviour can be supported by community engagement and grassroots movements, including with Indigenous Peoples, along with education and awareness-raising targeted at changing preferences and values (*established but incomplete*). Public procurement of food can serve as a powerful tool to influence social norms and habits, promoting mindful, health-conscious and environmentally caring consumption {17.2.1; 17.2.2; 17.2.3}.

Expanding research and development and sharing of diverse forms of knowledge and data is necessary (*established but incomplete*). This includes advancing genetic research in crop, livestock, and aquatic systems, as well as strengthening the focus on Indigenous and local food systems, including locally adapted orphan and opportunity crops. Adopting locally adapted crop, livestock, and aquatic species helps in coping with environmental stresses while providing culturally appropriate food. Research and development of sustainable food systems, including novel technologies, data sharing, collaborative networks and partnerships, is necessary to accelerate innovation {17.2.2; 17.2.3; 17.2.4}.

Building skills and capacity across food systems is needed (*established but incomplete*). Public awareness and education on food, health, and environmental issues, as well as training and support for farmers, as well as veterinary and agricultural extension services, would support the required transformation. Retraining of displaced workers will also be needed with substantial shift away from livestock sector towards plant based foods or novel alternative proteins {17.2.2}.

Governance, policies and regulations set the conditions in which food systems operate, making policymakers and regulators critical to achieving the desired transformation (*very well established*). Key actions include reforming food and agricultural subsidies and taxation, removing perverse incentives and adjusting food prices to better reflect environmental and health externalities. They also should strengthen regulation of the food sector, including marketing (and especially marketing that targets children), choice editing, portion size and labelling; address market structure, including to control or breakup market power; and strengthen international regulatory coordination on transnational agri-food businesses and global food trade {17.2.1; 17.2.2; 17.2.3; 17.2.4; 17.2.5; 17.3}.



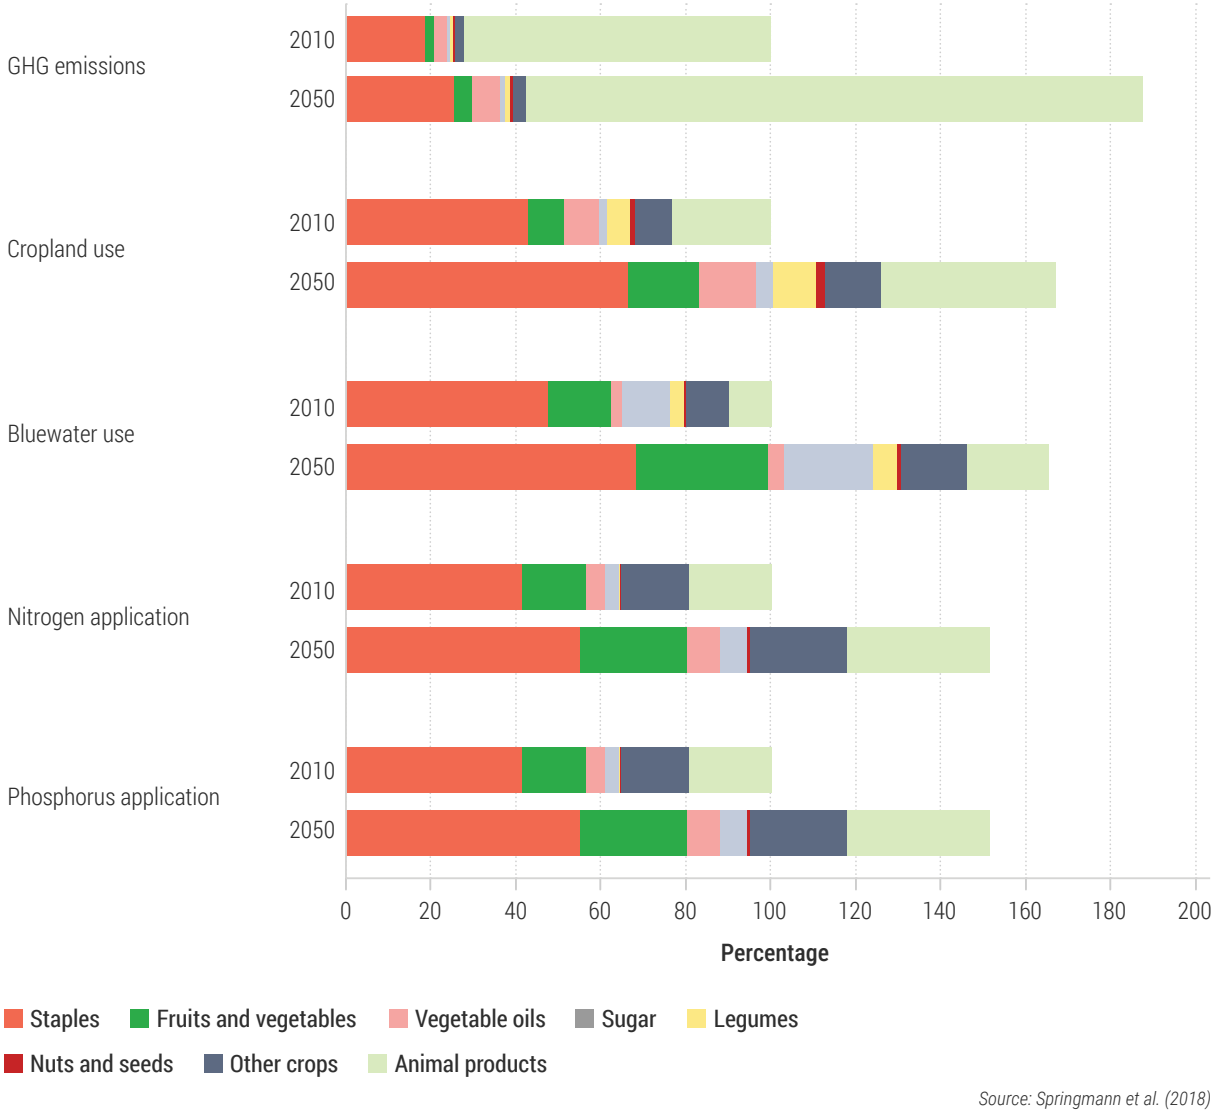
Connectivity among economic/finance, materials/waste, energy, environment and food systems means a successful transformation of all these systems can only be addressed together (*well established*). Changes to the economic system, including subsidy reform and pricing externalities, are central to achieving the food system transformation. Coordinated actions across systems is required due to competition for land with demands beyond food from renewable energy production, climate mitigation, biodiversity conservation and ecosystem functioning {17.4}.

17.1 Introduction

This chapter explores solution pathways for building a transformative food system, from food production to consumption, and back again, capturing the full cycle from "farm to fork". It examines necessary transformations – for crops, livestock, and fisheries – alongside dietary changes, including plant-based foods and novel alternative proteins. The chapter also highlights the key roles of governance, education, circular economic approaches, food distribution and marketing, all withing the context of adapting to environmental and social change.

The food system encompasses all the actors and activities related to the production, processing, distribution, trade, retail, preparation, consumption, and end of life management of foods and drinks, as well as the outcomes of these activities, including socioeconomic and environmental (High Level Panel of Experts [HLPE] 2017, p. 23) (**Figure 17.1**). Together, the activities undertaken by various actors across the food system give rise to the availability, access, affordability, utilization and stability of food with outcomes for food security (United Nations Environment Programme [UNEP] 2016). However, the current global food system fails to provide food security for all or end malnourishment in all forms, while creating substantial negative ecological and societal impacts that affect the achievement of many sustainable development goals (Willet et al. 2019).

Figure 17.1: Food System Map showing interactions between food consumption and supply, governed by the interactions of the social, political, economic and financial, and environmental systems



Source: Adapted from Nourish Life (2020)

The first quarter of the century has been characterized by lower food security, with four global food crises (2007-2008, 2011, 2020, 2022), albeit of varying intensity, reversing the long-term trend of hunger reduction (Webb et al. 2018).

The UN adopted the Sustainable Development Goals in September 2015, including SDG2: End hunger for all (Chapter 7). So far, there are few signs of meeting this goal, with 347 million adults globally underweight in 2022 (Phelps et al. 2024). In 2023, between 713 and 757 million people experienced hunger, approximately 152 million more than in 2019 (Food and Agriculture Organization [FAO], International Fund for Agricultural Development [IFAD], UNICEF, World Food Programme [WFP], World Health Organization [WHO] 2024), and 282 million people with acute food insecurity due to a combination of conflict, weather extremes and economic shocks (Global Network Against Food Crises 2024). The number of chronically undernourished people is projected to reach 582 million by 2030, with consequences including childhood stunting and wasting (FAO 2024). Additionally, 2 billion people worldwide suffer from micronutrient deficiencies – such as vitamin A, iron, iodine, and zinc – leading to various health problems.

All countries face at least one form of malnutrition. While undernutrition and hunger are most prevalent in low-income countries, particularly in South Asia and Sub-Saharan Africa, obesity and diet-related non-communicable diseases are rising globally (Popkin and Ng 2022). In 2022, 878 million adults were obese (Phelps et al. 2024). Diet-related non-communicable

Figure 17.2: Current (2010) and projected (2050) environmental pressures on five environmental domains by food group

Source: Springmann et al. (2018)

diseases, including cardiovascular heart disease, cancer and stroke, are increasing in nearly every country, with low- and middle-income countries experiencing rapid rises (Phelps et al. 2024). While many countries are still experiencing double burdens, this increase is largely driven by the rise in obesity. In 2017, malnutrition in different forms caused 11 million deaths and 255 million Disability Adjusted Life Years (Afshin et al. 2019).

While population pressure, environmental degradation, biodiversity loss and climate change directly affect food production and food systems, the way we manage our food systems also affects climate, environment, biodiversity and ecosystem functioning. Addressing these interconnected challenges and creating more sustainable and equitable food systems requires a fundamental transformation to the way food is produced, processed, distributed and consumed (Intergovernmental Panel on Climate Change [IPCC] 2022a; Rosenzweig et al. 2020).

Each environmental pressure is indexed to a score of 100 in 2010. Animal product impacts include feed requirements, and the 2050 projections are based on a business-as-usual socioeconomic development pathway (SSP2). Source: Springmann et al. (2018).

Livestock and aquaculture production contribute to a range of environmental problems, including habitat destruction, deforestation, land-use change, greenhouse gas (GHG) emissions, pollution, marine ecosystem degradation, zoonotic, animal and foodborne diseases and antimicrobial resistance (**Figure 17.2**) (see 8.2.2; 8.3.3) (Zhang 2024; UNEP 2020). The production of animal source food (ASF) accounts for 57 per cent of food production emissions (Xu 2021) and 38.5 per cent of global deforestation (FAO 2022). Around 70-80 billion terrestrial animals and 110 billion fish are raised and slaughtered annually, mostly in intensive systems (Ritchie 2024). ASFs provide an important source of energy and essential nutrients, such as protein, fatty acids, and some vitamins and minerals, especially in areas with low potential for crop production (Beal et al. 2023) and are important for meeting nutritional needs. They therefore provide important component of livelihoods in many subsistence agricultural communities, and hold cultural significance, including to Indigenous communities. However, the scale of the environmental harm associated with ASF production systems means that reducing their impact is essential to achieving sustainability goals (Chapters 10 & 11).

Globalization of food production, distribution, and consumption has resulted in an interconnected and interdependent network of countries and institutions (Greenville et al. 2019; Davis et al. 2021). Between 2005 and 2022, global agricultural trade has nearly tripled in value, rising to $US1.9 trillion (FAO 2022), with emerging market and developing country exports already accounting for more than a third of the global total (FAO 2022). Farmers receive less than 27 per cent of consumer food expenditure (Yi et al. 2021), and food production has become increasingly concentrated. 80-90 per cent of the world's daily calorie and protein needs are currently covered by 12-20 species, and 50 per cent of our diet comes from three crops: wheat, maize and rice (Akinola et al. 2020). In contrast, local and traditional food crops encompass 7000 species, with diverse nutritional and cultural uses (Balinga 2005; Zuza et al. 2024).

Environmental and health outcomes for which there are no markets, i.e., that are economic externalities, including, undernutrition and obesity, GHG emissions, and biodiversity loss, are pervasive in the food system (Faccioli et al. 2022). These unaccounted costs are estimated to be US$15-20 trillion annually, roughly double the US$9 trillion cost of food consumed globally (Hendriks et al. 2023; Ruggeri et al. 2024). These include externality costs comprise $US7 trillion (with a range of 3-11), health-related costs of $US11 trillion (with a range of 3-39), and socio-economic costs of $US1 trillion (with a range of 0.2–1.7) (Hendriks et al. 2023; Ruggeri et al. 2024).

Building on the Sustainable Development Goals (SDGs) and other internationally agreed-upon objectives, **Table 17.1** presents a set of overall goals for environmentally sustainable, socially just, and nutritionally healthy food systems.

If current trends in food production, trade and consumption across the food system continue, outcomes for the environment and society will deteriorate further. Under the modelled reference scenario, which assumes the continuation of current trends (10.3), total food demands and production are projected to increase by 35 per cent globally between 2020 and 2050. This growth is driven by

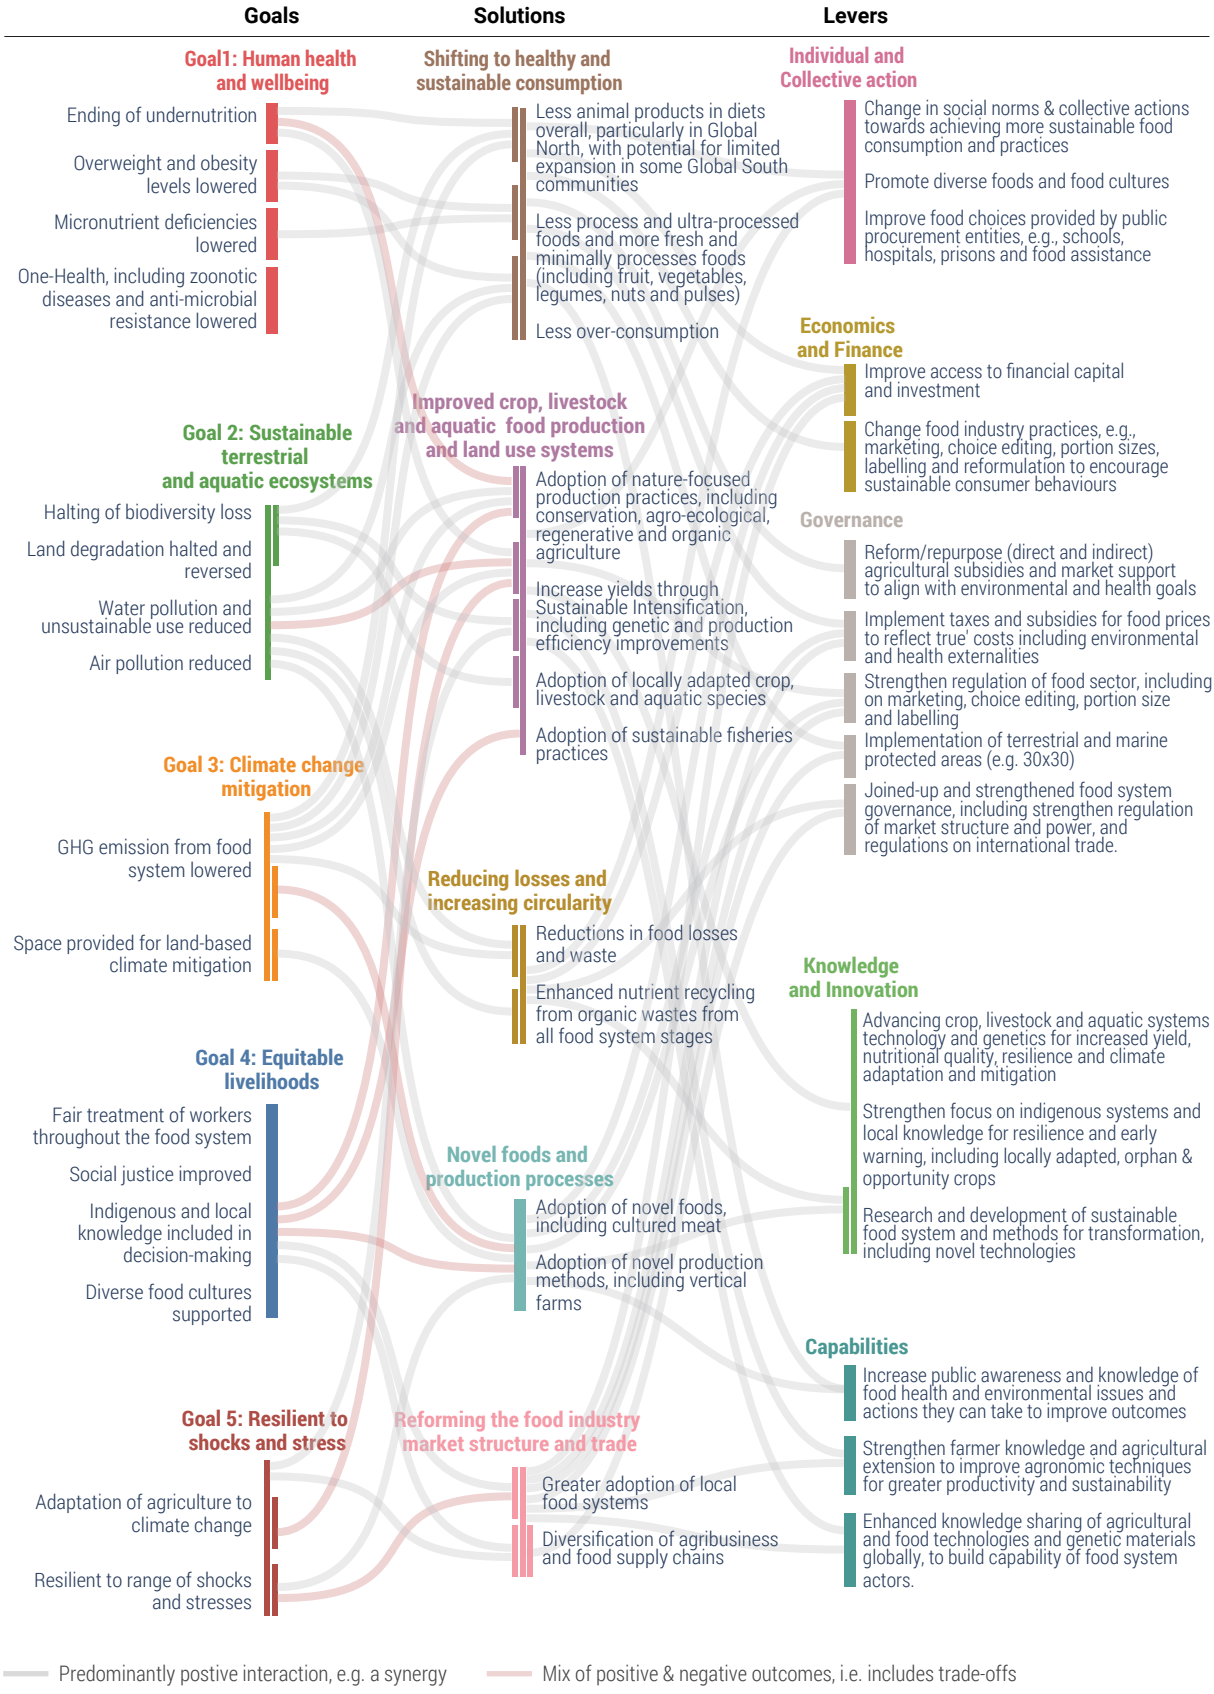
Table 17.1: Overall goals of the food system transformation

Area	Issue	Goal
Sustainable terrestrial and aquatic ecosystems	Biodiversity loss	Halt biodiversity loss and maintain ecosystem functions in terrestrial and marine ecosystems. Close to zero loss of areas of high biodiversity importance by 2030, and the extinction rate and risk of all species are reduced tenfold by 2050 (Convention on Biological Diversity [CBD] 2022).
	Land degradation and soil health	Maintain existing and restore degraded soil health, including by increasing soil organic carbon and microbial diversity, and reduce soil erosion. Achieve land degradation-neutrality by 2030 (SDG target 15.3). Restore 30 per cent of degraded land by 2030 (United Nations Convention on Combatting Desertification [UNCCD] and CBD 2023). Increase soil carbon by 12 per cent by 2050 (FAO 2023).
	Water pollution and unsustainable use	Increase water-use-efficiency by reducing unsustainable water use by 25 per cent by 2050 (Rosegrant et al. 2009), assuming 15-35 per cent of unsustainable water withdrawal can be eliminated by improving water-use-efficiency. Reduce nitrogen pollution from agriculture and food systems by 30 per cent by 2050, assuming an increase in nitrogen use efficiency to above 50 per cent by 2050 in areas where current efficiency remains below 50 per cent (Snapp et al. 2023).
	Air pollution	Reduce food systems related air pollution including $PM_{2.5}$ and ammonia by 30 per cent by 2050 (Montes, Sapkota and Singh 2022; Leon et al. 2022; Ahmed et al. 2024), assuming 30 per cent increase in nitrogen use efficiency and reduction in crop residue burning.
Climate change mitigation	GHG emissions from food system	Achieve a carbon neutral food system by 2040 and become a net-carbon sink by 2050 (FAO 2023). Cut food system methane emissions by 30 per cent by 2030 and halve by 2040, compared to 2020 (Global Methane Pledge 2021; FAO 2023). Halve food systems N2O emissions by 2040 compared to 2020 (FAO 2023; UNEP 2024 and FAO). Achieve food system net climate neutrality by 2050.
	Space for land-based climate mitigation measures, including bioenergy, reforestation, and afforestation	Allow land area for large-scale renewable energy adoption, such as bioenergy and solar energy, as well as other land-based climate mitigation measures, including, reforestation and afforestation, with area requirements defined by associated chapters. No expansion of agricultural land.
Human health and wellbeing	Undernutrition	Provide availability and access to sufficient, healthy, safe, and affordable food for all to end hunger by 2030 and reduce childhood stunting by 40 per cent and halve the 2018 rate of stunting in children of under 5 years by 2030 (Global Nutrition Report 2022).
	Overweigh and obesity	Halt the rise in obesity, diabetes and associated diet-related non-communicable diseases by 2030 (WHO NCD Target 7). This includes a 30 per cent reduction in mean population sodium intake (Target 4) and a 25 per cent relative reduction in the prevalence of raised blood pressure (Target 6), as well as ensuring there is no increase in childhood obesity by 2025.
	Micronutrient deficiencies	End all forms of malnutrition including micronutrient deficiencies by 2030. This includes achieving the World Health Assembly target of a 50 per cent reduction of anaemia among women of reproductive age by 2025.
	One health, including zoonotic diseases and anti-microbial resistance	By 2030, reduce deaths and illnesses from hazardous chemicals and air, water and soil pollution and contamination (SDG 3, Target 3.9). End epidemics of tuberculosis, malaria and neglected tropical diseases and combat hepatitis, water-borne diseases and other communicable diseases (SDG 3, Target 3.3). Promote One Health by balancing human, animal and environmental health, including at least 30-50 per cent reduction of antimicrobial use in the agri-food system by 2030.

population expansion and rising per capita food consumption, including higher consumption rates of animal-sourced foods, particularly in Africa. Consequently, in this scenario global cropland area is projected to expand by 8 per cent, accompanied by more intensive agricultural production practices. For example, nitrogen fertilizer use is projected to increase by 49 per cent, and water abstraction for irrigation by 10 per cent from 2020 to 2050. These changes are projected to boost yields by 28 per cent, but at the cost of further biodiversity loss and GHG emissions. Avoiding the adverse

Table 17.1: Overall goals of the food system transformation (cont.)

Area	Issue	Goal
Equitable livelihood	Fair treatment of workers throughout the food system	Eliminate exploitation and unfair practices in the food industry by 2030. Ensure all farmers and workers receive fair income, safe working conditions, protection of rights and access to social protection measures.
	Social justice	Achieve gender equality in access and ownership of land and other productive resources for agriculture. Ensure gender equality in education, training, capability building and technology transfer. End sociocultural and economic discrimination, including against women and girls, along food system value chain by 2030. Achieve personal security, including, ending gender-based violence, and access to gender responsive workspaces by 2030.
	Inclusion of Indigenous rights and knowledge as well as local knowledge in decision-making	Recognize, integrate and protect Indigenous rights as well as Indigenous Knowledge and Local Knowledge in decision-making processes, policy development, and research. Promote fair sharing and use of genetic resources and diverse knowledge among stakeholders and Indigenous communities.
	Diversity food cultures	Support the significance of food within diverse cultural and religious settings.
Resilience to shocks and stress	Adaptation of the food system to climate change	Adopt climate-smart agricultural practices to adapt to climate change and extreme weather events.
	Resilient to range of shocks and stresses	Build resilient food systems capable of withstanding and recovering from shocks and stresses, while providing sustainable and equitable access to nutritious food.



outcomes and achieving the sustainability goals requires a transformation of the food system.

This transformation must minimize the impact on biodiversity, the environment and the climate while delivering nourishment for all and equitable livelihoods. It requires fundamental changes in the behaviour of all the actors across the food system (Chapter 12), isolated changes or silver-bullet technical innovations will not be sufficient. Key elements of food systems transformation include sustainable intensification of the production system to ensure the long-term productivity, while maintaining environmental functions (Cassman and Grassini 2020); transitioning to more sustainable and healthy diets (Fanzo et al. 2021); minimizing food loss and waste (Galford et al. 2020; Read et al. 2020); and promoting local food systems and circular economy approaches (Hamam et al. 2021). These shifts can be achieved through a combination of appropriate technology and innovation, finance and business opportunity, awareness and education, and collaboration and partnership, all facilitated and incentivised by appropriate policies and regulatory frameworks.

The methodology from Chapter 13 and governance principles from Chapter 12 have been applied to identify the food system goals, the solutions to achieve them, and the underpinning actions required to establish these solutions (**Figure 17.3**). Achieving these goals (**Table 17.1**) requires multiple system changes in the form of multiple solutions (Alexander et al. 2019; Springmann et al. 2018), with each solution involving actions from a range of actors. While solution pathways improve outcomes for one or more desired goals, they may also create trade-offs with unintended or undesirable outcomes, hindering progress towards other goals. Complementary and integrated actions are needed to mitigate trade-offs and leverage synergies to achieve all goals, as is also highlighted in Chapter 11.

The remainder of this chapter outlines five solution pathways for food system transformation to meet the desired goals (17.2). For each solution pathway, a set of actions is identified for actors to take to enable the transformation, along with the associated benefits and trade-offs. Also discussed are the necessary conditions for implementation, including barriers and how they can be overcome. Section 17.3 examines how solutions can be combined to achieve the goals collectively. Section 17.4 discusses cross-system implications and places the solutions within the broader context.

Figure 17.3: Interactions between overall goals, solutions and levers in the food system, showing both synergies and trade-offs

Note: For Goals, Solution Pathways and Levers, the interactions are shown to or from an individual item, e.g., "end undernutrition". Interactions between goals are not shown. Interactions identified as high or medium in strength are shown; therefore, all possible interactions are not depicted. Only intended and positive interactions are shown between actions and solution pathways. The authors identified these interactions based on the chapter synthesis and cited literature; a fuller methodology is provided in Chapter 13.

Figure 17.4: Food System Transformation

Reduce food losses, waste, and increase circularity

Objective: Minimize waste and maximize resource efficiency throughout the food system.

Supply chain improvements: Optimize processes to reduce food spoilage from production to consumption.

Consumer education: Raise awareness of waste reduction practices and the importance of circularity.

Nutrient recycling: Enhance recycling of nutrients and by-products within the food system.

Sustainable packaging: Develop biodegradable and protective packaging to extend food shelf life.

Inclusivity in solutions: Engage diverse actors to ensure that circular approaches are widely adopted.

Develop and integrate novel foods and production processes

Objective: Support alternatives to conventional animal based foods to reduce environmental footprints.

Regulatory adaptation: Adjust regulations to enable safe, widespread use of novel foods.

Research and development: Invest in alternative proteins, such as plant-based, cultivated, and fermentation-derived products.

Sustainable production methods: Use renewable energy and advanced tech to lower the environmental impact of novel food production.

Public-private partnerships: Foster collaboration between governments and businesses to support innovation.

Market acceptance: Work on enhancing taste, texture, and affordability to encourage consumer adoption.

Restructure food industry market and trade

Objective: Create a fair and resilient food system that aligns market practices with environmental and social goals.

Subsidy reform: Redirect agricultural subsidies to promote sustainable practices over harmful ones.

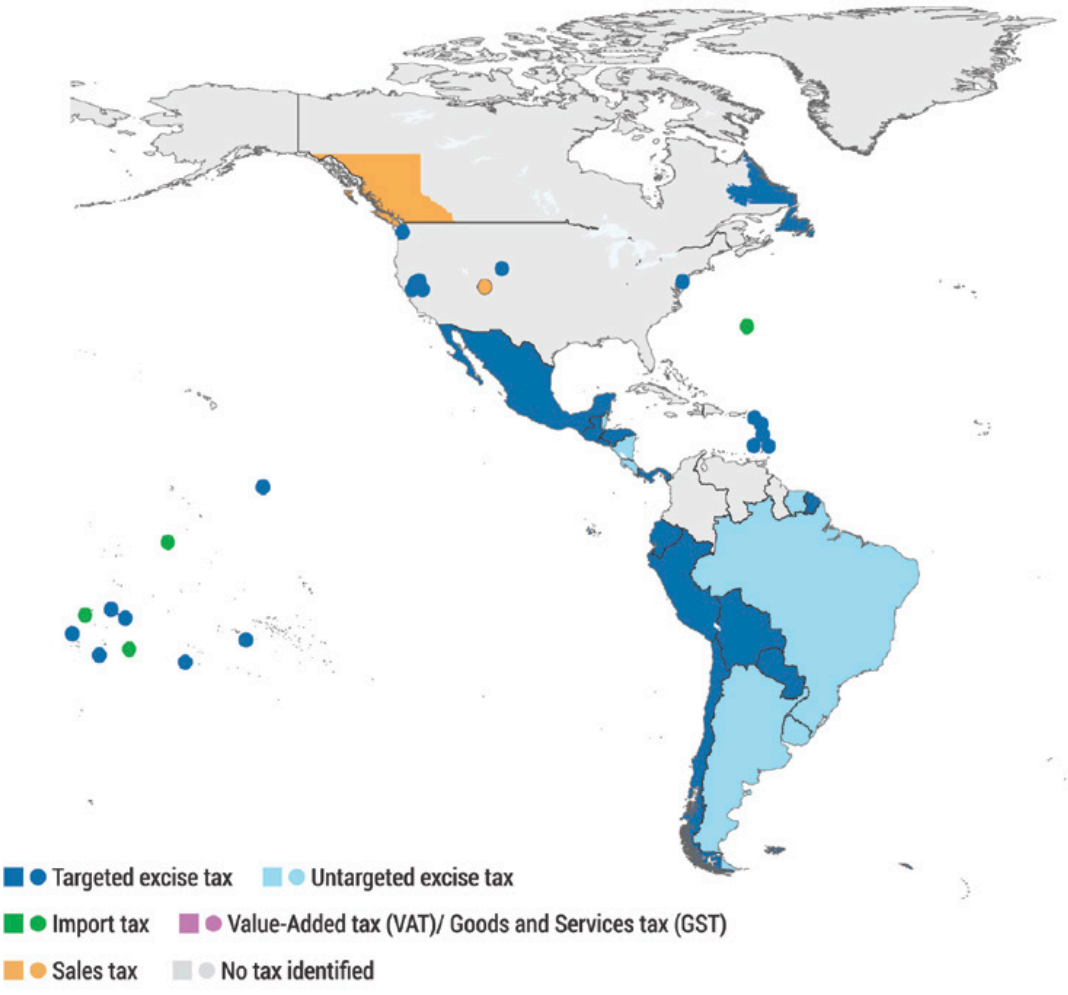
Transparency and accountability: Increase industry accountability for environmental and social impacts through stricter regulations.

Local food systems: Support shorter supply chains and local markets to reduce environmental costs.

Enhanced governance: Strengthen regulatory frameworks to align food industry practices with sustainability targets.

Supply chain diversity: Encourage small-scale producers to participate in the market for more resilient and diverse supply chains.

17.2 Solution pathways for food system transformation



This section describes the five solution pathways (**Figure 17.4**), each accompanied by a set of actions that food system actors can take to advance one or more of the goals. A combination of solution pathways is essential to achieve the required transformation; no solution is sufficient alone to achieve the goals (17.3).

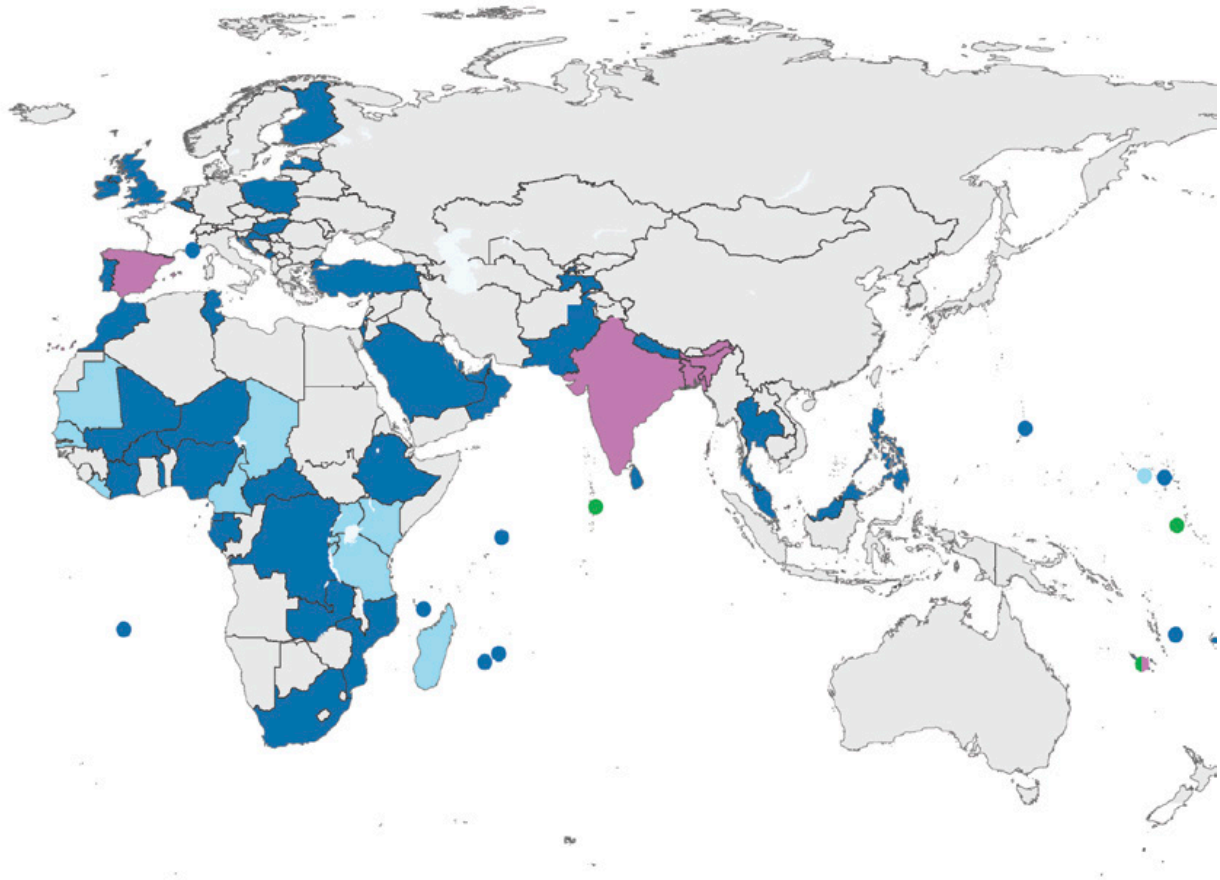
17.2.1 Solution pathway 1: Shifting to environmentally sustainable and healthy diets

Changing diets is a powerful driver for transforming the food system (Vermeulen et al. 2020). Reducing overall consumption of red meat, particularly in high beef-consuming countries, consumption in excess of nutrition requirements and consumption of highly processed foods, as well as reducing food waste at the household and retail levels, can deliver major environmental sustainability and human health benefits (Willett et al. 2019). Reducing food losses and waste and increasing circularity in the food system more broadly is dealt with in Solution Pathway 3 (17.2.3), while this pathway's focus is with consumers' behaviours and diet.

More sustainable consumption is associated with healthier diets (Springmann et al. 2020). Achieving these outcomes requires improving physical, economic and social access to nutritious and minimally processed foods (Schneider et al. 2023), while reducing consumption of unhealthy, highly processed foods (Phelps et al. 2024). The change in diet includes increased intake of whole grains, vegetables, fruits, legumes and pulses, nuts, healthy oils, low-carbon animal-sourced foods and seafood, and, where appropriate and sustainable, novel protein alternatives (Willett et al.2019). Considering food waste as part of consumer behaviours, minimizing food waste at the household and retail levels, is also essential (17.2.3).

Figure 17.5: Current sugar-sweetened beverage (SSB) taxes implemented around the world

While the evidence on the role of dietary changes for improving food systems outcomes is abundant, changing individual food patterns is complex, challenging and requires a range of tools and incentives that respect personal autonomy, culture, social norms, and traditions (Reisch et al. 2017). Nevertheless, various policy innovations and solutions are available to guide, support and encourage healthier and more sustainable dietary choices in all populations (Hawkes et al. 2020).



Influencing behaviours towards healthier and sustainable diet access and choices cut across five lever categories (12.5), as described below.

17.2.1.1 Taxes and subsidies for food prices to reflect true costs, including environmental and health externalities

Consumer food prices that better reflect the true cost of food – including health, environment and social consequences that are unaccounted for in current food prices – would be a strong signal to consumers and be an important step for changing consumption behaviours and advancing food system transformation (Faccioli et al. 2022; Latka et al. 2023; Hendriks et al. 2023). These impacts are typically not accounted for by the market and not reflected in food prices; that is, they are economic externalities (Master and Finaret 2024). If true costs were accounted for, food with high environmental or health burdens, such as red meat, would be more expensive, and food associated with positive health or environmental outcomes, such as legumes, fresh fruit and vegetable, would be less expensive (Funke et al. 2021). Chapter 14 discusses internalizing externalities across the economy (14.3).

While challenging, various methods are being developed to measure, trace, and account for hidden health, environmental, and social costs throughout the food supply chain (Hendricks et al. 2023). Improved accounting

Figure 17.5: Current sugar-sweetened beverage (SSB) taxes implemented around the world (cont.)

can support evidence-based policymaking and help public and private sector actors lower the overall cost of the food system to society.

Government measures could ensure that consumer food prices reflect the true cost of the food (Ruggeri et al. 2024). These policy instruments could include economic measures such as carbon taxes, targeted taxes on high-impact foods like meat, and subsidies for healthier, lower-impact options like fruits and vegetables, or, most likely, a combination of these measures to account for a wide range of externalities.

Many governments have implemented consumer taxes on sugar-sweetened beverages and some ultra-processed foods (Kiesel et al. 2023; Hattersly and Mandeville 2023) (**Figure 17.5**). However, taxation of high-carbon foods, such as ruminant meat, has faced political and social resistance, likely due to vested interests, potentially being regressive, and cultural values.

Reforming or reorienting agricultural subsidies is another government action to better align food prices with environmental and health outcomes (17.2.2). Such reforms, combined with consumer price taxation, could trigger substantive changes to both supply and demand. For example, industrialized nations could redirect subsidies from all forms of industrial-scale animal farming toward plant-based food production (Willett et al. 2019).

However, higher consumer food prices can be regressive, disproportionately affecting poorer populations who spend a greater share of their income on food. Currently, 2.8 billion people cannot afford a healthy diet that meets nutrient requirements and reduces the risk of non-communicable diseases. Such a diet is not affordable for over 75 per cent of the population in sub-Saharan Africa (FAO, IFAD, UNICEF, WHO 2024). Therefore, policies that internalize the externalities of food should be paired with social protection measures to offset potential adverse effects. Funds raised through taxes and saved from subsidy reforms could support those who would otherwise be adversely affected by increasing welfare payments and stronger safety nets, including providing a universal basic income (Beck et al. 2023). The potential impact on those with the lowest incomes should not justify inaction; viable mitigation options for these consequences exist and the urgency for food system transformation is clear.

Changes to a true cost of food pricing would likely substantially affect the livestock industry, due to the associated GHG emissions and biodiversity loss environmental externalities (Ruggeri et al. 2024; FAO 2024). Implementing such a change would require higher net taxation rate for meat and other animal-sourced products (Funke et al. 2021). Some private sector actors oppose such changes as they would increase consumer prices, with the explicit intention of reducing production and consumption of those foods (Sherrington, Carlile and Healy 2023). Greater controls and higher transparency are needed to limit lobbying power to reduce the impacts of vested interests (WHO 2024; 17.2.4.1).

Higher food prices and policies, such as consumer taxation on meat, are seen as publicly unacceptable in many countries (Amaglobeli et al. 2023; Ejelöv et al. 2025). To increase public acceptance and support for true-cost food prices, complementary efforts would be beneficial to shift social norms around food consumption (17.2.1.5), enhance education (17.2.1.4), and reform public procurement (17.2.1.7).

17.2.1.2 Voluntary food industry practices to encourage sustainable consumption

The food industry, including food processors and retailers, holds substantial power to influence consumer behaviours and diet, and can use this to promote sustainable consumption. Industry players influence consumption decisions through various means, such as formulation of foods, advertising and marketing, labelling and choice architecture – small changes to the environments where food choices are made (Bauer et al. 2022). Voluntary changes in industry practices, including marketing and retail food environments, could steer consumer choices towards better environmental and health outcomes. However, a combination of voluntary and regulatory measures is likely needed across various consumer interaction points (Russo et al. 2023).

Marketing and advertising of some food products influence consumer dietary choices and could be used to drive positive change. Examples include advertising in print, television, radio, and social media, engaging with schools such as the sponsoring of events or activities, directing products to children such as including toys or games, and altering product placement in food environments (Smith et al. 2019).

Choice architecture can support the consumption of healthy and sustainable foods (Reisch and Sunstein 2021) by modifying how food is presented and accessed (Lindstrom, Tucker and McVay 2023). This includes placing healthier items at eye level, using them as default on menus, adjusting portion sizes and simplifying preparation and serving (Bucher et al. 2016; Ensaff 2021). The same applies to digital choice architecture, such as the design of food delivery apps (Lohmann et al. 2024). These behavioural interventions, sometimes termed nudging, can be used to influence consumer food choice behaviours and promote positive change (Vecchio and Cavallo 2019).

The food industry has deep expertise in influencing consumer choices, but these efforts are primarily geared to private interests such as maximizing shareholder returns, rather than societal benefits. While voluntary industry actions are possible, it is likely that for sufficiently substantive changes to be made, the incentives for private sector actors need to be aligned to environmental and health outcomes either through policies and regulations (17.2.1.3; 17.2.2.1; 17.2.5) or through commercial benefits arising from a transformation in consumer preferences towards sustainability and health (17.2.1.4; 17.2.1.6).

17.2.1.3 Food sector regulation, including on marketing, choice editing, portion size and labelling

Stronger regulation of the retail food environment and food marketing could be used to align the industry's actions with environmental and public health goals. Rule on how foods can be advertised need to be improved – particularly unhealthy foods marketing directed at children. While information, knowledge, awareness, and guidelines are available across a range of platforms, their reach is overshadowed by pervasive and harmful advertising and cues in the choice architecture by food and beverage companies. The marketing of unhealthy foods has limited controls, particularly on social media platforms (Gerritsen et al. 2021; Kucharczuk et al. 2022; Friedman et al. 2022). Improved regulation in these areas, particularly governing social media and advertising unhealthy foods to young children and teenagers, would be highly beneficial (Hawkes and WHO 2004).

Labelling regulation is another valuable tool for guiding consumer choices. Labelling on the back, and more recently, on the front of food packages is increasingly regulated by state actors and used to alert consumers to unhealthy ingredients or to rate foods on their healthfulness (Shangguan et al. 2019). For example, introducing warning labels about high sugar and salt content in Chile led to a 27 per cent decline in sugar and a 37 per cent decline in salt purchased (Taillie et al. 2021). Regulation and standardization of labelling by governments have incentivized food industry players to reformulate their food products to avoid warning labels or to garner healthier ratings (Fanzo et al. 2023). Another example is the Nutri-Score tool that can inform consumers about healthier choices (Temmerman et al. 2021).

Greater regulation is also required for retailers who sell primarily unhealthy food products. Governments can provide tax incentives for retailers whose sales meet dietary guidelines or change the choice architecture to assist consumers in making healthier and sustainable choices (Rose et al. 2022). Industry resistance and lobbying against the need for greater regulation will likely occur and should be resisted (WHO 2024; 17.2.4.1).

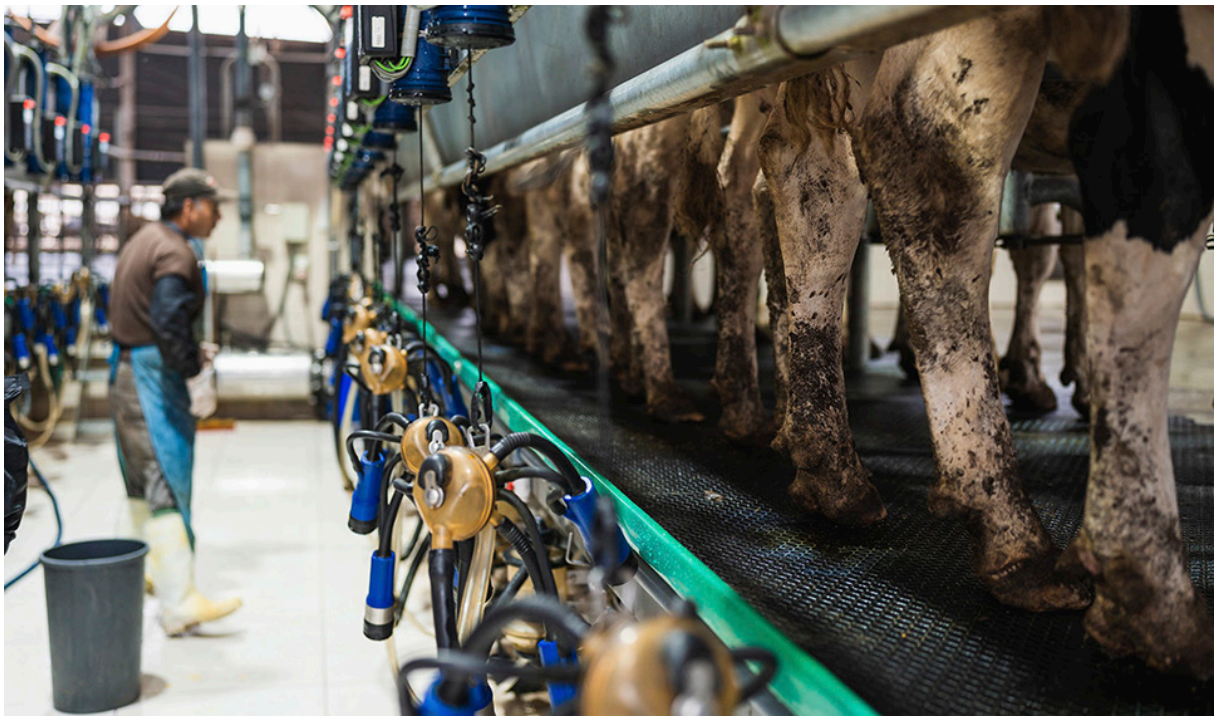
17.2.1.4 Increase public awareness and education on food, health and environmental issues

Providing clear, accessible and trusted information on health and environment aspects of diets helps guide populations towards more informed choices. This information could be delivered in food markets and on labels, front and back of packages, mass media and advertising in public spaces, school cafeterias and curricula, and national food-based dietary guidelines. In low- and middle-income contexts, interventions that prioritize marginalized populations, tailored to their culture, language and relevance to their daily routines, have been shown to improve healthy eating, especially when combined with interventions such as social protection mechanisms (Ruel et al. 2013; Mayen et al. 2016), and when the information is targeted to the group regarding language, food culture, and relevance for their daily lives.

Public awareness and education campaigns can influence consumer attitudes and behaviour. Some examples of such efforts include nutrition education or dietary guidelines (Springmann et al. 2020, James-Martin et al. 2022), having meat-free days (Semba et al. 2024), mass media campaigns such as world hunger day and the National Farmers Day campaign,

food labels (Wolfson et al. 2022, Arrazat et al. 2023), and social marketing (Kenny et al. 2023). However, while these interventions increase awareness (Afshin et al. 2019), they sometimes do not translate into positive long-term sustainable dietary changes (Bailey and Harper 2015), especially when focused solely on individuals, as opposed to changing places and situational contexts where behaviours occur (McGowan et al. 2021).

National food-based dietary guidelines (FBDGs) are science-based, government recommendations and guidelines for healthy eating, aligned with the World Health Organization's guidance on healthy diets. These guidelines serve as a reference for the public, providing recommendations on healthy food, dietary patterns and strategies for a healthy diet (Herforth et al. 2019). FBDGs can also inform or set a standard for public procurement programs, such as school meals, federal food assistance programs, hospitals, and workplaces. As of 2022, 97 countries have FBDGs, but only 27 incorporated environmental sustainability goals and guidance (James-Martin et al. 2022). Aligning FBDGs with environmental sustainability, such as in the EAT-Lancet diet guidance, could increase environmental and health benefits, supporting One-Health goals (Springmann et al. 2020; Bui et al. 2024). However, public compliance with diet guidelines is currently low. To be more effective, the communication of guidelines needs to resonate strongly with consumers. Simplification is often an important step, and guidelines should avoid too technical presentation, but seek messages that are realistic, positive, straightforward, and actionable, without requiring consumers to forego their favourite foods (Webb and Byrd-Bredbenner 2015).



Improving cooking skills and food literacy, for example through cooking classes, increases adoption of healthier and sustainable diets while boosting confidence and positive attitudes (Hasan et al. 2019). However, many people lack access to kitchens, equipment, time, and financial resources (Garcia et al. 2016). Addressing the lack of knowledge and facilities would remove a major barrier to healthy eating (Wolfson et al. 2019) that can encourage people to opt out of more affordable, but less nutritious and sustainable dietary choices, particularly within high-risk vulnerable populations (Hawley et al. 2021).

School gardens can contribute to healthier consumption from an early age (Rico-Sapena et al. 2019, Davis et al. 2015), strengthening links with local biodiversity (Fischer et al. 2019), fostering knowledge about sustainable farming (Ferguson et al. 2019) and preserving biocultural knowledge (Robles-Piñeros et al. 2019). However, integration and maintenance of school gardens in both high and low-income settings often face a lack of funding, inadequate staff and space, low teacher interest and training, and difficulties including activities in the curriculum (Burt et al. 2018).

17.2.1.5 Changes in social norms & collective actions towards achieving more sustainable food consumption and practices

Changing social norms and food cultures could influence the perceptions of the value of food and the acceptability of food waste (Ranganathan et al. 2016; Çoker et al. 2022). Promoting pro-environmental norms and sustainable food consumption behaviours can be supported and sustained by well-targeted media campaigns, including social media (Sarkar et al. 2023). These campaigns could highlight the importance of choosing ethically sourced products, packaged sustainably, and produced with minimal environmental damage, while promoting and normalizing healthy food choices and behaviours among broad audiences (Rini et al. 2024). Partnering with influencers, like chefs and public figures, to endorse and share content on plant-based diets and the importance of choosing sustainably produced and packaged products could further amplify the message and reach a wider audience (Yidirim 2021).

Greater municipal and community engagement, local leadership and grassroots movements can foster connections with local food sources and encourage sustainable practices. These movements can educate about and implement practices like composting and the cultivation of local, seasonal produce through community gardens to larger-scale urban farms. They can also advocate for and support sustainable farming practices at a regional level (Motta 2021). Collective action of consumers and farmers in concert with health and environmental advocates can encourage the food industry to create more sustainable food supply chains, promote local and seasonal produce and reduce food waste (United Nations Environment Programme [UNEP] 2024).

Credit: GSR-PhotoStudio/Envato

17.2.1.6 Promote diverse foods and food cultures.

Integrating a wider variety of foods into people's diets – including locally adapted, Indigenous and underutilized "orphaned" crops – and embracing diverse food cultures, offers multiple benefits for nutrition, environmental sustainability, resilience, and economic opportunities (Talabi et al. 2022; Mabhaudhi et al. 2019; Zuza et al. 2024). Traditional foods contribute to diversified diets and enhance food and nutrition security (Akinola et al. 2020). Actions to support the integration of traditional foods in people's diets are discussed below, while measures to support their production are described in Section 17.2.2.5.

Education initiatives could be explicitly tailored to local food cultures to enhance public understanding and appreciation of benefits, celebrating diverse locally adapted foods. Educational programs can help widen the palate of children and youth, teaching them to appreciate the taste and flavour of new foods and the diversity of diets, including minimally processed and locally adapted foods (Hilimire et al. 2014). Policy interventions that facilitate the inclusion of diverse crops in school meals and public institutions boost their acceptance and normalize their consumption, supported through public procurement guidance or regulation (17.2.1.7).

Greater community engagement would foster local food cultures that supports food diversity. Local governments and community leaders can organize forums, town halls, and food expos to involve residents in sustainable food practices and to celebrate local cuisines. Community-driven projects such as local food co-ops or community-supported agriculture programs strengthen local food systems (Egli et al. 2023), while collaborative events like farmers markets and food festivals connect consumers with local producers, benefiting local economies.

Valuing traditional foods and cuisines through cultural festivals (Kuhnlein 2015), education and tourism (Kalenjuk et al. 2024) can enhance recognition of Indigenous and local food systems and their contributions to sustainability (Lopes et al. 2023). Women, often primary caregivers and food producers, face unique challenges. It is crucial to reduce gender inequalities by recognizing women's unpaid work, closing the gender gap in access to education, financial resources, extension services and technology, and transforming restrictive social norms (FAO 2023 & 2025; Marianne Gadeberg 2023).

17.2.1.7 Design and implement improved public food procurement and distribution

Public procurement in sectors such as schools, hospitals, the military, prisons, and food assistance programs can drive meaningful, albeit incremental, shifts in the food system that accumulate over time

(Parsons and Barling 2021). Public procurement can enhance nutritional quality and promote sustainable eating habits (WHO 2021). Strategically designed procurement policies can stimulate the supply of healthy foods and influence social norms and habits, supporting broader food system transformations (WHO 2021; Swensson et al. 2021; Sidaner, Baladan and Burlandy 2012; Privitera et al. 2024). To improve public procurement, the following key actions are key: set and monitor clear nutritional and environmental criteria that align with national guidelines (i.e., FBDGs), equip procurement professionals with adequate knowledge and training, addressing logistical and ensuring economic feasibility.

Nutrition and environmental sustainability criteria for public food provisioning should be established and monitored, aligning with national FBDGs and ensuring FBDGs incorporate environmental sustainability (Wood et al. 2023). Nutrition and environmental sustainability information for foods and meals needs to be readily available to consumers.

Those involved in designing or working in public procurement food service need sufficient knowledge and training to understand and assess what foods are healthy and sustainable (Guillaumie 2020). Logistical challenges, especially those related to preparing and distributing fresh and perishable healthy foods, must be addressed to facilitate smoother implementation. Solutions include new operating modes such as advanced supply chain software, decentralized food hubs and new recipes. For example, in Brazil and India, engagement with small- and medium-scale processors to supply food to school meal programmes has supported healthier diets, while providing a stable market for local enterprises (Swensson et al. 2020). Brazil's Public Food Procurement program, which supports family farmers faces challenges, including seasonal production gaps, inadequate infrastructure for food storage and processing, and limited technical assistance to farmers (Soares et al. 2024).

17.2.1.8 Synergies, trade-offs, and the need for social protection

While animal-sourced foods are typically more environmentally intensive to produce than plant-based foods, they are also important sources

Credit: seventyfourimages/Envato

of nutrients, including calcium, iron, vitamin B12 and zinc, particularly for people who consume them infrequently. In resource-constrained settings, diets often lack quality and diversity, which includes limited access to animal-sourced foods, increasing risk for nutrient deficiency (Allen et al. 2011; Parikh et al. 2022).

Livestock also contributes to livelihoods and resilience, especially in low-income rural communities. A reduction in animal-sourced food consumption among those vulnerable populations could be detrimental to growth, development, and health. In contrast, in high-income countries, where animal-sourced food consumption is high, shifting towards more plant-based diets could provide health and climate action gains.

Global efforts to reduce consumption of animal-sourced foods must not exacerbate existing injustices and inequities in access to healthy diets. Governments could establish social protection measures, such as welfare and food assistance, to support marginalized and vulnerable individuals and resource-constrained households (Kumar et al. 2021). Incorporating environmental and health externalities into food prices need to be implemented with caution and include protection for vulnerable low-income households (17.2.1.1 and 17.3.4).

Nevertheless, the substantial and essential benefits of these actions are indispensable for achieving the food system goals outlined in **Table 17.1**. Without dietary shifts, there isn't enough land or other resources to produce the necessary food, while protecting biodiversity and meeting climate targets.

17.2.2 Solution pathway 2: Improved crop, livestock and aquatic food production and land use systems

Sustainably increasing productivity is essential for enhancing food security while also freeing up land for ecosystem services and climate change mitigation (IPCC 2019; Tittonell and Giller 2013; Godfray and Garnett 2014; Keating et al. 2014; Pradhan et al. 2015). However, intensifying crop, livestock and aquatic systems without modifying current production models can further harm the environment and ecosystem (Raj et al. 2022; Clay et al. 2020). Expanding agricultural land to produce more food has substantial climate implications, biodiversity loss and environmental degradation (Maeda et al. 2021). In contrast, restoring degraded land and bringing it into agricultural production may improve production and carbon sequestration (Jat et al. 2019; Sapkota et al. 2019).

Sustainable intensification combines genetic improvement in crop, livestock and aquaculture with a range of locally adapted sustainable production practices to increase food production while minimizing environmental harm (Garnett et al. 2013; Eyhorn et al. 2019). Sustainable transformation of terrestrial and aquatic food production requires a balance between sustainable intensification and nature-based practices (Chapter 18). This means that productivity gains need to be aligned with the preservation of ecosystem services, social responsibility, animal welfare, and resilience to shocks (Vanlauwe et al. 2014).

Development and promotion of high-yielding crop varieties and breeds of livestock and aquatic species have historically increased yields and helped reduce hunger (Ricciardi et al. 2018) and continue to drive productivity gains (Avana-Tientcheu and Tiambo 2020). Genetic improvements could be further enhanced through integrated breeding strategies, combining conventional, marker-assisted, and genomic breeding and unlocking favourable genetic variations, locally adapted traits, precise envirotyping, to heighten selection intensity and to shorten selection cycle (Xu et al. 2017). Breeding for biotic and abiotic stress tolerance, better root systems, higher feed conversion ratio, and improved nutrient-use efficiency can substantially increase production, while increasing resilience against shocks and reducing GHG emissions. However, these genetic breakthroughs should be combined with a range of transformative management practices, such as agroecological approaches, resource-efficient technologies, soil health restoration, and climate-resilient farming systems to ensure long-term productivity, environmental sustainability, and food security.

Various management practices have been developed, tested, and validated to enhance the sustainable production of crops, livestock, and aquaculture systems, contributing to food security and environmental goals. Some examples include conservation tillage and crop establishment (Aryal et al. 2015; Jat et al. 2020; Sapkota et al. 2022), diversified crop rotation

Credit: Sebastian_Studio/Envato

and cropping system management (Ladha et al. 2016), precision nutrient and water management (Jat et al. 2015; Sapkota et al. 2021; Snapp et al. 2023), and improved livestock feeding strategies, including grazing rotation, animal welfare enhancements, and manure management (Herrero et al. 2016).

In India, implementing just three sustainable intensification technologies - efficient fertilizer use, conservation agriculture and rice water management - could reduce agricultural emissions by approximately 10 per cent, without compromising production (Sapkota et al. 2019). Although increasing food production through intensification may result in greater absolute GHG emissions, maintaining the same level of yield through precision nutrient and water management could contribute to long-term food and nutrition security and climate change mitigation, while also improving soil health.

A holistic approach is needed in livestock production systems, combining improved husbandry practices, strengthened biosecurity, alternative health interventions like vaccination and probiotics, responsible antibiotic stewardship, sustainable waste management, and policy-driven incentives.

Implementing recirculation systems and enhanced feed management practices in aquaculture improves water, nutrient, and energy use efficiency (Verdegem et al. 2022). Mariculture can use ocean space to build aquaculture farms (Schubel and Thompson 2019), reducing competition for land. Climate-adaptive fisheries reforms minimize negative impacts on wild-caught fisheries and increase their resilience to the effects of climate change (Beckensteiner et al. 2023).

Regenerative and agroecological practices, such as conservation tillage, crop residue recycling, production system diversification (Snapp et al. 2021), cover cropping, agroforestry (Niether et al. 2020), and mix crop-livestock (Bezner Kerr et al. 2021), as well as crop-livestock-fish (Keating et al. 2014) farming system, enhance biodiversity (Pettorelli et al. 2021; Dunlop et al. 2024), nutrient cycling (Giller et al. 2021), productivity and farmers' income. The practices also contribute to climate change adaptation and mitigation efforts by enhancing and functioning the root systems, increasing soil organic matter (van Groenigen et al. 2017) and reducing fossil fuel dependence (Aguilera et al. 2020).

Sustainable soil and water management are essential for sustainable food production, ensuring

efficient resource use, enhanced ecosystem services, and climate resilience. Integrated approaches, including precision water technologies from farm to watershed scale (Sikka, Alam, and Mandave 2022; Cofie and Amede 2015), renewable energy for irrigation (Fraunhofer ISE 2024), and soil-health enhancing practices, like residue recycling, optimize nutrient cycling, water retention, and carbon storage, supporting long-term agricultural sustainability (Jat et al. 2015; Kumar et al. 2023; Hiranmai et al. 2023).

Achieving long-term food security and environmental sustainability through the use of beneficial technologies for production of crop, livestock, and aquatic species requires a coordinated set of actions. These include advancing technology and genetics (17.2.2.1), leveraging Indigenous Knowledge (17.2.2), reforming agricultural subsidies (17.2.2.4), implementing protected areas (17.2.2.7), changing food industry practices (17.2.2.5), improving financial access (17.2.2.2), and enhancing farmer education and extension services (17.2.2.3).

17.2.2.1 Drive advanced research and innovation in crop, livestock and aquatic production systems

Cutting-edge research and innovation in genetic improvements and production systems management tailored to specific production circumstances are needed. This requires fundamental and applied research to unlock the genetic potential of crop, livestock, and aquaculture to develop varieties and breeds with improved biotic and abiotic stress resistance, including adverse environmental conditions, improved resource-use efficiency, increased productivity and enhanced nutritional quality (Jamir et al. 2024; Rojas-Downing et al. 2017; Lu and Luo 2020; Gratacap et al. 2019; UNEP and FAO 2024). Some aquatic species possess high fecundity and external fertilization (Gratacap et al. 2019) that can facilitate genome editing to produce favourable production traits, such as disease resistance.

Genetic breakthroughs should consider traditional and Indigenous Knowledge systems and leverage precision technologies to optimize resource use, monitor crop, livestock and aquatic species health, enhance overall productivity, and promote sustainability and resilience. Collaboration between national and international research institutions, universities and advanced research institutes, and the private sector can develop and validate advanced breeding techniques, build robust phenotyping platforms and high-throughput screening capabilities (Araus and Cairns 2014), providing training, advisory services and establishing effective distribution channels (Mangeni 2020).

Genetic innovations should be combined with sustainable production practices, such as precision agriculture or aquaculture, diversified cropping or species production, conservation agriculture or restorative aquaculture, or crop-livestock-aquaculture integration, to optimize nutrient cycling, enhance soil health, biodiversity and overall productivity.

National Agriculture Research and Extension Systems, universities and international research organizations should invest in sensors, satellite, big data analytics and artificial intelligence to understand soil, environment and climatic conditions. Integrating these data streams with farm management and decision support systems will generate site-specific management recommendations (Snapp et al. 2023). Application of advanced knowledge on symbiotic nitrogen-fixing mechanisms and nutrient cycling is needed to develop and grow self-fertilizing cereal crops (Guo et al. 2023), including those regulating nutrient cycling processes through nitrification inhibition (Leon et al. 2022). Another emerging research area is developing an integrated multi-trophic aquaculture system that combine finfish culture with lower-trophic-level species, such as seaweeds or bivalves, to recycle nutrients and allow for maximizing resource utilization, while minimizing environmental impacts (Ren et al. 2010; Edwards 2015).

Understanding the ability of agroecology and other innovative approaches to address climate risks, enhance the resilience of farming systems, and improve the flow of resources from diverse ecosystem services (Sinclair et al. 2019) is also critical. Disseminating such knowledge available to all value-chain actors, such as farmers, input and output dealers, policymakers and public (Kaufmann et al. 2023) is often lacking. This is particularly important in low-income countries as they often lack adequate knowledge from a system perspective (Mockshell and Villarino 2019).

Sustainable fisheries can be supported through small-scale, low-impact fishing methods that

Credit: Cookelma/Envato

use socially innovative, locally adapted practices (Akinsete et al. 2022). Improving fisheries governance through innovative community-based schemes can help develop new distribution systems, support local communities through employment, initiate new networks, and facilitate collaborative actions across fishers. Adequate monitoring, data analysis, and improving processes at all levels can drive transformation in fisheries management (Moe Føre et al. 2024).

Moreover, research efforts can also focus on designing future crops, animals and production systems to develop resilient, resource-efficient and climate-adapted crop varieties and livestock and fish breeds, together with innovative production systems such as urban agriculture, vertical farming (Oh and Lu 2023) or integrated aquaculture-agriculture models (Sekaran et al. 2021) to intensify production sustainably. Several sustainable fisheries management measures, approaches, and practices exist to minimize negative impacts from wild-caught fisheries operations and increase their resilience to climate change impacts, such as through climate-adaptive fisheries reforms that incorporate ecological and industry management responses (Beckensteiner et al. 2023).

Beyond sustainable intensification at the farm and landscape levels, food system transformation requires research and innovation on governance, power dynamics, political economy, inclusiveness, market instruments and finance. Scientific and professional bodies such as CGIAR (Govaerts et al. 2021), Global Alliance for Climate-Smart Agriculture, Sustainable Agriculture Initiative Platform, Global Forum on Agricultural Research and Innovation, Africa Food System Forum, National Agricultural Research and Extension Systems, farmers' group and civil society organizations play a crucial role in this transition by supporting research, providing educational resources, and building capacity for scientists, educators, managers, and businesses. These organizations should also help develop, harmonize, and standardize protocols and metrics for monitoring the effectiveness of transformational technologies for food security and environmental safeguards. National governments are responsible for creating enabling institutional mechanisms and

policy environments that catalyze greater international cooperation, knowledge sharing and scaled implementation of sustainable farming practices.

Private sector players can drive advancements in environmental sustainability by investing in cutting-edge research and technology development, such as genetic innovation, precision agriculture, water-efficient irrigation systems, renewable energy, greener cattle initiatives for enteric methane reduction, environmentally sound fertilizers, such as green ammonia, among others. Through public-private partnerships, businesses can accelerate the development and implementation of sustainable practices, such as organic fertilizers, biopesticides, and sustainable feed options, while advancing clean energy integration to reduce the reliance on harmful chemicals and fossil fuels, reducing the carbon footprint and improving soil health and biodiversity.

17.2.2.2 Improve access to financial capital and investment

Government and international organizations could commit to long-term efforts to design, develop, test and deploy agricultural and aquaculture technologies and approaches, allocating funding and resources to support such research and development. Strategies and policies that increase investments in sustainable production practices and nature-based solutions, including those that enhance soil health and ecosystem services, are crucial for the long-term sustainability and profitability of food production systems. More funding can be mobilized by linking transformative approaches with Sustainable Development Goals and leveraging financial support through international institutions, like the World Bank, multi-national development banks, and global financial institutions (Mukherji et al. 2023). High interest rates, currency instability, and inflation in developing countries often make finance costly and inaccessible for farmers and innovators. Targeted solutions such as subsidies, credit guarantees, stable monetary policies, and concessional lending from international institutions can help lower financial barriers and improve access to sustainable investment.

Leveraging a suite of financial mechanisms, stakeholders across the public, private, and philanthropic sectors can help overcome barriers and accelerate the transition towards more resilient and equitable food production systems.

Public-private partnerships can unlock investments in sustainable production systems through blended finance models, combining public, private and philanthropic capital. Payment for ecosystem services and well-designed carbon credit schemes can compensate farmers and landowners for providing environmental services, like carbon sequestration and biodiversity conservation, creating new revenue streams (Pagiola et al. 2020; Wunder et al. 2020; Wongpiyabovorn et al. 2023).

The private sector can support a sustainable food system by adopting responsible sourcing (Kamgang et al. 2023), ensuring fair compensation to producers, and optimizing supply chains, including investing in cold storage and efficient logistics to reduce food losses. Agricultural input companies should invest in precision farming technologies, including GPS-guided equipment and data analytics, to improve resource-use efficiency.

Private sector groups can also develop and provide sustainable feed options for livestock and aquaculture that eventually help reduce the environmental impact of livestock and fish farming, promoting healthier production systems. For example, Cargill and InnovaFeed are developing insect-based protein feed (Cargill 2024). Similarly, start-ups can provide renewable energy solutions for farm machinery, water pumping and irrigation systems, nutrient management, drying agricultural products, and heating and cooling solutions (Gorjian et al. 2022). Platforms like the World Intellectual Property Organization can facilitate access to finance and capital investment by connecting technology providers, seekers, and investors.

While private investment is crucial for advancing sustainable food systems, it raises concerns about ownership of knowledge, data, and intellectual property, potentially restricting access for smaller producers and public institutions. Additionally, conflicts of interest may arise if mixed investment portfolios prioritize short-term financial gains over long-term sustainability, undermining public oversight and resource allocation.

Developing innovative financial instruments, such as sustainability-linked loans or green bonds, can attract private capital (Flammer 2021). National and international organizations can deploy de-risking mechanisms, such as loan guarantees and risk-sharing facilities, to mitigate investment risk and incentivize private-sector funding in projects with environmental or social benefits. Similarly, microfinance institutions and agricultural development programs could offer farmer-tailored financial products, including affordable credit, savings, and insurance schemes, to enable smallholder investments in sustainable farming, building their economic resilience (Meyer 2014).

17.2.2.3 Enhance knowledge sharing for food producers through education and knowledge extension programs

Increased knowledge sharing and capacity building of farmers, extension agents, and other food value chain actors strengthen institutional capacity and improve knowledge, skills, and confidence for widespread adoption of sustainable production practices. This, in turn, enhances food security, producer livelihoods, and long-term environmental and economic resilience of the agricultural, aquaculture, and fisheries (Humphries 2018; Akpoviri et al. 2023; Kommey 2023). Effective capacity building can be supported by establishing comprehensive data and knowledge sharing platforms that harness the capabilities of big data analytics, machine learning and artificial intelligence (Delgado et al. 2019; Jimenez et al. 2019). Farmer-to-farmer learning networks and information and communication technologies for knowledge sharing can increase the speed of dissemination and accelerate the spread of best practices, empowering farmers with efficiency and productivity (Capponi 2023; Pandey 2021). For example, various CGIAR centres have established data platforms that collect data from satellite imagery, farm surveys, climate models and provide producers with real-time weather updates and agroadvisories, helping farmers select appropriate crops and management practices to enhance crop yields, improving soil health and managing climate risks. Education and knowledge dissemination facilitate interaction among farmers and various stakeholders, fostering behaviour change and better utilization of funds and competencies (Nyaplue-Daywhea et al. 2021; Kirkwood et al. 2022; Kabir and Islam 2023).

Government extension systems need to incorporate digital advisories and pluralistic extension models, involving non-government organizations, private agribusinesses and farmers' organizations to provide technical assistance, agroadvisories and market access. To be effective, these systems require adequate financing and effective channelling to extension services (Food and Land Coalition 2019). Local institutional capacities of grassroots-level organizations can be strengthened through collaboration with universities, advanced research institutes and vocational training centres.

Farmer education initiatives should aim to promote gender equality and inclusion by prioritizing the adoption of inclusive agricultural tools and technologies, such as lightweight farming tools, mobile-based agricultural advisory services, and solar-powered irrigation systems, and mainstreaming Indigenous Knowledge as well as local knowledge (Sitachew, Jeyabalasing and Debela 2018). Promoting gender and social inclusion along the supply chain is also essential (Frangoudes and Gerrard 2019).

Achieving inclusive and equitable outcomes requires cross-sector collaboration among public education and research committees, finance and development agencies, farmer network representatives, community leaders, civil society organizations, and local authorities. Technical schools and universities can also participate by incorporating non-environmental or non-agronomic disciplines, such as law, engineering, architecture, economics, or business. Together, these stakeholders can develop gender-responsive funding and appropriate financial support for farmers, design curricula for farmer education and extension services to support the uptake of sustainable farming and harvesting practices (Davis 2022; Vafadarnikjoo et al. 2023; Vieira et al. 2023).

17.2.2.4 Reform/repurpose agricultural subsidies

Subsidies are policy tools to provide financial incentives that encourage environmentally sound practices among producers. Subsidies can take various forms, such as direct payments for ecosystem services, minimum price support, price premiums for sustainably produced food, and technical assistance for adopting sustainable farming techniques.

These can promote producing and marketing more environmentally sound, humane and sustainable products or systems.

In most OECD countries, most subsidies are directed towards intensively grown commodities, such as rice, sugar and a range of livestock products, which account for about 80 per cent of GHG emissions from agriculture (Mamun et al. 2019), disproportionately favouring large corporations over small and medium-sized enterprises, which benefit local communities and food systems. This approach tends to promote monoculture and input-intensive production systems, discouraging the production of more nutritious foods, such as vegetables, fruits, legumes, eggs, and fish that follow integrated production systems (Mamun et al. 2019).

Reforming agricultural subsidies is essential to drive the transition toward sustainable and resilient food systems. This involves phasing out support for environmentally harmful practices and redirecting financial incentives toward sustainable inputs, agroecological methods, and innovative technologies that enhance both productivity and ecological integrity (Piñeiro et al. 2020). Governments can reinforce these incentives with penalties for unsustainable practices (Nordhaus 2017), creating a balanced system of rewards and deterrents. A comprehensive review of existing subsidy programs is needed to identify and correct biases that prioritize input-intensive, yield-maximization approaches at the cost of environmental and public health. Effective reform requires inclusive engagement with policymakers, farmer organizations, and stakeholders to ensure that subsidy policies align with broader goals such as food security, climate resilience, biodiversity conservation, and human well-being.

One prominent example is revising fertilizer subsidy policies in India to phase out subsidies on urea and increase support for phosphorus and potassium fertilizers. This can promote balanced fertilization, leading to increased yield, reduced cost of production, and reduced environmental pollution (Sapkota et al. 2021). Other examples of repurposing subsidies include shifting to output-based payments, providing transition support for farmers moving to agroecological methods, and integrating subsidies with other financial incentives, such as payment for ecosystem services and price premiums for sustainable products. In fisheries, subsidies can also be repurposed to encourage sustainable aquaculture practices, such as integrated multi-trophic aquaculture (Knowler et al. 2020) or modernize the aquaculture sector for improved yields and environmental outcomes (Guillen et al. 2019).

However, reforming agricultural subsidies may face strong resistance from policymakers, agribusinesses, and industry lobbies that benefit from existing production-focused incentives. Policymakers often fear political backlash from farmers and rural communities reliant on existing subsidies. Therefore, the transition must be phased and inclusive, requiring financial restructuring, strong political will, and stakeholder consensus to maintain food security and stability of rural economies throughout the process.

17.2.2.5 Change food industry practices to encourage sustainable production

The food industries play a pivotal role in food system transformation, with the potential to either exacerbate negative consequences (Slater et al. 2024) or drive positive change (Prasanna et al. 2024). While the influence of food industry practice on consumer behaviours and diet is discussed in Section 17.2.1.2, this section focuses on how food industry action can generate positive systemic change by creating powerful incentives and market signals that drive the widespread adoption of sustainable production practices. For example, companies can commit to sourcing raw materials from suppliers who adhere to sustainable practices, requiring suppliers to meet sustainability benchmarks. At the same time, third-party certification and traceability systems (e.g. blockchain) can improve transparency and consumer trust.

Mandatory sustainability labelling and certification schemes can boost consumer awareness and demand for nature-focused products. Government-supported market linkage and procurement programs should prioritize sustainable food products, while providing marketing and branding support to private enterprises to promote their environmentally responsible products and services.

Consumers play vital role to a sustainable and resilient food system by making informed choices and prioritizing traceable, locally produced food. Strengthening connections between local producers

Credit: DC_Studio/Envato

and urban markets, along with widespread adoption of eco-labels and carbon labelling, can enhance transparency and shift preferences toward sustainably produced goods (Miranda-Ackerman and Azzaro-Pantel 2017). These consumer-focused strategies are most impactful when embedded in evidence-informed, holistic food system governance (Costello et al. 2020; Melnychuk et al. 2021; Boyd et al. 2020; Delabre et al. 2021; Farmery et al. 2022).

Indigenous and traditional crops – well-adapted to degraded soils, harsh climates, and a range of biotic and abiotic stresses – are vital for enhancing local climate resilience and restoring fragile landscapes (Tadele 2019), yet they remain marginalized in policy, with limited research investment, poor market access, and underdeveloped value chains (McMullin et al. 2021). Strengthening these diverse, locally adapted crops, livestock, and aquatic species can boost biodiversity, food security, and climate resilience (Chivenge et al. 2015; Akinola et al. 2020). To unlock the potential of Indigenous crops, targeted policies, increased research investment, and stronger market integration are crucial.

Preserving traditional agricultural knowledge, including the use of medicinal plants, community shrines, and living libraries, sustains biodiversity and supports diversified, nutritious diets (Moghaddam et al. 2017; Aniah and Yelfaanibe 2016; Sraku-Lartey 2021; Kruger et al. 2018; Mensah et al. 2021). This requires improving seed availability, integrating Indigenous Knowledge and Local Knowledge holders and their insights into public service, and treating conservation and cultural preservation of Indigenous Knowledge and Local Knowledge as a priority. Research and policy should enhance community seed banks and promote farmer-managed seed systems (Zuza et al. 2024).

17.2.2.6 Implement terrestrial and marine protected areas

Effectively implementing and managing terrestrial and marine protected areas promotes environmental sustainability through preserving biodiversity, protecting critical ecosystems, and mitigating climate change impacts. For more details, see chapter 18.3.1 on environmental system transformation pathways.

17.2.3 Solution pathway 3: Reducing loss and waste and increasing circularity

This solution pathway focuses on reducing food loss and waste along the food system and enhancing circularity, where losses cannot be eliminated. Food system losses, including food waste, occur at all stages of the food

system and account for 30-40 per cent of agricultural production, representing more than US$1 trillion worth of food, with losses contributing to food insecurity and environmental degradation (UNEP 2024; Surdulescui et al. 2023; de Sousa et al. 2024; Alexander et al. 2017a). Food waste is a loss that occurs at the retail, food service or household level (Gustavsson, Cederberg and Sonesson 2011), and accounts for 19 per cent of available food (UNEP 2024). Additional losses occur earlier in the supply chain from post-harvest handling through to processing and distribution. Consumption exceeding nutrient requirements can also be considered a loss (Alexander et al. 2017b; Franco et al. 2022).

Food system waste and by-product streams, including human waste, are often not handled in a circular manner. Currently, over 80 per cent of wastewater, 95 per cent in low- and middle-income countries, is discharged without treatment or to capture nutrients, leading to environmental damage and lost opportunities for nutrient recovery (UN Water 2017). Reducing food losses at source, including, reductions in consumer waste, overconsumption, spoilage, transport and on-farm losses, along with increasing circularity at every stage of the food system would reduce environmental harms and improve food availability (Manzoor et al. 2024; Ellen MacArthur Foundation 2021; Franco et al. 2022) (15.4).

Losses can be reduced by better understanding what and where losses occur, limiting damages during processing and handling, increasing shelf-life through packaging and developing new foods that reduce losses. Behaviour changes to prevent food loss and waste can be initiated by ensuring a positive attitude and better food choices among consumers and using food-saving technologies (UNEP 2024). Actions to improve circularity include recovering on-farm nutrients, including through composting and anaerobic digestion, empowering producers with knowledge and skills on circularity, leveraging technology to convert waste or by-product streams into higher value products, promoting nature-based circular approaches, and ensuring inclusivity and collaboration. As with other solution pathways, progress depends on research and development (17.2.4.1), and targeted investments (17.2.2.2).

17.2.3.1 Value chain actions to reduces loss and waste

Improved measurement of food loss and waste rates through the value chain would help to prioritize actions and employ sustainable operations to prevent the losses (Dora 2021). Identifying and addressing inappropriate systems and poor storage and packing during processing and handling can reduce food damage (Karanth et al. 2023). Extending shelf-life through digital, practical, user-friendly tools is an effective strategy to reduce food waste (Reyes, Cahill and Solval 2024). Packaging plays a key role in extending shelf-life and protects products from contamination or mechanical damage, contributing to reduced food losses during transportation, retail and in households. However, evaluating environmental impact of packaging is essential to identify and manage trade-offs (Paiva and Ugaya 2024). For example, fruits and vegetables should be sold loose unless it can be shown that plastic packaging reduces overall food waste. Biodegradable packaging materials (e.g. derived from onion solid waste) can serve as indicators of bioactive components, displaying the freshness in real-time (Thivya et al. 2023). Natural, edible and nature-based preservative material, such as chitosan, have been shown to increase shelf-life, maintain quality and reduce food losses of perishable foods (Chaudhary2024). Spoilage losses can be reduced by improving storage facilities, including maintaining and monitoring for appropriate moisture levels and controlling pests (Bradford et al. 2018). Solar-powered cold storage units in regions with limited infrastructure can enhance food preservation (Amjad et al. 2023). Smart systems that optimise storage conditions based on real-time data can also extend the shelf life of perishable products (Mustafa et al. 2024).

17.2.3.2 Leverage consumer attitude toward circularity

Positive attitudes among consumers to prevent food waste can reduce losses and promote circularity (Prestes Floriano 2024; Veselá, Králiková and Kubíčková 2023). Measurement of food waste can trigger behavioural change encouraging better planning in cooking and purchasing (Ramos et al. 2024), while food-saving applications can promote ecologically conscious behaviors (Balińska, Werenowska, and Jaska 2024). An example is the TooGoodToGo app which increased acceptance of buying leftover food in many countries. Surplus food re-distribution through charitable initiatives can help reduce food loss and waste (Kenny and Sage 2021), while increased transparency and consumer knowledge on date labels, such as the difference of “best-before”

versus "use-by" dates, can cut food waste (World Resources Institute 2022).

Another method for reducing food losses include novel practices for setting smart distribution, use of machine learning algorithms, which can help to classify, identify and predict contamination levels of leftover cooked food (Matera and Genovese 2024; Azman, Azir and Khairuddin 2024). Innovative applications for sorting and weighting "pay-as-you-throw" food waste schemes, or other financial or taxation-based incentives, can help reduce household and canteen food waste, as shown in the Republic of Korea (Kim and Lee 2020; Broad Leib et al. 2023). Higher food prices (17.2.1.1) may also influence to adopt consumer waste-reducing behavior (Veselá, Králiková and Kubíčková 2023).

Eating more of the edible parts of plants and animals, like offal and commonly discarded vegetable leaves and stems, makes the food system more efficient and circular (Font 2023). Widespread adoption of such changes may require intervention to encourage changes to social norms (17.2.1.5-7) (Llauger et al. 2021). Enhancing the direct connections between producers and consumers, for example with agroecological systems, urban and peri-urban agricultural and school food gardens, can also strengthen circularity and reduce losses (Voge et al. 2023).

17.2.3.3 Increasing circularity and nutrient recycling across the food system

The production of some waste and by-product streams is inevitably associated with the food system. Circular approaches can make fuller use of these resource streams, including greater recycling of on-farm and food industry by-products and wastes, and nutrient recycling from human wastewater. When poorly managed, the decomposition of organic materials generates methane, a potent greenhouse gas (Karakurt et al. 2021).

Farm-level by-products can be used converting agricultural residues into biofuels or biomaterials, reducing reliance on non-renewable resources and lowering environmental harms (Kumar, Sasikumar and Dhilipkumar 2024; Ginni et al. 2021; Riseh et al. 2024). Composting and anaerobic digestion of food system waste and by-products, including municipal food waste, can help close nutrient loops and reduce GHG emissions (Le Pera et al. 2022; Yaser et al. 2022; Murphy and Power 2006). Insects can recycle nutrients from food waste or by-products into feed suitable for livestock and aquaculture (Ojha, Bußler, Schlüter 2020; Lalander Nordberg and Vinnerås 2018).

Nutrients – such as nitrogen, phosphorus, and potassium – should be recovered from human wastewater, turning waste disposal challenges into resource recovery opportunities (Sniatala et al. 2023; Browlie et al. 2024). Capturing and recycling nutrients from human waste reduces the need for chemical fertilizers, a major user of natural gas and GHG emitter, that drives demand for mining of phosphorus and potassium ores (Macura et al. 2021; Day, Alexander and Maslin 2023; Browlie et al. 2024). However, potential risks for soil contamination with pharmaceuticals, heavy metals or persistent organic pollutants must be carefully addressed through appropriate measures, treatment and regulation (Buta et al. 2021; van der Broek et al. 2024).

Nature-based approaches, including Indigenous food production systems, should be promoted, as these typically minimize waste by using each product and by-product. For example, animal products are used for food, clothing, housing, and other materials. Integrated systems, such as combining fish farming with aquaponics vegetable production, reusing waste from the fish to nourish the plants. These systems improve resource efficiency and productivity (Limbu et al. 2017).

17.2.3.4 Engage actors and ensure inclusivity and networking

Inclusivity and collaboration across the food system would help to increase circularity and reduce losses (Somlai 2022), transitioning toward a Circular Society (e.g., Jaeger-Erben et al. 2021; Frojan et al. 2023). Small-scale farmers remain under-represented in food system governance (Avikal et al. 2023). Involving them, including updating infrastructure and farming equipment, supports circularity. Effective waste management policies, technologies, and targeted incentives are key enablers (Sahoo et al. 2023; Shukla, Pullabhotla and Baylis 2023; Gitau et al. 2024). Collaboration between governments, the private sector, educational institutions, researchers, and consumers can provide insight on new co-products and better handling of waste

(Bechir et al. 2023) (14.4 & 15.2.3), while supporting suitable business models and financing (17.2.2.2). Additionally, such collaborations can encourage industries to use more recycled materials and waste streams (Shafqat et al. 2023).

17.2.4 Solution pathway 4: Novel foods and production processes

Novel foods, including alternative proteins, such as cultivated meat (i.e. cellular agriculture), novel plant-based foods and fermentation-derived products, can potentially displace conventional ASFs. Cultivated meat, also known as lab-grown, cultured, or cell-based meat, is produced directly from cultivated animal cells, bypassing animal rearing and slaughter. Instead, the cultured cells are differentiated into muscle, fat and other tissues to replicate the properties of meat. Novel plant-based foods are formulated to mimic the taste and texture of animal products, and do not include traditional plant-based foods, such as tofu, tempeh or seitan. Fermentation-derived proteins use microorganisms, such as yeast and fungi, to produce biomass or specific animal proteins, including dairy and eggs.

These products could potentially provide nutritious foods with lower GHG emissions, land and water use, and biodiversity loss, compared to conventional animal-sourced food production (UNEP 2023; Alexander et al. 2017b), and also reduce the risk of zoonotic diseases (Santo et al. 2020) and antimicrobial resistance, and animal welfare concerns (van der Weele and Driessen 2013; Sexton 2019; Heidemann et al. 2020). However, the human healthimplications from these foods are uncertain (Hadi and Brightwell 2021; Cellura et al. 2021; Holmes et al. 2022), including allergenicity (Dong et al. 2024; Malila et al. 2024), and need further investigation.

The scale and the timeline of the adoption of alternative proteins remain uncertain, and widespread uptake is unlikely before 2030. Meanwhile, novel production methods and innovative technologies, such as vertical farming, precision sensing and monitoring technologies, agricultural robotics, on-farm automation and artificial intelligence, can increase the efficiency and sustainability of conventional food production (Poore and Nemecek 2018; Rubio, Xiang and Kaplan 2020; Javaid et al. 2023; van Delden et al. 2024).

The economic cost of producing cultivated meat and subsequent consumer prices are currently higher than conventional meat products (Chen et al. 2022; Kantor and Kantor 2021; Guan et al. 2021). While alternative protein prices in the medium term may approach parity with conventional meat, they are unlikely to compete with traditional plant-based proteins, due to the high costs associated with the construction and operation of production facilities. Lifecycle emissions may also be higher than plant-based foods due to embodied emissions in the infrastructure and the direct energy requirements, though likely lower than conventional ruminant meat (Alexander et al. 2017b). Using renewable energy for their production and processing could reduce their footprint. A key benefit over plant-based foods is that cultivated meats may be more acceptable to some consumers as a substitute for conventional meats (Sinke et al. 2023; Rombach 2022).

Multiple advanced technologies with potential to increase the sustainability and efficiency of food production are in development (De Clercq, Vats and Biel 2018; Popkova and Sergi 2023; McGrath et al. 2023; Haddad 2020; Rose et al. 2021). Vertical agriculture, using controlled-environment agriculture technologies to grow fruits, vegetables and crops indoors in vertically stacked layers, is producing foods commercially (Jaeger 2024). Artificial lighting, climate control, precision monitoring technologies, and automation are utilized to optimize plant growth, providing increased yield and requiring lower land use, natural resources, and agrichemical inputs. Other innovative production methods include hydroponics, aeroponics, and aquaponics, which all involve growing plants without soil and can be located in urban areas, reducing transportation emissions, distances, costs, and time. Other innovations are discussed in the agricultural efficiency solution pathway section (17.2.2), including remote monitoring and sensing technologies, livestock biosensing devices, farm automation technologies, agricultural robotics, and biotechnology.

To realize the potential of these technologies, greater investment in research and development is needed from national and international governments and the private sector. This includes more research into consumer acceptance (17.2.4.1) and financial support to scale up production facilities, establish supply chains, and facilitate commercialization (17.2.2.2). Regulatory regimes need to change to

Credit: JuiceFlair/Envato

enable widespread uptake of these novel foods and technologies (17.2.4.2). Changes to the financial incentives of the conventional meat industry, including educing subsidies for livestock production or taxing environmental externalities (17.2.1.1) could make conventional meat less price-competitive, and help novel foods and technologies to be price competitive. Socio-economic impacts should be considered to ensure equitable and inclusive benefits from novel alternative proteins, including supporting sectors that may be negatively affected by the shift from conventional ASFs (UNEP 2023). Widespread consumer adoption will depend on behaviour change, that could be supported by action contained in dietary change solution pathway (17.2.1), including trusted and tailored information, changes to social norms, and improvements in convenience and availability.

17.2.4.1 Drive advanced research and development in novel foods and production processes

While promising, the environmental and health impacts of many of these technologies are currently uncertain, with substantial development and research required to improve the technologies and understand their consequences fully. Internationally coordinated research programmes are needed to enhance flavour and nutritional value, reduce production costs, and evaluate the potential sociocultural impacts (Stephens et al. 2018; UNEP 2023). Both public and private investments are required to support this work. Research and development also need to address and mitigate associated trade-offs, such as the high energy demand of certain production processes (Sillman et al. 2020; Järviö et al. 2021; Odegard and Sinke 2021).

Widespread consumer acceptance will require integrating novel foods into global diets (Wilks et al. 2019; Kantor and Kantor 2021). Food neophobia, the reluctance to try unfamiliar foods, is a barrier, particularly for foods produced using new technologies that are often perceived as less natural than conventionally produced foods (Bryant et al. 2019). More research is required to understand consumer attitudes, including marketing strategies to achieve greater and rapid adoption post-commercialization, and identifying actions to inform (17.2.1.4) and shift social norms (17.2.1.5).

17.2.4.2 Changes to the regulation of novel foods

Efficient regulatory pathways are needed to enable the market entry of novel alternative proteins while upholding safety standards (UNEP 2023; Lanzoni et al. 2024). Integrating independent and transparent safety assessments is crucial, as similarities between novel and traditional products might not equate to identical safety or nutritional profiles (Holmes et al. 2022). Existing novel food approval frameworks may take considerable time to evaluate such products, and changes that reduce uncertainty in timeframes would support faster industry development (Good Food Institute 2022). Regulatory clarity around labelling and terminology would build consumer understanding and acceptance. This includes decisive positions on whether terms like "meat" and "milk" can be used for plant-based, fermentation-derived and cultivated products, with some evidence indicating these terms can help consumers understand the taste and use of these products (Gleckel 2020; Taylor 2020; Demartini et al. 2022). Finally, harmonizing international standards would facilitate global distribution of novel foods, helping producers create larger markets and attain economies of scale.

17.2.5 Solution pathway 5: Restructuring the food industry market structure and trade

A small number of transnational institutions dominate segments of the food system, such as agricultural commodity trading, intellectual property rights of animal and plant genetics, fertilizer production, and crop protection agrochemicals, which creates power asymmetries, and environmental and social costs (Wood et al. 2021; Sievert et al. 2024). Archer-Daniels-Midland, Bunge, Cargill and Louis Dreyfus control 70-90 per cent of the global grain trade. Bayer-Monsanto, Corteva Agriscience and Syngenta-ChemChina control around 50 per cent of the global seed market (United Nations Conference on Trade and Development [UNCTAD] 2023). The lack of institutional diversity raises potential concerns about the resilience of the food system to shocks (Davis et al. 2021; Moran 2020; Merkle et al. 2021), concerns of about excess profits (WHO 2024; IATP 2023; UNCTAD 2023) and the role of market power in unhealthy food consumption (Wood et al. 2021). Consolidation continues with dominant firms seeking leading positions in emerging digital platforms for agriculture, seed and agrichemicals, and vertically integrated supply chains. These transnational agri-food corporations are driving globalization of the food system, though the extent of an appropriate level of globalization in the food system remains contested.

Proposed solutions span the full range from returning to more local approaches (European Commission 2020) to maintaining or increasing globalization (Greenville, Kawasaki and Jouanjean 2019). Local food systems can promote biodiversity conservation, enhance soil health and water quality by supporting small-scale farmers to adopt more diverse and agroecological or traditional farming practices that preserve local crop varieties and protect ecosystems and support climate adaptation. But conversely, a globalized food system is better able to take advantage of the most efficient locations to produce foods and thereby achieve a greater overall efficiency. By specializing in the production of agricultural commodities based on their comparative advantages, countries can improve resource allocation and reduce overall environmental damage. Climate change adaption may reinforce globalization by changing the locations of areas where crops are grown (Alexander et al. 2018). Achieving self-sufficiency in all food categories within each region is often impractical, especially for countries with less suitable climates or limited arable land. Only a small proportion, between 11 and 28 per cent, of the global population could fulfil their food demands within a 100 km-radius (Kinnunen et al. 2020).

Reducing food miles can lower GHG emissions. However, transport accounts for only 4.8 per cent of food system GHG emissions, while 81 per cent comes from local to regional road transport (Crippa et al. 2021). While airfreight has the highest emissions on a per unit of mass and distance, emitting approximately 10 times more emissions for each tonne and kilometre of food transported than marine shipping, in total it contributes only 0.4 per cent of food transport emissions (Crippa et al. 2021). Local food systems are also promoted as a way to reduce the vulnerability from food supply chain disruptions originating in other locations. However, a reliance on local food is likely to increase exposure to local risks, such as crop failures, extreme weather, pests, or diseases. Additionally, prices for food commodities

produced and consumed locally are still influenced by global commodity prices (Hadachek, Ma and Sexton 2022). International trade typically enhances food system resilience to shocks, except when trade is directly impacted, such as during armed conflicts (Hamilton et al. 2020).

A balance between localized and globalized food system is likely to be most beneficial (Bajaj et al. 2025). However, current market structures often create lock-ins that hinder transformative change, with smaller actors being constrained by larger corporations, which may lobby policymakers against change. Despite these challenges, the power of these corporations could be leveraged to provide pathways for rapid transformations if aligned with consumer pressure (17.2.1.4-7), market incentives, subsidy changes (17.2.1.1-2; 17.2.3.4), and regulations (17.2.1.1; 17.2.4.1). However, socially beneficial transformations are less likely if corporate influence on policymaking goes unchecked, for example in an attempt to avoid damages to the vested interests of these corporations (Clapp 2021; WHO 2023; Wood et al. 2021). Greater transparency and accountability are required, alongside measures to foster a more equitable distribution of market power (Clapp 2021; UNCTAD 2023).

17.2.5.1 Joined-up and strengthened food system governance

Coordinated multinational policymaking is needed to regulate the transnational corporations operating in the global food system and ensure greater transparency (UNCTAD 2023). Inadequate regulation of corporate political involvement, such as lobbying, has allowed agribusinesses to partially capture of the regulatory processes in defence of their vested interests (WHO 2024). Governments need to strengthen regulations to curb corporate influence on political processes, including the need for greater regulatory coverage to prevent revolving-door practices, mandating disclosure of lobbying activities by industry associations, and requiring shareholder approval for corporate lobbying.

Incorporating environmental considerations into competition law can ensure that unsustainable practices, such as blocking collaborative sustainable initiatives, are face appropriate scrutiny, including being subject to competition law (Holmes and Meagher 2022). Governments can enhance and standardize corporate disclosure mandates, especially on environmental and social impacts. There is a need for greater global alignment, extending beyond climate reporting, to include nature-related disclosure, enabling meaningful and comparable transparency across jurisdictions.

Tariff and non-tariff barriers to international trade increase costs across the food system. While neither a localized nor a globalized food system is intrinsically more environmentally sustainable or healthier, trade in agricultural goods remains essential to the food system today. Protectionist measures, such as export bans, especially during food price shocks, often worsen price volatility (Alexander et al. 2023), and trigger retaliatory restrictions, leading to the same disruptions they were meant to avoid (Glauber and Laborde 2022).

Aligning trade policies with environmental and social objectives, using import regulations and customs duties, would promote international markets for sustainably produced goods and help uphold domestic policy targets. Adopting consumption-based accounting of emissions, rather than the current dominate approach which attributes emissions solely to producing countries, would reduce offshoring of emissions and avoid unintended consequences (Nielsen et al. 2021; Foong et al. 2022). Incorporating sustainable production and minimum food standards into bilateral or regional trade agreements can stimulate demand for healthier and more environmentally sound products. More broadly, greater governance integration is needed, aligning agriculture, health, environmental, and trade policies, supported by inclusivity measures and multi-stakeholder collaboration (Nicolini et al. 2023; UNEP, FAO, and UNDP 2023).

17.3 Combination of solutions to achieve the desired goals

This section outlines how each of the goals (Table 17.1) could be achieved through combinations of solution pathways (17.2). Combinations of pathways are essential to achieve the scale of the required transformation, while minimizing trade-offs and maximizing benefits.

17.3.1 Sustainable terrestrial and marine ecosystems

Achieving biodiversity and ecosystem goals (Table 17.1) while ensuring food security requires a multi-faceted,

holistic approach across food systems, employing a combination of solution pathways (17.2) and targeted actions. Transforming food systems through these pathways can halt biodiversity loss, prevent or reverse land degradation and improve soil health.

17.3.1.1 Halt biodiversity loss

Achieving the ambitious goals of reducing biodiversity loss to near zero in areas of high biodiversity by 2030 and cutting the extinction rates and risks tenfold by 2050 (**Table 17.1**), while ensuring food security, requires all of the solution pathways and their actions (17.2) to work in synergy. A holistic approach is essential, as different pathways and actions tackles different aspects of integrating biodiversity into the food system. Such holistic approaches will combine a multitude of approaches from production systems (17.2.2), market reforms to consumption patterns (17.2.1) creating the foundation for a sustainable food system that not only meets human needs but also conserves biodiversity and prevents mass extinctions. For example, shifting consumption patterns to sustainably sourced food (17.2.1) and improving food production efficiency (17.2.2), reduces the need for further land conversion, helping to maintain high-biodiversity areas and avoid habitat loss. Fisheries management approaches, such as modified fishing gear helps to minimize impacts on other marine species by reducing by-catch (Hilborn et al. 2023). Reducing production and consumption of animal-sourced foods and shifting to plant-based diets would lower agricultural land demand and reduce production intensity Henry et al. 2019; Harwatt et al. 2022). Protection and restoration of non-productive farmland, such as field margin, buffer strips, wetlands, peatlands, and permanent grassland, offers biodiversity and ecosystem service benefits (Pe'er et al. 2022).

Promoting sustainable healthy diets (17.2.1) through tax and subsidy reforms, combined with public awareness and education, alongside the development of novel foods (17.2.4), can steer consumer choices toward foods that balance nutritional requirements with biodiversity and environment protection (Delabre et al. 2021).

Promoting diverse foods and food cultures (17.2.1.6) helps preserve the genetic diversity of crops, livestock and fisheries cultivated for generations, supporting agroecological production systems that are closely tied to the environment and support the ecosystems underpinning agricultural productivity. For example, promoting millet in India, which is drought-resistant and requires less inputs, enhances grain diversity and reduces dependence on water- and fertilizer-intensive crops, like rice and wheat (Fischer et al. 2016). Similarly, encouraging consumption of food produced through traditional systems, such as milpa in Central America, which involves intercropping maize, beans, and squash, helps maintaining soil fertility and reduces the need for chemical inputs and sustains biodiversity (Romero-Natale, Acevedo-Sandoval and Sanchez-Porras 2024; Gonzalez Alvarez, Koohafkhan and Ahagarodsky 2023).

Strengthening the focus on Indigenous and local food systems and knowledge (17.2.3.4) can help preserve agrobiodiversity and valuable ecosystems (Kennedy et al. 2022). This knowledge and these systems have evolved over centuries to manage and produce various crops, livestock and aquatic species. Agrobiodiversity enhances food, economic and climate resilience by diversifying income sources, stabilizing food supply, and improving adaptability to climate extremes (Altieri et al. 2015; Ickowitz et al. 2019). Local and Indigenous Knowledge and food systems often align with preserving natural ecosystems and landscapes. For example, in the Amazon rainforest, Indigenous agroforestry systems incorporate diverse crops and trees that mimic the natural forest structure, supporting soil health, biodiversity and maintaining ecosystem functions (Rodriguez et al. 2021).

Establishment of marine and terrestrial protected areas (17.2.2.6) can safeguard critical ecosystems and has historically contributed to biodiversity conservation (Pe'er et al. 2022: Harwatt et al. 2022). Protected areas, like national parks, wildlife reserves, and marine sanctuaries, protect species diversity, maintain ecological processes, and buffer against land-use changes that threaten species extinction. Circularity, nutrient recycling, and food waste reductions decrease the need for resource extraction and agricultural expansion, conserving biodiversity. Shifts in societal perceptions and market reforms that encourage the consumption of sustainably farmed fish or shellfish support food security by providing a reliable source of nutrition, while also reducing

Credit: ©UNEP

overfishing and minimizing ecosystem degradation (Smith et al. 2022).

Finally, strong governance, investments and incentive mechanisms are essential for overcoming social, economic and institutional barriers to mainstream biodiversity conservation in food systems. This includes aligning food market and trade policies with zero-deforestation goals, particularly in sectors like soy, palm oil and beef (Ortiz et al. 2021). Investment in nature-based solutions, such as the sustainable farming incentives (Harwatt et al. 2022) and the EU's Farm to Fork Strategy (Pe'er et al. 2022; Harwatt et al. 2022), offer financial support for farmers who adopt biodiversity-friendly practices. In fisheries, area-based management, such as seasonal, temporal or permanent closures of specific fish species, can help address trade-offs between sustainable fishing and biodiversity conservation (Hilborn et al. 2021).

17.3.1.2 Prevent and reverse land degradation and improve soil health

Many solution pathways and actions explained above (17.2) can help prevent land degradation and improve soil health, including enhancing soil carbon sequestration. When integrated in a cohesive strategy, these solution pathways and actions can support land degradation and soil health goals (**Table 17.1**) to maintain and restore soil health by increasing soil organic carbon and microbial diversity, to achieve land degradation neutrality by 2030, restore 30 per cent of degraded land by 2030, and increase soil carbon levels by 12 per cent by 2050.

Advancing research and innovation for sustainable intensification of crop, livestock and fisheries production systems (17.2.2.1) helps generate the practices that restore degraded soils, enhance soil organic matter and improve overall soil health. For example, conservation agriculture based on the principles of no-till farming, permanent soil cover and appropriate crop rotation improves soil health, increases carbon sequestration (Sapkota et al. 2017), reduces erosion, and increases water retention (Lal 2015). Similarly regenerative production practices such as agroecology and permaculture, help restore soil health, increase biodiversity, and enhance ecosystem resilience

Indigenous communities often possess a deep understanding of their local ecosystems, which have developed over generations. Increased focus on such systems and knowledge preserves these valuable knowledge systems and promotes long-term soil conservation and stress resilience. For example, the traditional *Zai* technique, used by farmers in the Sahel region, involves digging small pits to capture

rainwater and concentrate organic matter, which enhances soil moisture and nutrient availability in otherwise arid environments (Tamagnone et al. 2020). Similarly, pastoralists in Eastern Africa use water pans and well excavation during droughts to ensure water availability for their livestock (Nkuba et al. 2019).

Adopting a systems-thinking approach enhances the interconnections between food systems, land management, and soil health, enabling the development of more holistic solutions. Nature-based solutions, including reforestation, wetland restoration, and the establishment of protected areas (17.2.2.6), can safeguard critical ecosystem services. At the same time, transitioning to circular and regenerative agriculture (17.2.3) can restore degraded soils, improve soil organic matter, and enhance carbon sequestration.

Redirecting financial support (17.2.2.2; 17.2.2.4) away from agrochemical-intensive production systems towards practices that encourage regenerative agriculture (Giller et al. 2021), crop rotation, and reduced chemical inputs can help improve soil health (Peeters et al. 2020). Healthier soil improves water retention and nutrient cycling, which are essential for ecosystem services, biodiversity, and long-term agricultural productivity (Peeters et al. 2020). Such reforms would benefit the environment and offer farmers long-term economic gains by reducing their dependency on expensive chemical inputs and improving crop resilience to climate variability.

17.3.2 Climate change mitigation

The solution pathways and actions detailed in section 17.2 support the transformation of food systems in ways that contribute directly to the climate mitigation goals (**Table 17.1**), including achieving net CO_2 neutrality, reducing CH_4 and N_2O emissions, and enabling land-based mitigation strategies. As bioenergy, afforestation, reforestation, and other land-based mitigation options compete for land with agricultural production (Muscat et al. 2020; Perkins et al. 2023), increasing productivity on existing farmland through sustainable practices, reducing waste, and shifting towards plant-based diets can reduce pressure on land and free up space for land-based mitigation solutions, turning the food system into a carbon sink (Cost Jr et al. 2022; IPCC 2019; Poore and Nemecek 2018). Studies estimate that plant-based diets alone could reduce agricultural land use by up to 76 per cent (Poore and Nemecek 2018).

Reducing the intensity of meat and dairy consumption, especially in high-income countries, and promoting plant-based diets rich in coarse grains, pulses, fruits, vegetables, nuts, and seeds can cut GHG emissions from the food system by up to 49 per cent (Poore and Nemecek 2018). These changes can be achieved through changes in food industry practices and regulations (17.2.1.2, 17.2.2.5), taxes and subsidies to reflect true environmental costs of food (17.2.1.1), producer and consumer awareness campaigns (17.2.1.4), and promotion of local and traditional food systems. The global mitigation potential of such dietary shifts is estimated to be 0.7-8.0 $GtCO_2$-e annually by 2050 (IPCC 2019).

Similarly, investing in agricultural innovation for improved crop management, optimized fertilizer and water use can reduce nitrous oxide and methane emissions. Sustainable intensification of crop, livestock and aquatic production systems through advanced research and innovation in genetic improvement and management systems (17.2.2.1) helps reach the climate change mitigation goals by increasing carbon sequestration and reducing GHG emissions (Herrero et al. 2016; Campbell et al. 2016; Carlson et al. 2017). Circular and closed-loop production systems, which recycle resources and reduce reliance on external inputs, such as synthetic fertilizers and energy-intensive production processes, further lower GHG emissions. Similarly, promoting local food systems can reduce long-haul transportation and refrigeration emissions.

Reforming finance and policy mechanisms is essential to transforming food systems toward low-emission pathways and achieving climate goals. Shifting agricultural subsidies (17.2.2.4) away from input-intensive practices, such as fertilizer subsidies in high-intensity production systems, toward sustainable practices, and strengthening Indigenous systems (17.2.2.6), can foster more carbon-efficient farming, reducing agricultural emissions. Financial mechanisms, like payments for ecosystem services, low-interest loans, green and blended finance, and carbon credits, can accelerate the adoption of clean technologies, including precision agriculture, renewable energy, and low-emission innovative mechanization. Similarly, flexible, scalable, and accessible financing mechanisms, such as Pay-As-You-Go and pay-for-service models, help

overcome upfront cost, enabling greater adoption of sustainable practices in low-income regions. The application of these financial mechanisms in food systems is still limited, but they have the potential to grow (Wattel et al. 2024).

Policy reforms and incentives, such as subsidies for sustainably sourced products and taxes on carbon-intensive goods, can drive market transformation, supporting climate mitigation.

Finally, tackling food loss and waste—which contribute 8–10 per cent of total anthropogenic GHG emissions (IPCC 2019)—can reduce emissions and improve food security. This can be achieved by improving harvesting and storage, raising awareness, and promoting behavioural change to support greater circularity (17.2.3).

17.3.3 Human health and wellbeing

The lack of progress on eliminating global hunger (SDG2) and malnutrition (7.2.2, 17.1), can only be addressed by making healthy and environmentally sustainable food accessible and affordable for all. Currently, largely affordable and accessible around the world are too often ultra-processed foods. These foods are high in sugar, salt, unhealthy fats, industrial additives, and preservatives, contributing to poor health, including obesity (Valicente et al. 2023; Askari et al. 2020). Poor global nutritional outcomes have multiple causes and exacerbating factors, including climate change and conflict (FAO 2023a). However, the key challenge lies in misaligned incentives for food system actors to deliver healthy, safe and diverse, accessible and affordable diets for all (Herforth et al. 2021; Wood et al. 2021).

Lower food prices can appear to be a solution to malnutrition, but evidence from the past 60 years suggests otherwise. Despite food productivity outpacing population growth, with 34 per cent more cereal per person in 2022 than in 1961 (FAO 2024) and decreasing real terms food prices, the rate of undernutrition remains high and is now coupled with a rapid rise in obesity. Increasing food production and declining prices have led to unhealthy overconsumption and environmental degradation, a form of Jevons Paradox (Alcott 2005). A continued focus on lowering food prices through increased productivity is likely to see these damaging trends persist (Hendriks et al. 2023).

Consumer practices and food production changes are required, leveraging all five solution pathways. Agriculture and fishery policies and research must shift from being focused on increasing the yield and providing consumers with low nutrient density calories to being focused on providing nutritious and more sustainable foods (solution pathway 2). This includes diversifying food production and minimizing environmental harm from agricultural expansion and input-intensive production (17.2.2).

Consumption preferences need to shift away from diets high in meat and processed foods, using a mix of education, market reforms and pricing policies (17.3.1). Reducing demand for environmentally intensive food will also require cutting food system losses and waste, including lowering losses across the supply chain, and achieving greater nutrient circularity (17.2.3). Alternative proteins, novel plant-based foods, cultivated meat, and fermentation-derived products may also play a role in addressing the high demand for ASFs (Sexton et al. 2019) (17.2.4). The food industry will play a principal role in facilitating healthier consumption patterns, calling for realignment of industry incentives (17.3.4) and voluntary industry actions (17.3.5).

Food prices that reflect health and environmental costs and benefits will be central to achieving the transformation. Reforming agricultural taxes and subsidies to prioritize public good and discourage the production of environmentally damaging foods is necessary (17.2.2.4). This alone is unlikely to be sufficient. Therefore, consumer taxes and subsidies on foods are needed to reflect their true food costs (17.2.1.1). Such changes would make many foods, and especially animal-sourced foods, more expensive. Stronger social protection and security nets, including welfare payments or other supports for the poorest, will be essential to avoid damaging vulnerable households and ensuring that their nutritional needs are met. In combination, these reforms could be pro-poor and reduce inequalities. Ultimately, to make healthy food affordable for all, we need to address poverty, rather than making the current, often unhealthy food, cheaper.

17.3.4 Equitable livelihoods

Equitable livelihood goals (**Table 17.1**) require fair treatment of workers across the food systems,

improved social justice, recognition of Indigenous rights and knowledge, as well as local knowledge, and support for diverse food cultures. Good working conditions, dignity and fair wages for food system workers contribute to productivity and safety at the farm and industry level (Ramos et al. 2021). Empowering communities to produce their food can be beneficial. In addition, farmer organizations should amplify the community's voices on various platforms to eliminate social injustices and promote inclusion. Social security, higher wages, healthy living, safety nets and gender equality are all critical to ensure equitable livelihoods and food system transformation (Reynolds et al. 2016).

Sustainability and justice in food systems are also reinforced by the realization of human rights (e.g., the right to a clean, healthy and sustainable environment, UNGA A/RES/76/300), Indigenous rights (e.g., the collective rights to lands, territories and resources, UNDRIP), the rights of peasants and rural workers (e.g., the right to determine their food and agriculture systems, and to participate in decision-making processes on food and agriculture policy, UNDROP).

Sustainable and just food systems also require supporting local food production and consumption, integrating lived experiences to inform food production, and recognizing consumer-led local food initiatives. Indigenous Knowledge forecasts enhance the adaptive capacity of arable farmers (Nkuba et al. 2020) and pastoralists (Nkuba et al. 2019). Investing in education and work opportunities in rural communities, many of which suffer from youth outmigration, can encourage younger farmers to stay in these regions, thus preserving generational knowledge and traditions.

Local and diverse foods can offer healthy, affordable and nutrient-dense options, while promoting more sustainable and lower-impact harvest and production methods (including fisheries and aquaculture) that are rooted in traditional, Indigenous, or small-scale practices, would help to reduce negative environmental impacts while also supporting socioeconomic objectives (17.2.2). These can methods create jobs, enhance the interconnections and knowledge exchange among local food producers, improving sustainability outcomes (Ajayi et al. 2021; Soma et al. 202). However, local food systems often face limited market access, inadequate social capital, unfavourable government policies, restricted funding, and minimal access to appropriate technology. Government support, prioritization of local foods as part of an adaptation strategy and strengthening of farmer networks can help address these challenges (Carter 2022).

Restructuring the global food system requires actors to adopt innovative tools, embrace sustainable practices, organize sustainable supply chains, revamp marketing, and create shared value along the food value chain. Collaboration between the public and private sectors is crucial for promoting agroecological practices, sustainable procurement, and the empowerment of local food producers (Stahlbrand 2017). Education can help spread best practices, raise awareness on causes and impacts of inequalities, share success stories, and identify future areas for development, while farmers' narratives can inform decision-making (Breen and Muller 2020).

17.3.5 Resilient to shocks and stresses

A resilient food system can withstand and recover from disruptions, while maintaining functionality and providing sustainable and equitable access to nutritious food (de Steenhuijsen et al. 2021; Zurek 2022) (**Table 17.1**). This is one of the food system goals. Disease outbreaks (including the COVID-19 pandemic (Moran et al. 2020), climate changes, weather extremes, and geopolitical events have affected the food system, and will likely do so more severely in the future (Hamilton et al. 2020; Jones 2023). These disruptions range from sudden shocks to gradual long-term stressors, like pollution and climate change. Progress towards the Sustainable Development Goals has been slowed, if not reversed, by recent events such as the global financial crisis in 2008-2009, 2011-2012, the Covid-19 pandemic, and Russia's invasion of Ukraine (FAO et al. 2024; UNDESA 2023).

When food system operations are disrupted, whether through damage to agricultural production or constraints on international trade, food prices rise, leading to disproportionate harms for the poorest, including increased malnutrition and associated mortality (Alexander et al. 2023). This highlights the need to provide social safety nets that ensure sufficient income for a healthy diet (Fan 2021) (17.2.1.1). To

increase food system resilience a level of supply chain redundancy and elimination of single sources of failure across the supply chain is needed. Local or national self-sufficiency does not necessarily increase resilience and still exposes consumers to global market price shocks. So, maintaining a combination of domestic production with open access to international markets is likely be beneficial (17.2.4.1). Diversity in food industry structure and supply sources enhances food system resilience (17.2.5). This includes avoiding harmful policy responses, such as export bans and restrictions in response to trade shocks or price fluctuations (Fan 2021).

Resilience in the food system can only be achieved with climate-resilient production, capable of withstanding weather extremes, pests and diseases (FAO 2021). While adaptation of agriculture to future climate and weather extremes is essential, climate-smart agriculture and fisheries approaches (African Union Development Agency 2021), should go hand-in-hand with agroecological approaches that build resilience (17.2.2). While some events are likely to reduce productivity for some crops and locations, the risks to the food system more widely can be mitigated by having a diverse system, at all levels (Nicholson et al. 2021; Eisenhauer 2023). Diversity in production includes increasing the diversity of species, crop varieties and animal breeds. Current trends are moving in the opposite direction, with a homogenization in crop varieties and animal breeds (Khoury 2014; McCouch 2023; Gruber 2017). Actions are needed to increase the diversity of food produced, including expanding the use of orphan or opportunity crops and Indigenous or locally adapted species (Renard and Tilman 2019; Talabi 2022; Zuza et al. 2024) (17.2.1.6).

17.4 Implications of the solution pathways on the other systems

There are strong interconnections between energy (Chapter 16), environmental (Chapter 18) and food systems due to shared demand for land and other resources (IPCC 2022b). Land use is key to the energy transition and climate change mitigation, with large areas being projected for carbon dioxide removal using bioenergy with carbon capture and storage in many scenarios (Chapter 16) (Perkinset al. 2023). At the same time, transformations in the food system place additional demands on the energy system. For example, large-scale adoption of some novel foods or novel production processes, including cultured meat, will likely require cheap, low-carbon energy for net positive environmental outcomes (UNEP 2023). Land protection and use for biodiversity conservation is also increasing, with targets for 30 per cent of land to be protected by 2030 (Convention on Biological Diversity 2022) and support for the Half-Earth Project, advocating for 50 per cent of the planet being protected for nature (Chapter 18), with implication for the food system (Henry et al. 2022).

Competition for water is also intensifying, increasing linkages between energy, environment and food systems (Chapters 6, 10, 11). Climate change is reducing water availability while increasing demand for agricultural use. Irrigation is an effective adaptation approach in agriculture and can be used to increase productivity (IPCC 2022a). Additionally, water demands continue to increase for industrial use and as populations grow and urbanize (Chapter 2). Resulting unsustainable water extraction and pollution leads to biodiversity loss and impaired freshwater and marine ecosystems functioning. The food system is central to solving these issues, with 70 per cent of water withdrawals used for agriculture today as well as fertilizers and animal waste being a key source of nutrient runoff, leading to eutrophication. However, agricultural adaptation and the transformation of the food system are also heavily constrained by sustainable water availability. Coordinated actions and adoption of technologies that improve irrigation and water use efficiency are needed to reducepollution of aquatic ecosystems and help preserve water stocks (17.2.2).

Agrochemicals production and use add further cross-system interactions. For example, fertilizer production heavily relies on fossil fuels, with over 100 million ton of inorganic nitrogen fertilizers produced annually. While some reductions in total fertilizer use may be possible through the solution pathways described here, providing sufficient food will still require inorganic fertilizers. Therefore, green ammonia and other renewable and low-carbon fertilizers will be required, increasing demands for renewable energy (Ch16). Phosphate fertilizers production also relies on fossil fuel derivatives, like sulphur (Day, Alexander and Maslin 2024). Both potassium for potash and phosphate fertilizer

production cause substantial environmental damage (Chapter 18).

Changes in the economic system (Chapter 14) and materials/waste (Chapter 15) are critical to achieving the transformation of the food system. Internalizing externalities (14.3.1) to achieve prices that reflect the true cost across the economy is vital, and this applies strongly to the food system, where both environmental and health outcomes from foods should be reflected in their pricing (17.3.1.1). Reforming subsidies and financial mechanisms is also essential to enable the transformation (14.3.2; 17.2.2.4). Similarly, the transformation must reduce losses and increase circularity at all stages of the food system, from production, transport, processing, retail and at the consumer (15.2.1; 15.2.4; 17.3.3).

The need for cross-system coordination between food and other systems, particularly the energy system, is made clear by the results of the modelled transformation pathways (Chapter 11). Achieving climate mitigation targets in these scenarios heavily relies on bioenergy, with energy crop production projected to be 3-5 times larger than in the current trend scenario. In these scenarios, energy crops account for 15 per cent of crop production in the Technology-focused Transformation pathway and 22 per cent in the Behaviour-focused Transformation pathway. Expansion of forests and other natural areas, for enhanced ecosystem functioning and to support biodiversity, further intensifies competition for land. On the current trends pathway, this area contracts, while it expands substantially by 2050 in both modelled transformation pathways – with an additional area of 670 million hectares in the Technology-focused Transformation pathway and 380 million hectares in the Behaviour-focused Transformation pathway.

Dietary change plays a key role in both the Behaviour-focused and Technology-focused Transformation pathways (Chapter 11). In the Behaviour-focused Transformation pathway, global per capita demand for ASFs drops by 44 per cent by 2050 due to shifts in preference (17.2.1), but even in the Technology-focused Transformation pathway, ASF consumption drops by 17 per cent due to pricing of externalities (17.2.2) and substitution with alternative proteins (17.2.4).

In both transformation pathways, agricultural yields increase, 41 per cent in the Behavioural-focused Transformation pathway and 46 per cent in the Technology-focused Transformation pathway, from 2020 to 2050 (17.2.2). This is accompanied by production methods using fewer inputs, lowering environmental harms. For example, by 2050 water withdrawal for irrigation drops by 20 per cent and 11 per cent, respectively, compared to the reference scenario. Additionally, food loss and waste are also substantially reduced, with 28 per cent and 32 per cent reductions in food waste rates, respectively, in these scenarios (17.2.3). These modelled scenarios underscore the need to transform food production and consumption and the need for cross-system changes.

Many policy requirements are seen as politically challenging. Measures like meat taxes and the true cost of food often face public resistance. While environmental awareness is rising, social acceptance is emerging too slowly relative to the urgency of the environmental crisis. Food is a sensitive subject, deeply embedded in culture, and there is a risk of backlash and resistance from citizens.

Chapters 12, 13 and 21 discuss addressing the interacting transformation challenges. In the specific context of the food system, education, awareness raising, and collective actions need to increase acceptance and demand for changes in governance of the food system, as well as to directly impact the food system through individual actions related to foods consumed. Implementing these solutions on a scale sufficient to address the issues and constraints faced by food systems is challenging. To move towards large-scale food system transformation, a high level of political commitment and tailored solutions adapted to specific regional needs and local socio-economic realities.

A successful transformation across energy, environmental and food systems require a coordinated and integrated approach. Part of this will be minimizing the land use of the food system, to allow enough space for ecosystem functioning, biodiversity conservation, and climate mitigation. This will require strategic implementation of the solution pathways and actions described in this chapter.

Chapter summary

Credit: Shaiith/Envato

The global crises of climate change, biodiversity loss and pollution, together with land degradation, are putting both people and nature at risk by pushing the environment system beyond six out of nine planetary boundaries, which are critical for maintaining a safe operating space for human existence *(very well established)*. Sustainable development requires that society works together through action across social, technological, political and economic levers to build a resilient, culturally meaningful, and sustainable environment system. This also means transforming how production and consumption of energy, food, and resources in circularity and management economic and financial systems are carried out *(established but incomplete)*.

Three overarching goals with significant transformative potential to support nature, alongside circularity, energy and food systems are identified:

- strengthen the nature-society-economics nexus enabling integrated ecological health with an inclusive social and economic well-being

- adopt transformative adaptation of socioecological systems for climate resilience and delivering enhanced benefits to nature and people

- restore natural capital through a sociotechnological approach to enable sustainable bioeconomy to substantially reduce pressures on ecosystems and biodiversity.

A sustainable and resilient environment, delivering for both humans and nature, can be achieved, but only if management of natural resources changes. This means using less, wasting less, and protecting valuable ecosystem services, such as clean water and air and healthy soils. To do this, the solutions need to be fair and inclusive, and shaped by the knowledge of Indigenous Peoples and local communities *(established but incomplete)*. Internationally agreed goals for addressing climate change, reducing biodiversity loss and stopping pollution, cannot be achieved without a transformative approach to environmental protection and management *(very well established)*. In GEO-7, earlier chapters present methods and solutions for transforming four key human-controlled systems: economic and financial, circularity, energy, and food. Building on these insights, this chapter develops a narrative to create a sustainable and resilient environment system, outlining clear goals and the solutions needed to address the challenges of global crises. These goals are reached through a series of solution pathways, which involve specific actions carried out across different time frames and scales and by various actors.

The first goal is to strengthen the alignments among nature, society and the economy through sustainable land use, green infrastructure, climate change adaptation, and sustainable consumption. {18.1} This integrated systems approach supports ecological health, social inclusion, and economic well-being, enabling a balance across all systems *(established but incomplete)*. Implementing these actions can enhance biodiversity across urban, rural, and marine areas, while supporting vital ecosystem services that benefit both people and nature. They also align with key global frameworks, including the One Health approach, the 2030 Sustainable Development Agenda, the Paris Agreement, and the 2022 Kunming-Montreal Global Biodiversity Framework (GBF) *(well established)*.

The second goal – transformative adaptation – will alleviate the worsening effects of climate change and build future resilience of socioecological systems across land and sea. {18.1} Without effective climate change adaptation (CCA), progress on biodiversity conservation and restoration, food security, and community resilience is at risk *(well established)*. There is an overwhelming scientific consensus that transformative adaptation is needed, rather than incremental steps (UNDRR 2015; IPCC 2022). Rapid scaling up of locally led adaptation (LLA) actions and disaster risk management (DRM) is crucial for driving transformative adaptation, while minimizing loss and damage from extreme climate events and complex multi-hazard emergencies.

The third goal is to restore natural capital by substantially reducing pressures on ecosystems and biodiversity. This will help to halt ecosystem degradation and support conservation goals and targets, including the targets of the GBF, such as the 30 x 30 target to conserve 30 per cent of the world's land and oceans by 2030, in line with the human rights-based approach. {18.1} *(established but incomplete)*. The circular economy plays a key role in restoring natural capital by moving away from the traditional linear model of "take, make, dispose". It promotes recycling, reusing, refurbishing and sharing products to minimize waste and reduce the extraction of new resources. Innovative biobased materials, such as biodegradable products derived from agricultural waste and perennial feedstocks, offer sustainable alternatives to fossil-based products. Scaling up bioeconomy infrastructure, including biorefineries and supply chains for biobased products, is essential for using renewable biological resources at a larger scale. Efficiently managed protected areas is another vital component of the GBF 30 x 30 target, though it remains a challenge for many regions. When successfully implemented, it can significantly improve ecosystems' resilience and health. Regional policies, legislations and initiatives are needed to promote nature restoration and sustainable land use.

We identify five solution pathways to enable a sustainable and resilient environment system. {18.2} The first is conserving ecosystems and biodiversity, including sustainable land management practices. {18.2.1} The second is widescale implementation of nature-based solutions (NbS). {18.2.2} The third is upscaling LLA. {18.2.3} The fourth is accelerating a biobased circular economy. {18.2.4} The fifth is expanding integrated solutions through strong governance, local community

engagement and inclusion of Indigenous Knowledge and Local Knowledge {18.2.5}.

These solution pathways are complex and involve trade-offs, but they also offer co-benefits that help nature, energy and food systems to be more resilient, while enabling circular economies in the future *(established but incomplete)*. They are aligned with the ambitions of the GEO-7 target seeking scenarios, that in different ways, particularly with respect to land use, enable ambitious global targets for the environment to be met.

The first solution pathway – protection and conservation of ecosystems and biodiversity – is critical for the planet's overall sustainability and the implementation of the ambitious 30 x 30 target of the Global Biodiversity Framework *(very well established)*. The target seeking scenarios of GEO-7, show that ecosystem protection, conservation and restoration require faster, more coordinated efforts that combine a wide mix of proven and innovative approaches to manage environmental drivers and pressures. These efforts are aimed at improving both the quantity and quality of natural capital and ecosystem services. Successful actions could include NbS, regenerative production systems, expanding and connecting protected areas to form biodiversity corridors, and strengthening pollution control, including plastic waste {18.2.1}.

Analysis of the two GEO-7 target seeking scenarios illustrates that protection of existing ecosystems, restoration of degraded lands and improved land management are crucial to preserving biodiversity, halting land degradation, and increasing carbon storage *(well established)*. Both target seeking scenarios envision an increase in protected areas, ranging from 30 per cent with strict protection to 50 per cent with more symbiotic relations between humans and nature. This strongly contributes to preventing the conversion of natural land and increases the possibilities of tackling biodiversity loss. Furthermore, conservation and expansion of natural lands enables them to act as important carbon sinks and thus contribute to climate change mitigation, while improving natural capital {18.2.1; 18.2.1.2; 18.2.1.3}.

The second solution pathway involves broad adoption of NbS, which offers a holistic strategy to foster a resilient and sustainable environment. This facilitates systems transformation, with many practices already recognized and implemented worldwide *(well established)*. However, NbS need to be scaled up significantly to unlock greater systems transformation. {18.2.2} This includes expanding ecosystem restoration, strengthening climate resilience, and maximizing co-benefits across socioecological systems. As a broad approach, NbS works across sectors and actions – including enhancing ecosystem services, regenerating food and energy systems, implementing green infrastructure, promoting sustainable agriculture, applying ecosystem-based adaptation (EbA) and disaster risk reduction, expanding and interconnecting protected areas to create biodiversity corridors, and using NbS for greenhouse gas mitigation through biogeochemical carbon capture {18.2.2}.

By definition, NbS are balanced and cost-effective approaches that can build on Indigenous Knowledge and Local Knowledge *(incomplete)*. They aim to enhance ecosystem services by supporting and improving both natural and human-made systems. However, the choice and implementation scope of NbS must be tailored to the local conditions to ensure the interests and the well-being of local communities are protected, while preserving the integrity of natural ecosystems {18.2.2.3}.

The third solution pathway integrates approaches for socioecological resilience through scaling up LLA and DRM with a multi-hazard perspective. This solution narrative is crucial for driving transformative adaptation and minimizing loss and damage to both humans and nature across land, island, and marine environments *(well established)*. LLA draws on the wealth of knowledge and experience of the Indigenous Peoples as well as local communities, while incorporating robust DRM to address the increasing challenges of unprecedented multi-hazards.

A combination of bottom-up and top-down adaptation strategies can leverage Indigenous Knowledge and Local Knowledge to promote innovation. This approach ensures that solutions are culturally suitable and have community support, which is essential for their long-term effectiveness {18.2.3}.

The fourth solution pathway enables the acceleration of circularity by developing innovative sustainable biomass feedstocks and building a sustainable bioeconomy infrastructure. This shift aims to replace fossil fuel-based supply chains and support a resilient and sustainable environment in the future *(well established)*.

Transitioning to circularity and a sustainable bioeconomy is a significant step towards reducing reliance on

fossil-based energy, food production, materials, pharmaceuticals, and chemicals, with 23 countries with bioeconomy strategies and 15 others in development. In the EU, 130 woody biomass-based biorefineries are in operation, with more planned. Both of the GEO-7 target seeking scenarios identify sustainable biomass as a key part of achieving a transition to a low-carbon energy system, consistent with the Paris Agreement, with the behaviour-focused enabling a sustainable environment system for people and planet. This transformation requires a significant increase in biobased and microbial resources, while managing land, oceans and waste streams more responsibly and in harmony with nature (well established). Emerging technologies, such as bioengineering of new plant, animal and microbial resources, can enable the production of high-value chemicals, pharmaceuticals, energy, fuels, climate change mitigation and materials, as well as new types of engineered foods and medicines *(incomplete)* {18.2.4}.

The fifth solution pathway is establishing a strong adaptive governance to integrate the four other solution pathways across economic and financial, food, energy, and circularity systems. This approach enables adaptive decision-making and the balancing of multiple priorities, laying the foundation for scaling up and expanding the sustainability transformation *(established but incomplete)*. While these solutions are already known, they are poorly connected, inconsistently implemented, and ineffective without strong governance. Adaptive governance can play a crucial role by connecting local communities and integrating Indigenous Knowledge and Local Knowledge with national policies for biodiversity conservation, CCA, and the bioeconomy transition. This integrated approach could be instrumental for addressing the key drivers and pressures of environmental systems {18.2.5}.

The success of these transformative solution pathways relies on how quickly tools and actors, both government and non-government, are put into coordinated action across different levels and scales of socioecological and sociotechnological systems. Action is needed to activate key enabling levers using the new framework of GEO-7, aligned to approaches outlined in the target seeking scenarios. If actions are not coordinated soon, society risks irreversible setbacks, so renewed efforts are required to overcome the challenges and put key levers into motion, (inconclusive). In the short term, knowledge and innovation levers can improve the monitoring of the environment and biodiversity, enhance pollution and waste control, and make a better use of technologies *(unresolved)*. These can be combined with individual actions and group decision-making levers, as well as financial and economic levers, to create new financial and governance mechanisms that recognize the value of ecosystem services, all supported by institutional and policy levers. For ecosystem and biodiversity protection and conservation, both target seeking scenarios of GEO-7 envision pathways to increase protected areas, ranging from 30 per cent to 50 per cent. New knowledge and technologies required in the short term should be combined with the individual actions and group decisions and the financial and economic levers for new mechanisms to value ecosystems services, underpinned by governance levers. {18.2.1}.

Evidence from science, policy, and practice demonstrates that NbS can be a powerful way to restore ecosystems when they are designed around people's needs. Effective NbS efforts must involve key stakeholders, representing social and cultural diversity, as well as institutions and governance structures that hold knowledge assets and help guide decisions. For NbS to succeed, they must be tailored to the local context, based on solid evidence, well integrated into wider plans, be fair and inclusive, and shaped by transdisciplinary inputs. To make this happen, increased engagement through individual and collective action is necessary. In the short term, the focus should be on increasing knowledge, encouraging innovation, and strengthening institutions and governance. Building skills and capabilities will also be important to support a successful transition in the medium to long term. Once this foundation is in place, the next step would be to update financial, economic, institutional, and governance systems to make the most out of these innovations, especially those based on computational and data-driven approaches, biobased discoveries and novel engineering solutions. Valuing environmental goods and ecosystem services while advancing the circular economy will be central to this phase {18.2.2}.

The success of transformation will depend on how effectively and quickly levers and actors can be mobilized across scales and diverse socioecological systems *(established but incomplete)*. Local communities, including vulnerable groups, youth, women, older people, and Indigenous Peoples, play a central role as custodians of socioecological

systems (SES) and as those directly reliant on ecosystem services. Their leadership is crucial in planning and executing enabling solutions, which can be strengthened by new technological innovations in monitoring and data. Other actors, including the public and private sector at local, national and international levels have key supporting and networking roles. They help provide access to technology, finance, and capacity needed to ensure the success of the adaptation efforts {18.2.3}. In the short term, the use of enabling technologies, like sensors and AI-based computations, will support sustainable land and ocean management to sustainably increase bioresource production and supply to facilitate a circular bioeconomy. This will require science and technology, in partnership with strong institutional and policy actions to ensure governance of trade-offs with land for food, energy and nature. In the medium to long term, developing a newly skilled workforce with new knowledge and capabilities in biology, chemistry, engineering and infrastructure, as well as new finance, economics, and strong institutions, will be crucial for scaling up infrastructure and achieving as future sustainable bioeconomy {18.2.4}.

Across all timescales, from short to long term, building capabilities and encouraging both individual and collective action will be essential, especially as new stakeholder groups and social systems emerge around the transformed environment system.

A resilient and sustainable environment is the foundation of transformative change across nature, food, energy, finance and the delivery of a circular economy – key to addressing the global environmental crises *(well established)*. This chapter outlines a road map with clear signposts through a set of goals, solution pathways and key actors to enable future success. A common theme across all solution pathways is that early actions require new technologies to be harnessed in monitoring, assessment and data-driven approaches, linked to locally-engaged individuals and communities. These actions should be underpinned by innovative financial and policy instruments. and in the long term, capacities and skills development.

Credit: bilanol/Envato

18.1 Introduction

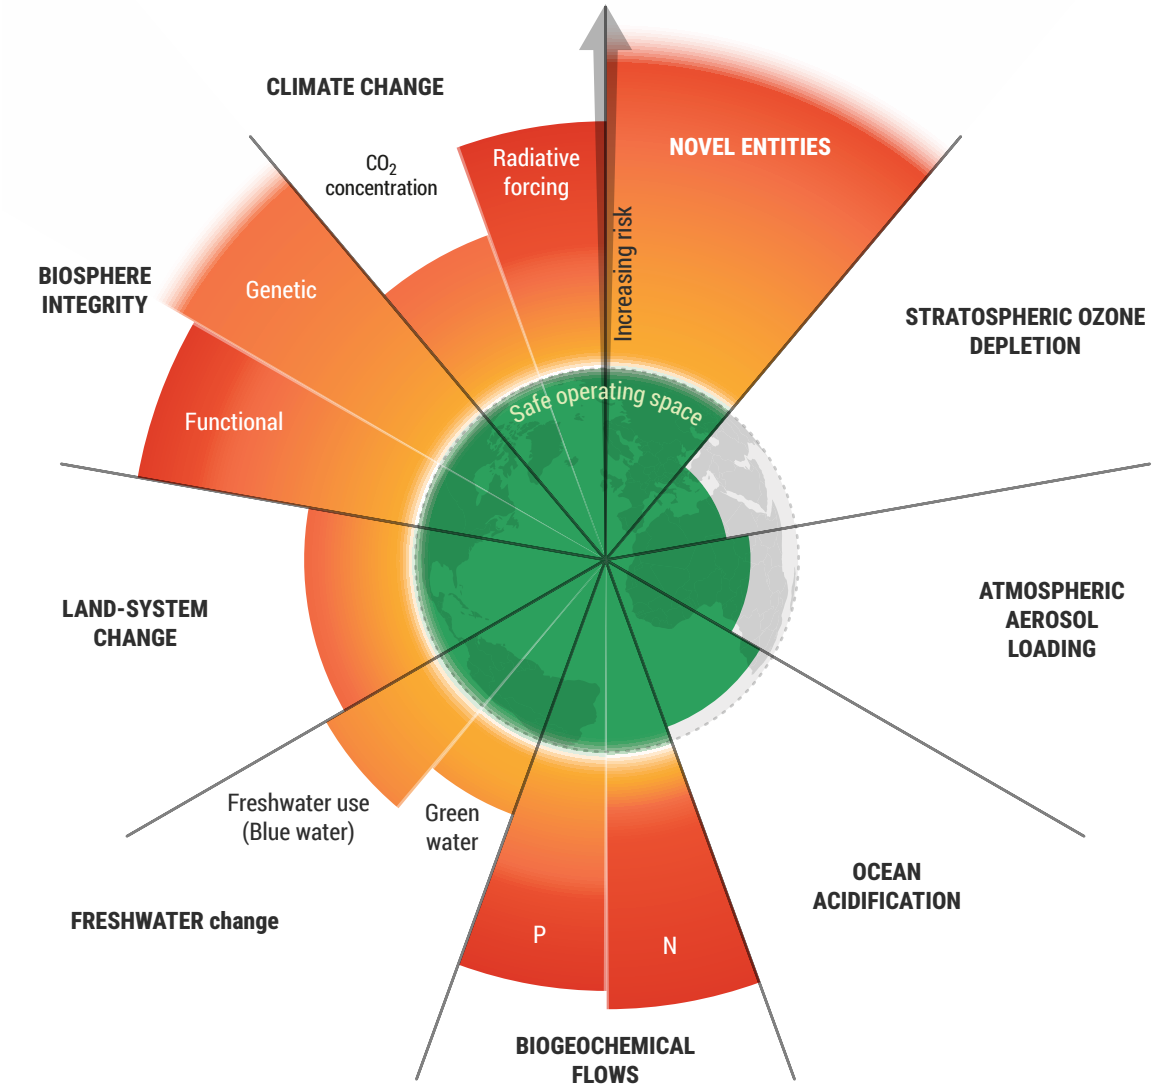
The global environmental crises reflect a complex interaction of unsustainable relationships between humans and nature, where several planetary boundaries are now surpassed beyond the safe operating space for humanity (Steffen et al. 2015; Richardson et al. 2023) (**Figure 18.1**). Representing a "global tragedy of the commons" that demands global collective action at all levels, these crises undermine humanity's ability to live in harmony with nature to achieve long-lasting sustainability (Ostrom 2010). However, individuals, communities, and governments lack adequate tools, approaches, incentives and motivation to act within current social, political and economic systems and priorities.

Global efforts through agreements, assessments, and initiatives reflect a broad consensus on the need for transformative changes in key human systems to tackle global environmental crises and GEO-7, Chapter 11 provides evidence that these transformations can achieve targets and goals, despite these being missed over the last two decades. Concerns from current trends and business as usual scenarios (Chapter 10) suggest that policy implementations to reduce GHG emissions will impede the achievement of the Paris Agreement's goals by 2030 (Stechemesser et al. 2024).

All major global initiatives – including the Sustainable Development Agenda 2030 and Sustainable Development Goals (SDGs), the 2022 Kunming-Montreal Global Biodiversity Framework (KMGBF), the Paris Agreement, the Land Degradation Neutrality goal under the United Nations Conventions to Combat Desertification, the United Nations Decade of Ecosystem Restoration, and the Early Warnings for All – clearly outline what actions are necessary. They emphasize the importance of transformative change across key human systems like energy, food, material resource circulation, and the economy. However, their implementation encounters obstacles and legacy challenges, such as resource shortages, policy inconsistencies, limited political commitment, weak enforcement, and gaps in local capacity, particularly in lower-income regions, where mainstreaming at the local level is often lacking.

These failures stem from multiple factors, including weak leverage points (Abson et al. 2017), insufficient monitoring of their application, limited collaboration between researchers and other stakeholders (Norström et al. 2020), neglect of social-ecological systems (Fischer et al. 2021), and inadequate transnational coordination and engagement (Folke et al. 2019). Driving transformational change across critical human systems while safeguarding the environment is both the most significant challenge and the greatest opportunity of these times.

There is strong evidence from legal, social, governance, and ecological viewpoints that a system-wide transformation is urgently needed (Atmadja et al. 2021; IPBES 2019; UN 2019; FAO 2021; UN 2023; IPCC 2023; Gupta et al. 2023). However, as emphasized in Chapters 11 and 12, many existing conceptual models primarily explore why transformation is essential, what it might look like and what could happen as a result.



However, there is limited understanding of how to make this transformation happen or how to distinguish between incremental changes and deep, systemic transformation.

To help fill this knowledge gap, this chapter, and the GEO-7 report as a whole, aims to illustrate solution pathways and their implementation using two target seeking scenarios that enable a more resilient and sustainable environment. This objective requires fostering transformation across the human-controlled energy, food, financial, and circularity systems for a future in which global targets for climate and biodiversity are met. Real-life examples and case studies are presented in this Chapter offering lessons that can serve as seeds for broader systems change.

One specific planetary boundary, the stratospheric ozone hole, was once an environmental issue but has been largely addressed – except for some recent anomalies in the southern hemisphere (European Environment Agency 2024).

This success is mainly due to the effective implementation of the Montreal Protocol (United Nations Environment Programme 1987), which is the only United Nations treaty ratified by every country and is known as a landmark achievement in scientific cooperation (Whitesides 2020). The treaty's effectiveness was supported by several factors. These include a relatively short period – a decade – during which scientific consensus was accepted, the availability of technological solutions, the straightforward nature of the problem since the

Figure 18.1: Current status of control variables for all nine planetary boundaries

Source: Azote for Stockholm Resilience Center, based on analysis in Richardson et al. (2023). Licensed under CC-BY-NC-ND 3.0

ozone hole was observed and measured, and strong collaboration between industry and policy.

This positive example does not represent the current complexities of global environmental crises but instead emphasizes the need for coordinated, multi-actor strategies, where strong levers are effectively integrated and applied. In GEO-7, earlier chapters present methods and solutions for transforming four key human-controlled systems: economy, circularity, energy, and food. Building on these insights, this chapter develops a narrative to create a sustainable and resilient environment system, outlining clear goals and the solutions needed to address the challenges of global crises. These goals are reached through a series of solutions narratives, which involve specific actions carried out across different time frames, scales, and by various actors. The chapter discusses various combinations of levers to overcome identified barriers and challenges in the transformation process. It aims to motivate key actors to implement solutions sustainably. The focus is on achieving the necessary scale and speed of transformation (Chapter 21), since there are numerous feasible solutions with strong scientific, technical, financial, and social potential already exist.

The chapter uses the concepts of socioecological systems (SES), which are self-sustaining and adaptable, including both nature and humans, and sociotechnical

Table 18.1: Goals to enable sustainable and resilient environment system for nature, circularity, energy and food

Goal
Ensure and Strengthening the Nature-Society-Economics Nexus
Enable Transformative Adaptation of Socioecological Systems for Climate Resilience and Deliver Enhanced Benefits to Nature and People
Restore Natural Capital through Circular Economy Strategies and an emerging Sustainable Bioeconomy

systems (STS), as fundamental units for change. SES and STS here are not limited to natural ecosystems but also encompass human-made systems such as urban and agricultural environments. SES refers to a coupled natural-human system that is interconnected and interdependent in complex ways. SES highlights that human-designed systems, like economies, societies, and cultures, are embedded within, influenced by, and evolving alongside the biosphere across local to global levels (Folke et al. 2016). The goal of transformative SES is to establish a safe operating space capable of adapting and transforming amid adverse drivers and pressures. This requires transformative changes in SES governance and resource use patterns to foster climate-resilient and biodiversity-caring development pathways (IPCC 2022). Such transformations should be safe, just for all, and aligned with the no-one-left-behind principle of the 2030 Sustainable Development Agenda. Simultaneously, science, technology, and service are essential for rapid shifts away from a fossil fuel-based economy and for modifying how society interacts with technology (Muscat et al. 2021).

To achieve a sustainable and resilient environment system for nature and facilitate transformation across four other systems, it is vital to adopt an integrated approach that aligns human activities with natural processes. This requires implementing transformative changes in economic, social, technological, and governance structures to address the global environmental crises (Rockström et al. 2009; Steffen et al. 2015). A sustainable circular economy, supported by suitable bioeconomy infrastructure, must be developed to reduce waste and optimize resource uses (Geissdoerfer et al. 2017; International Renewable Energy Agency [IRENA] 2020).

Similarly, food systems must adopt sustainable and regenerative practices that enhance biodiversity while securing food security, use new agri-technologies alongside preserving Indigenous and local farming methods, cut GHG emissions, and improve soil health (FAO 2018; IPCC 2019). Tackling the trade-offs between food and nature, while ensuring economic benefits for farmers, is recognized as significant and calls for systemic change as discussed in Chapter 17 on Food Systems. The use of SES and STS frameworks is important, recognizing the interconnectedness of human and natural systems, along with the potential of new technology and building resilience through adaptive governance, fair policies, innovation, and collaborative efforts (Ostrom 2009; Folke et al. 2016). Transformational strategies will also differ across regions and over time – as regional differences must be considered based on social, economic, technical, and natural features and limitations.

Three goals are proposed to enable a sustainable and resilient environment system that address how to support transformations across Circularity (Chapter 15), Energy (Chapter 16), and Food Systems (Chapter 17). These goals, presented in Table 18.1, are closely connected to the economic system and financial mechanisms outlined in Chapter 14.

18.1.1 Ensure and strengthening the nature-society-economics nexus

This goal emphasizes One Health approach that links ecological health with social and economic well-being to enhance the health of people, animals, plants, and ecosystems. It acknowledges that sustainable development depends on the harmonious coexistence of natural ecosystems, human societies, and economic activities (Rockström et al. 2009; Folke et al. 2016). By highlighting their interdependence, the goal seeks to encourage policies and practices that advance environmental sustainability, social equity, and economic resilience. (Ostrom 2009; Steffen et al. 2015). Implementing sustainable land use involves conserving natural habitats, promoting regenerative agriculture (Chapter 17), and preventing deforestation. These actions protect biodiversity and boost ecosystem services like water purification and carbon sequestration (Altieri, Nicholls, and Montalba 2017; Pretty et al. 2018). Using green infrastructure in urban areas, such as green roofs, permeable pavements, and urban forests, can lower urban heat islands, reduce flood risks, and improve air

quality, benefiting public health (Gill et al. 2007; Tzoulas et al. 2007). Supporting sustainable consumption and production patterns includes adopting renewable energy, minimizing waste through prevention, recycling, and composting, and supporting local, sustainable products. (Geissdoerfer et al. 2017; Kirchherr, Reike, and Hekkert 2017). These efforts help protect biodiversity, mitigate climate change, and ensure that economic growth does not compromise the well-being of people, animals, and the environment, while also promoting social equity and justice (Díaz et al. 2019). For instance, urban planning that integrates green spaces and promotes biodiversity can improve air quality, boost residents' well-being, and create economic opportunities through ecotourism and sustainable businesses (Elmqvist et al. 2013; Wu 2014). Strengthening these positive connections enables societies to develop more resilient and fair communities that operate within the planet's ecological boundaries (Steffen et al. 2015; Folke et al. 2016).

18.1.2 Enable transformative adaptation of socioecological systems for climate resilience and delivering enhanced benefits to nature and people

The goal is to develop the adaptive capacity and resilience of various types of SES across regions, while also providing greater benefits to nature and people over time. Moving beyond incremental adaptation, it emphasizes transformative adaptation achieved through strategic, spatially targeted planning, along with effective monitoring, reporting, and evaluation to tackle severe climate impacts. It also highlights the importance of avoiding unintended consequences, when necessary, by fundamentally alteration of certain attributes of SES. When systematically designed and implemented, planned transformative adaptation can be accelerated by solutions that are locally appropriate, based on Indigenous Knowledge and Local Knowledge. This approach integrates disaster risk reduction (DRR) so communities can better anticipate and prepare for, and respond to climate impacts, such as from forest fires or to the energy systems, thereby minimizing damages to ecosystem, human health, and property, and loss of life (Berkes 2007; Lavell et al. 2012). Utilizing Indigenous Knowledge and Local Knowledge enhances climate change adaptation (CCA) effectiveness by incorporating proven practices rooted in local ecosystems (Berkes, Colding, and Folke 2000; Hill et al. 2020), while also avoiding maladaptation. Since CCA often requires responses tailored to specific contexts, the focus is on initiatives that strengthen local resilience, such as establishing community-based adaptation (CBA) or community-based DRR groups. These efforts can promote collective action and empower communities to manage their CCA processes (Ostrom 1990; Agrawal 2001). Transformative adaptation goes beyond merely enhancing livelihood resilience or helping vulnerable groups cope with and recover from climate shocks. It also involves protecting ecosystems and biodiversity, preventing land degradation, and supporting climate mitigation, such as through deployment of agrivoltaics or solar panels (Chapter 16) (Adger 2006; Cutter et al. 2008). It offers co-benefits like better water quality, higher biodiversity, and improved livelihoods for local communities, aligned to the target seeking scenarios of GEO-7 (The Economics of Ecosystems and Biodiversity [TEEB] 2010; Barbier et al. 2011). Moreover, incorporating CCA into urban planning, energy systems, forest management, agriculture, and water management can foster more resilient and sustainable systems that enhance human well-being and ecological health (IPCC 2014; UNEP 2019).

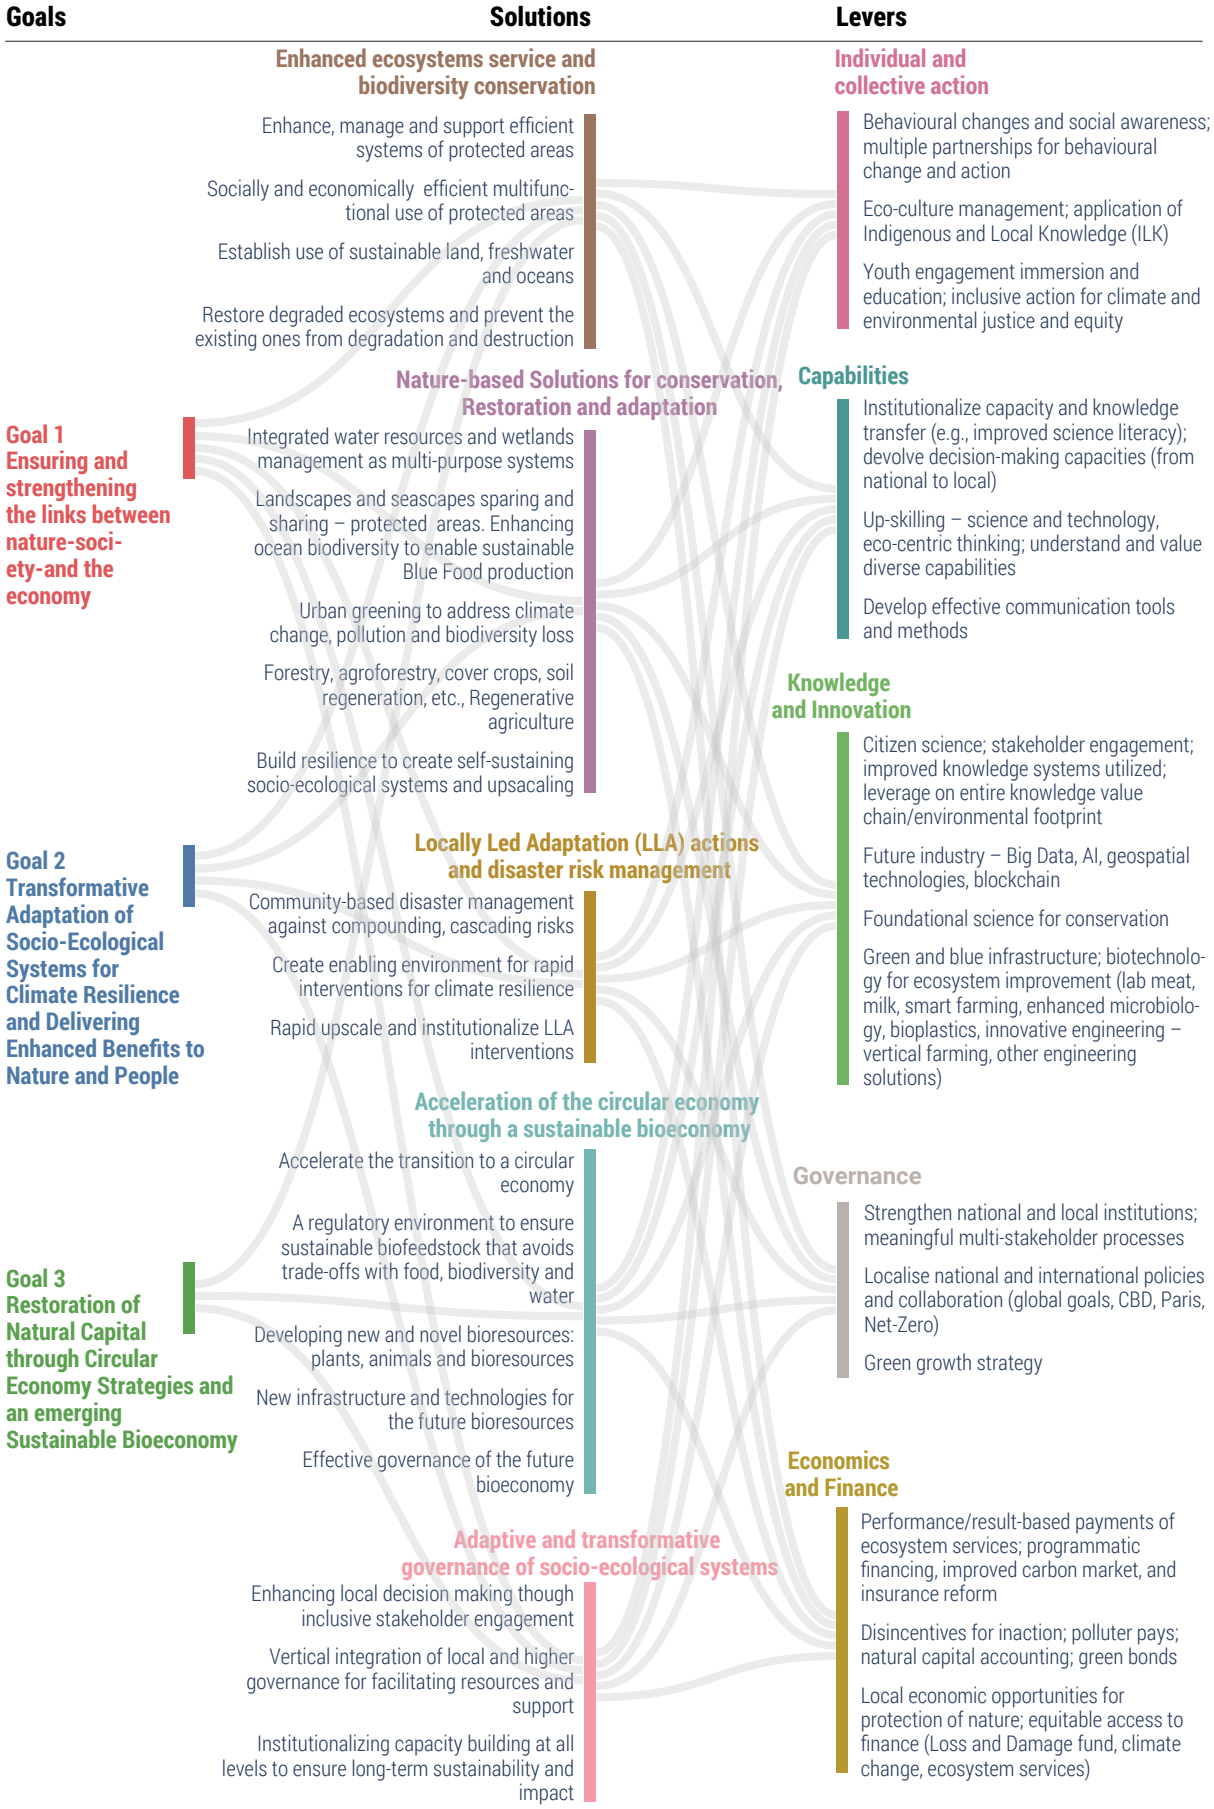
18.1.3 Restore natural capital through circular economy strategies and a sustainable bioeconomy

The goal aims to decrease resource depletion and environmental harm by shifting to sustainable consumption and production systems (Chapter 15). By tilizing biological resources for various applications (IEA 2022), a sustainable bioeconomy employs renewable biological materials to generate energy, food, chemicals, and other products in a sustainable way. This approach helps cut fossil fuel dependence, lowers greenhouse gas emissions, stores carbon, and reduces economic stress on ecosystems and biodiversity (Bugge, Hansen, and Klitkou 2016; Kirchherr, Reike, and Hekkert 2017). Numerous examples and case studies demonstrate the advantages of utilizing biological resources for multiple purposes and is aligned to the GEO-7 target seeking scenarios, where biomass, including from waste streams, is critical in both Behaviour- and Technology-focused Scenarios to meet climate targets for 2050. A comprehensive life cycle assessment of biorefineries is essential to confirm that these methods have lower environmental impact than fossil fuels, despite considerable variations. Overall, studies show that biorefineries show clear environmental benefits (Munagala et al. 2021; Lindorfer, Zeilerbauer, and Hrbek

2022). These facilities convert biomass into valuable products, such as biofuels and bioplastics, reducing the environmental impact of production processes (Cherubini 2010). Promoting sustainable agricultural practices, that enhance soil health and biodiversity (Chapter 17) such as agroforestry, crop rotation, and organic farming, can boost yields, strengthen resilience to climate change, and decrease reliance on synthetic fertilizers and pesticides (Altieri, Nicholls, and Montalba 2017; Pretty et al. 2018). Developing markets for biobased products involves researching, developing, and commercializing innovations such as biodegradable packaging, biobased textiles, and biofuels (Carus and Dammer 2018). Combining these strategies aims to regenerate natural capital, improve ecosystem services, and foster economic growth that is environmentally sustainable and socially inclusive (El-Chichakli et al. 2016). For instance, utilizing agricultural waste to produce bioenergy or sustainable aviation fuels offers a renewable energy source, reduces pollution, and boosts economic opportunities in rural areas (Scarlat et al. 2015). Additionally, shifting to a circular economy can foster new technologies and innovations, open up new business prospects, and promote economic growth while conserving natural resources and restoring ecosystems (Chapter 15) (Geissdoerfer et al. 2017).

18.2 Solution pathways for a resilient and sustainable environment system

Five integrated solution pathways have been identified to achieve the three overarching goals (**Figure 18.2**).



First, biodiversity protection, conservation and restoration can be advanced by enhancing ecosystem services (**Box 18.1**) through multiple approaches. Expanding and connecting protected areas, along with establishing biodiversity buffers and corridors, allows species to migrate, adapt, and thrive in changing environments. This helps to maintain ecosystem integrity, safeguarding natural ecosystems while providing co-benefits such as improved water quality, increased biodiversity, improved soil and air quality, and enhanced livelihoods.

Second, wide scale implementation of NbS can simultaneously achieve conservation, restoration, GHG mitigation, DRR, and CCA. NbS, such as reforestation, wetland restoration, urban greening, and sustainable agriculture, offer multiple benefits including habitat protection, climate mitigation, carbon sequestration, energy savings and improved water quality. Regenerative production systems like agroecology and permaculture

Figure 18.2: The Goals and Solution Pathways, with key levers identified to enable a sustainable and resilient environment system for nature, finance, waste/circularity, energy and food

Box 18.1: Biodiversity conservation and enhanced ecosystem services

Biodiversity, encompassing ecosystem, species, and genetic diversity (International Fund for Agricultural Development 2024), is essential for the provision of ecosystem services (Reid et al. 2005). According to the Millenium Ecosystem Assessment, ecosystem services are the benefits people obtain from ecosystems. These include provisioning, regulating, cultural and supporting service. The type and magnitude of the ecosystem services is directly influenced by the level of biodiversity. Certain ecosystems, like tropical rainforests, mangroves, wetlands, and coral reefs, are particularly effective in providing regulating and supporting services such as carbon sequestration and water purification, although they may offer less provisioning or cultural services. Therefore, biodiversity of an ecosystem largely determines the range and quality of services it can provide to people.

Specifically, species diversity plays a critical role in ecosystem functioning and service delivery capacity, shaped by species interactions and environmental conditions. It supports natural pest control and pollination, and agricultural productivity, and ensures the availability of essential materials (FAO 2022). Genetic diversity is equally important. It enhances ecosystem resilience, supports self- regulation, and improves the ability of ecosystems to adapt to environmental changes. In turn, this is what determines the long-term provision of ecosystem services for human well-being (Hoban et al. 2021).

restore soil health, boost biodiversity, and strengthen ecosystem resilience.

Third, CCA strategies can be improved by implementing integrative methods to strengthen SES resilience through scaling up LLA, combined with effective DRR. LLA efforts draw on Indigenous Knowledge and Local Knowledge to develop context-specific solutions that enhance community resilience.

Fourth, accelerating the development of a biobased circular economy shifts from the traditional linear model of "take, make, dispose" to one that minimizes waste and limits the extraction of new resources. Sustainable bioresources provide environmentally friendly alternatives to fossil fuel-based products. Building the bioeconomy infrastructure, such as biorefineries and supply chains for biobased products, enhances resource management, cuts waste, and encourages the use of renewable biological materials. These efforts support the creation of a resilient and sustainable economy.

Fifth, the solution is adaptive and transformative governance that connects local communities, enhances society's environmental awareness, and fosters a better attitude towards nature. It aims to transform people's consumption behaviours and habits while integrating Indigenous Knowledge and Local Knowledge. This solution involves moving governance towards collaborative networked structures, where decision-making takes place at various scales and a higher degree of power is given to communities. This approach ensures their knowledge and needs are incorporated into broader policy frameworks (Folke et al. 2005; Armitage, Berkes, and Doubleday 2007).

18.2.1 Enhancing ecosystem services through regenerative systems and biodiversity conservation

We define four consecutive actions to strengthen ecosystem services through regenerative systems and biodiversity conservation, aiming to achieve Environmental Goals.

18.2.1.1 Action One: Enhance, manage and support an effective networks of protected areas

Creating protected areas, as identified in the GBF 30 x 30 target 3, doesn't automatically result in better ecosystem health or increased biodiversity conservation. Protected areas, regardless of size, must be interconnected, preserved, and effectively managed (Geldmann et al. 2018). Both target seeking scenarios of GEO-7 envision pathways to increase protected areas, ranging from 30 per cent to 50 per cent. Several nations demonstrate strong potential for successful management of protected areas (Watson et al. 2014). Australia has met its international goals by achieving 17 per cent of its land designated

as protected, fulfilling Aichi Target 11. Meanwhile, South Africa and Canada have significantly expanded their protected area networks since 2010. At both national and regional levels, there is a need for in situ conservation approaches – protecting species in their natural habitat – is needed at both regional and national levels. This includes establishing and maintaining natural parks, wildlife sanctuaries, marine protected areas, and biosphere reserves, ideally through regional collaboration with neighbouring countries.

Protection status should be extended not only to threatened, representative, or rare ecosystems but to all ecosystem types that provide essential services (Coad et al. 2019). Some habitats, like coastal areas, are more vulnerable than others (Mammides et al. 2024). The size of protected areas may vary based on economic, social, and natural factors, but they should form a continuous network. This includes incorporating corridors and service-rich areas to allow the flow of species, nutrients and energy between different ecosystems or their parts. While creating a single global network of protected ecosystems may be unrealistic, a regional level is feasible. Examples of success include the international Emerald Network and Natura 2000 projects in Europe, the Ecological Conservation Redline national programme in China, the Yellowstone to Yukon Conservation Initiative that aims to create a continuous wildlife corridor spanning over 3,200 km and connects Yellowstone National Park in the US to the Yukon in Canada, and on a local level in cities by organizing a multifunctional and interconnected green infrastructure, such as in Canberra and Minsk (Hilty and Laur 2021).

Depending on an area's fragility or exposure, different kinds of economic activities may be permitted, like IUCN categories imply, to make conservation areas economically viable for local populations and governments. Legal instruments, such as Chile's Real Right of Conservation, which allows landowners to protect their land indefinitely while pursuing economic activities. These frameworks serve as the cornerstone for conservation initiatives, encouraging the preservation and flourishing of ecosystems (Government of Chile 2016). Spatial tools and technologies, such as GIS, sensors, drones and satellites provide real-time information about ecosystems health and patterns of biodiversity. This is particularly valuable for managing biodiversity corridors, by tracking species movement and monitoring habitat conditions (Soubry et al. 2021).

Developing locally appropriate infrastructure is crucial for making protected areas economically viable. Low-impact roads, visitor centres, and energy-efficient lodges can foster ecotourism and other economic activities. For example, Norway's Jotunheimen National Park introduced eco-friendly infrastructure without causing harm to the delicate alpine ecosystem (Visit Norway 2024). In Costa Rica, the Ministry of Environment and Energy implements a National Policy for Production and Sustainable Consumption (2018–2030), which integrates sustainability into tourism. This policy helps to reduce habitat destruction, resource overuse, and pollution caused by the industry, while promoting economic resilience by fostering local entrepreneurship and creating green jobs.

Conflicts of interest, such as mining, urbanization, forestry or fishing, can generate larger short-term profits than conservation should be addressed through conflict resolution and co-management strategies. Participatory land-use planning, like practiced in Madidi National Park (Bolivia), involves stakeholders in mapping resource use and designating areas for conservation and development. Benefit-sharing models, such as revenue-sharing with Maasai communities around Amboseli National Park (Kenya), encourage conservation by linking park income to local education and health care. Employing residents as rangers or guides in these areas also offers economic opportunities linked to conservation (Bauer et al. 2022).

Biodiversity hotspots in Bolivia, Brazil, Colombia, and Congo are increasingly impacted by urban sprawl, making conservation near large cities challenging and often leading to human-wildlife conflicts (Molotoks et al. 2017). In Brazil, Brasília National Park, which surrounds the city of Brasília, has been affected by rapid urban expansion (Diniz and Vieira 2016). Similarly, urban sprawl in Nairobi has degraded Nairobi National Park by shrinking wildlife corridors, increasing human-wildlife conflicts, and raising the levels of pollution from point sources (Onkangi et al. 2023).

In some areas, conservation has been shown to economically benefit only a few elite leaders and investors, rather than most community members who forgo advantages from non-conservation land uses when protected areas are established (Sene 2024).

To overcome such barriers, conservation laws or rights established in some countries have proven to be effective tools, such as in the case of Chile, the Real Right of

Conservation involves a binding agreement between the property owner and a third party, whereby the landowner permanently restricts the development and future use of their land to ensure its protection and conservation. In turn, the third party, which may be a university, research centre, non-governmental organization (NGO) or individual, commits to protecting and conserving the natural resources of the property.

18.2.1.2 Action Two: Offer a socially and economically efficient multifunctional use of protected area by leveraging the resources approach

It is essential to account for the cultural and provisional services of protected areas to enhance their appeal and utility for local governments and communities, including women and marginalized groups, who often perceive protected areas as mere lands that are unprofitably withdrawn from development (United Nations Educational Scientific and Cultural Organization 1971). The following examples offer opportunities to ensure success:

- Acknowledging that expanding protected areas involves many of the poorest rural regions in the world, Green Colonialism and land grabs for conservation should be avoided. Global justice, such as fair sharing of costs, benefits, and responsibilities should be a future high priority (Ma et al. 2020).

- Fostering sustainable ecotourism, which connects visitors to the protected areas while contributing to the income of local communities and ecosystem conservation should be prioritized. Eco-lodges, guided wildlife excursions, and educational programmes provide a means to attract visitors without causing harm to the ecosystem, such as in Costa Rica's Monteverde Cloud Forest, where eco-tourism is providing local employment opportunities, with revenue reinvested in preserving the forest, making eco-tourism a powerful instrument for both economic development and conservation (Miller, Cox, and Morse 2023).

- Collaborative management approaches, where communities actively engage in the administration of protected areas, cultivate a sense of ownership and responsibility for conservation efforts and create jobs. In Kenya, community-based conservation initiatives engage residents in management of protected lands and offer economic opportunities through ecotourism and sustainable farming. Similarly, in Türkiye's Gökova marine protected area local fishers are trained and employed as marine rangers to stop illegal fishers from other regions (Ünal and Kizilkaya 2019). This approach has led to a significant recovery of fish stocks and increases in the apex predator biomass with higher incomes for local communities (Vasconcellos and Unal 2022).

- Agroforestry practices can help communities near protected areas to earn income while conserving biodiversity through sustainable harvesting of non-timber forest products and food. In Kenya, many protected areas allow local people to manage livestock grazing in a way that balances conservation and livelihood needs (Bedelian and Ogutu 2017).

- Using protected areas as platforms for scientific exploration and education, such as in Ecuador's Yasuni National Park (Bass et al. 2010).

18.2.1.3 Action Three: Establish a sustainable use of land, fresh water and oceans

Biodiversity conservation can be established not only in protected areas, which currently cover about 16.44 per cent of land and fresh water and 8 per cent of oceans (OECM 2022), but also in areas used for other economic activities. These areas can directly support Target 10 of the GBF on sustainable management of these sectors. Such practices also contribute to achieving other KM-GBF goals, including Target 1 on sustainable management and Target 7 on pollution reduction and is relevant to sustainable practices for agriculture, fishing and forestry, sustainable urban development and fossil fuels and actions one and two greatly contribute towards this third action.

Sustainable agriculture can help prevent biodiversity loss by reducing the use of pesticides and fertilizers, and more efficient use of arable lands and water through regenerative practices (Chapter 17). In Sub-Saharan countries, regenerative agroecological practices, such as minimizing soil disturbance, using legume crops to boost nitrogen levels and suppress weeds, and diversifying crops, have improved soil health and stabilized yields even in stressful climates (Nyirenda and Balaka 2021).

Sustainable forestry is currently the sector which has the most well-studied practices to conserve forest ecosystems and their biodiversity. It includes delivering collateral-free microfinance to small forest-based businesses through the power of collective organizations, applying new diagnostic tools and methodologies to catalyse legal-reform processes for sustainable wildlife management, harnessing digital technologies to improve the efficiency of timber-tracking and promote sustainable supply chains, all aimed at increasing sustainable forest management. Programs like Sembrando Vida in Mexico promote agroforestry and silvopasture systems to restore ecosystems. These systems use such practices as no-till farming, cover crops, and crop rotations to regenerate depleted pastures (Altieri and Nicholls 2012).

Managing pollution requires reducing the duration, amount, and pattern of pollutant exposure to protect vulnerable ecosystems from pollutants like plastics and microplastics in freshwater and marine environments (UNEP 2023). Establishing marine conservation zones and promoting responsible fishing are essential for maintaining marine biodiversity and avoiding overfishing. In New Zealand, a network of marine protected areas conserves key habitats, while the Quota Management System enforces strict fishing limits to keep fish populations sustainable (Mossop 2020).

Urban biodiversity presents another challenge because habitats in cities are often limited and unsuitable for many species. The sponge-city models in China, which incorporate urban wetlands, public gardens, and renaturalized river valleys, help boost urban biodiversity by creating additional habitats (Ronchi and Salata 2022).

Since all natural resources are interconnected, management plans need to reflect these relationships. For instance, Integrated Coastal Zone Management programmes, like those in the Mediterranean, adopt a comprehensive approach by coordinating policies across various sectors such as agriculture, fisheries, tourism, and urban development. This helps ensure that land-based activities do not harm freshwater and marine ecosystems, promoting a sustainable balance between development and environmental protection (Ramieri, Bocci and Markovic 2019).

Marine Spatial Planning is another example of a decision-making approach that integrates managed and protected zones to enhance resilience in natural resource management. Establishing legal frameworks and policies for resource use is vital for regulating land, water, and ocean activities. For example, the European Union's Common Fisheries Policy sets fishing quotas to prevent overfishing and allow marine ecosystems to recover. Similarly, Brazil's Forest Code ensures land-use practices do not lead to deforestation or harm freshwater systems. These legal structures help prevent overexploitation and promote sustainable practices across agriculture, forestry, and fisheries (Frost and Andersen 2006).

To ensure sustainability initiatives are truly rooted in local contexts, promoting community-led resource management is essential. In the Pacific Islands, community-based fisheries management merges traditional knowledge with modern conservation methods, helping to preserve fish stocks for future generations while supporting local economies (Lalavanua, Govan, and Steenbergen 2021).

Market-based tools and financial mechanisms, such as payments for ecosystem services (PES), carbon credits, and certification schemes, serve as effective incentives for sustainable practices, as detailed in Chapter 14. For example, in Costa Rica, the PES programme rewards landowners for conserving forests that benefit fresh water and biodiversity. To improve PES outcomes, it is crucial to broaden its scope beyond just compensation by incorporating capacity-building initiatives and educational programmes. This approach equips landowners with the technical skills and resources needed for sustained, active participation in sustainable practices. Certifications like the Forest Stewardship Council and the Marine Stewardship Council for fisheries recognize companies that demonstrate responsible ecosystem management and have been effective.

To ensure the success of sustainability efforts, building solid partnerships among governments, NGOs, private companies, and local communities is crucial. An example is The Amazon Cooperation Treaty Organization serves as a prime illustration of cross-border collaboration in managing the Amazon rainforest's vast biodiversity. In Norway, public education initiatives around sustainable seafood have increased consumer demand for sustainably certified fish, strengthening market-driven conservation.

18.2.1.4 Action Four: Restore degraded ecosystems and prevent the existing ones from degradation and destruction

Restoring degraded ecosystems is challenging, long-term, and expensive. Ecosystem restoration encompasses

a wide range of actions designed to repair damaged, degraded, or destroyed ecological systems, thereby restoring their biological and physical integrity (Aronson et al., 2020). It also includes conserving ecosystems that remain undamaged (UNEP and FAO 2020). The primary goal of ecosystem restoration is to accelerate recovery after damage or degradation, guiding ecosystems back towards their natural development path rather than their exact historical state (Balaguer et al. 2014). The GBF and UN Decade on Ecosystem Restoration (2021-2030) calls for global efforts to protect and revive ecosystems for the benefit of both people and nature. Initiatives like the Bonn Challenge and Latin America's 20x20 have already restored millions of hectares of degraded land, supporting food security and climate change mitigation.

Wetland restoration remains vital for enhancing biodiversity, maintaining freshwater supplies, and preventing floods. The Florida Everglades restoration (US Army Corps of Engineers 2020) demonstrates efforts to counteract the effects of urban development and intensive farming. Coastal ecosystems, including mangroves, coral reefs, and seagrass beds, function as natural shoreline protectors, support marine fisheries, and help absorb carbon. In Bangladesh, coastal mangrove restoration initiatives have protected communities from flooding and storm surges, while offering habitats for fisheries (United Nations Development Programme 2021). Similarly, restoring coral reefs and seagrass meadows has been vital for conserving marine biodiversity. In Australia, the Great Barrier Reef is safeguarded through coral restoration efforts that employ advanced methods, including robotic technology to plant coral fragments (Great Barrier Reef Foundation 2023).

To avoid further deterioration and destruction of ecosystems, it is crucial to adopt measures for pollution control and cleaner industrial practices aligned with circular economy principles, along with effective waste management systems to reduce industrial effluent and chemical waste. Germany's Circular Economy Act encourages businesses to focus on waste prevention, reuse, and recycling, leading to a significant decrease in landfill waste and enhanced resource efficiency (Federal Ministry for the Environment Climate Action, Nature Conservation and Nuclear Safety 2012). Likewise, implementing cleaner production techniques in Bangladesh's textile industry, supported by initiatives such as the Partnership for Cleaner Textiles, has resulted in notable reductions in water and chemical consumption, improved worker safety, and decreased environmental pollution in rivers (International Finance Corporation, 2017). In China's Yangtze River Basin, pollution control efforts have effectively decreased factory-related water pollution, safeguarding aquatic life and improving water quality for millions. Involving local communities in ecosystem restoration and conservation is essential. Empowering these communities encourages sustainable stewardship and reinforces social and cultural connections to the environment. Namibia's Community-Based Natural Resource Management programmes, which grant local communities rights over natural resources, have led to reductions in poaching, growth of wildlife populations, and improved livelihoods (Ministry of Environment Forestry and Tourism and Namibian Association of CBNRM Support Organizations 2021). Similarly, in Nepal's Annapurna Conservation Area, community forestry has enhanced forest cover, biodiversity, and water resources while providing communities with forest products (Baral and Heinen 2020).

Revitalizing soil health is essential for ecosystem restoration. Methods for soil restoration, such as planting cover crops, rotating crops, using crop waste for compost improve soil fertility, decrease erosion, boost carbon storage, and remediate polluted soils.

A key part of any nature restoration strategy is developing regulatory and legal frameworks that enforce ecosystem restoration and penalize degradation. Governments need to establish strong regulations that require companies in sectors like agriculture, resource extraction, construction, and industry to adopt sustainable practices. For instance, Brazil's Forest Code requires landowners to restore forests in designated areas like riverbanks and enforces penalties for non-compliance. Applying similar regulations to other sectors would make environmental restoration a legal requirement rather than a voluntary effort, compelling companies to incorporate restoration into their operations. Additionally, the EU's Nature Restoration Law aims to restore at least 20 per cent of the EU's land and sea areas by 2030 and all ecosystems needing restoration by 2050.

Environmental permits and conditional licences should be connected to commitments for restoring ecosystems. By mandating companies to provide financial guarantees like environmental bonds, it can be ensured that funds are available for future restoration efforts, holding companies accountable for their environmental responsibilities. For instance, in Australia, mining companies are legally obliged to supply financial bonds to cover the costs of rehabilitating mine sites after operations end

(Government of Western Australia 2012). These bonds are only refunded once the rehabilitation satisfies specific environmental standards.

Public-private partnerships play a vital role in large-scale ecosystem restoration, where businesses, governments, and NGOs collaborate to rehabilitate degraded lands. Initiatives like the Bonn Challenge, a global effort to restore such lands, highlight the potential of collaboration. Governments can motivate companies to get involved through financial or tax benefits, fostering a positive cycle that encourages voluntary corporate engagement in restoration efforts.

18.2.2 Nature-based solutions for conservation, restoration and adaptation

Strategies for the widespread implementation of NbS to promote conservation, restoration, and CCA are key to increase environmental sustainability and resilience (**Figure 18.3, Box 18.2**).

18.2.2.1 Action One: Rapidly develop and implement nature-based solutions

The development of NbS is an adaptive and iterative process that can be achieved by following a series

Figure 18.3: Examples of nature based solutions for climate change adaptation

Air and water pollution

- Riparian buffer strips: Vegetated areas along waterways trap sediments and filter pollutants.
- Urban green belts: Trees absorb air pollutants and fine particulates.
- Wetland conservation: Filters industrial and agricultural runoff naturally.
- Algal ponds & constructed wetlands: Clean wastewater while supporting biodiversity
- Crop plants engineered to be more resource use efficient: plants that use phosphorous and nitrogen more efficiently, with less run-off into aquatic systems.

Flooding

- Riverbank reforestation: Roots stabilize banks and reduce erosion.
- Floodplain restoration: Allows rivers to safely overflow and recharge groundwater.
- Urban permeable surfaces: Green infrastructure such as permeable paving, rain gardens, and green roofs.
- Mangrove belts: Break storm surges and slow tidal flooding.

Vulnerable small-scale farmers

- Diversified cropping systems: Reduces risk from single crop failure.
- Community seed banks: Preserve climate-resilient local varieties.
- Agroecology training: Builds capacity to farm with fewer external inputs.
- Payments for ecosystem services: Farmers get income for conserving biodiversity or sequestering carbon.

Soil drought

- Agroforestry: Shade trees reduce evaporation and improve soil moisture.
- Mulching and cover crops: Maintain soil humidity and reduce temperature extremes.
- Terracing and contour farming: Slow runoff and allow more water to infiltrate soil.
- Wetland restoration: Retains groundwater and stabilizes the local water table.
- Resilient germplasm: germplasm able to tolerate lowered ground water and still producing yieldable crops.

Soil pollution by chemical fertilizer

- Organic soil amendments: Compost, manure, and biochar bind toxins and restore soil structure.
- Phytoremediation: Plants such as Viola baoshanensis can absorb and break down pollutants.
- Crop rotation with legumes: Fix nitrogen naturally, reducing need for synthetic fertilizers.
- Mycoremediation: Fungi break down harmful chemicals in soil.

Drought

- Watershed restoration: Reforestation to improve water infiltration and storage.
- Rainwater harvesting with vegetative catchments: Plants slow and store runoff for later use.
- Soil organic matter enrichment: Improves water retention capacity.
- Mangrove and wetland protection: Maintain regional humidity and rainfall cycles.

Fossil fuel-based energy system

- Bioenergy from waste and sustainable cropping: Agricultural residues, manure, forest and grass non-food cropping and by-products for renewable energy.
- Agroforestry for biomass: Sustainable wood and bamboo production.
- Passive cooling and heating: Green roofs, living walls, and urban tree cover to reduce energy demand.

Box 18.2: Features of nature-based solutions

Nature-based solution (NbS) are actions that protect, conserve, restore, sustainably manage natural or modified terrestrial, freshwater, coastal, and marine ecosystems. They aim to address social, economic, and environmental challenges in an effective and adaptive way, while also providing benefits for human well-being, ecosystem services, resilience and biodiversity (UNEP 2022).

- **Societal focus:** Unlike traditional conservation, restoration and adaptation that primarily focus on nature, NbS begin with societal needs and use nature to deliver sustainable outcomes.

- **Guiding principles**: The design and implementation of NbS should follow eight principles of the IUCN Global Standard (International Union for Conservation of Nature 2020), ensuring that solutions are scalable, contribute to biodiversity and ecosystem integrity, economically viable, equitably balance trade-offs, based on inclusive governance, and adaptively managed using evidence for long-term sustainability.

- **Applications**: NbS are applied in conservation, restoration and adaptation of ecosystems to deliver enhanced benefits for nature and people.

- **Benefits**: NbS support the development of sustainable and resilient environment system and can drive broader systems transformation (Kinol, Arango-Quiroga, and Kuhl 2023). NbS are cost-effective (Lafortezza et al. 2018), multifunctional and adaptable across different sectors (Engström et al. 2018). NbS also offer co-benefits, such as nature conservation as well as improved human livelihoods and well-being (Dhyani et al. 2020). Additionally, many Indigenous Knowledge and Local Knowledge systems are inherently nature based.

- **Justification for NbS**: According to Palomo et al. (2021), ten elements underpin successful NbS. These are: Nature's values, Knowledge types, Community engagement instruments, Economic and financial tools, Rights-based and customary norms, Legal and regulatory frameworks, Management practice, Strategic planning, Behavioural change, and Technology.

- **Types of NbS**: The Technical Handbook of NbS describes three main types of NbS categorized by function and the level of ecosystem intervention (Eisenberg et al. 2022).

    - Type 1: Minimal intervention
    - Type 2: Moderate intervention
    - Type 3: High intervention

NbS case examples: An example of Type 1 is the protection of mangroves in coastal areas, such as the Mangrove National Park in the desert landscape of Abu Dhabi in UAE, that help to limit climate risks and provide socioeconomic benefits and non-material ecosystem services. Agroecology and natural systems agriculture as demonstrated by the 5,500-member eco-village located in the semi-arid drylands of Chololo, the United Republic of Tanzania (Ramesh et al. 2015; IPBES 2019) is an example of a Type 2 NbS. An example of Type 3 NbS is engineered green and blue infrastructures in Bishan-Ang Mo Kio Park, Singapore.

of four subactions: defining the problem, planning, implementation, and monitoring and governance.

NbS begins by clearly defining the problem from a societal perspective. For instance, the success of the West Africa Coastal Areas Management Program can be attributed to its problem-solving approach, which uses NbS to address community needs and protect against natural and man-made risks such as coastal erosion and flooding (Ramesh et al. 2015). This influences the socioecological interactions of coastal communities. This people-centric approach to NbS aims to transform these communities by providing enhanced benefits to both nature and people.

In this context, knowledge assets held by various actors can clarify expectations and limitations of stakeholder involvement, helping to address barriers like mutual misunderstanding (Gardner 2021) and avoid deployment a one-size-fits-all solutions approach (Kabisch et al. 2016).

The second step in planning for NbS involves co-creation and development that includes several detailed steps: defining settings together, understanding challenges, creating visions and scenarios, assessing potential impacts, developing solution strategies, and implementing and monitoring initial actions (Albert et al. 2021; Brierley and Fryirs 2022). The Intercontinental Biosphere Reserve of the Mediterranean, spanning Andalusia (Spain) and Morocco (Barbosa et al. 2019), demonstrates that involving key stakeholders—including regional and local governments of Andalusia and the Kingdom of Morocco—in NbS planning helps identify the most effective network of multipurpose protected areas. The success of NbS is further supported when project mandates are approved by relevant and major stakeholders.

Research and practice show that successful implementation, the third subaction of NbS, is required to follow certain principles to ensure success —such as Place-specificity, Evidence base, Integration, Equity, and Trans-disciplinarity—and collaboration among key stakeholders from both public and private sectors (Kabisch, Frantzeskaki, and Hansen 2022). A community-managed NbS was used to address climate-related risks in the Duwa and Sutebwo forests of the Segou Region in Mali by restoring the dryland through regrowth (Hou-Jones, Roe, and Holland 2021). Since NbS tend to be linked to specific locations (Schröter et al. 2023), the principle of place-specificity was demonstrated in this farmer-managed natural regeneration approach. It was reported that 8,300 hectares of degraded forest land saw improvements in water retention and soil fertility (Hou-Jones, Roe, and Holland 2021). Additionally, 75 per cent of intervention beneficiaries reported having fairer and more equitable access to forest resources.

Implementing NbS faces several barriers, including lack of accessible funding and financial tools, that required innovations in financial systems as described in Chapter 14, resistance rooted in knowledge gaps, limited participation of local stakeholders, and poor coordination among sectors and actors (Sarabi et al. 2019, Dubo et al. 2023). Funding options for NbS range from purely public sources to public-private partnerships and blended finance, but research indicates the private sector could contribute more significantly to achieving transformative goals at scale. A 2022 report on NbS financing revealed that to meet climate, biodiversity, and land degradation targets through NbS, investments need to rise sharply to $384 billion annually by 2025, more than doubling the current $154 billion annual investment (UNEP 2022). The private sector has a crucial role in effectively implementing NbS, especially in developing and emerging economies by overcoming major financial, technical, and governance challenges. With a notable funding shortfall in NbS projects, private investments via blended finance, public-private partnerships, and impact-investment models can provide vital resources to expand NbS initiatives (UNEP, 2022). Furthermore, businesses can incorporate NbS into their sustainability plans, using ecosystem services to support climate adaptation, protect biodiversity, and strengthen supply chain resilience. Additionally, capabilities are crucial, as stakeholder participation plays a key role — issues like limited local stakeholder engagement, poor coordination among actors, and low stakeholder capacity can impact project success (Dubo et al. 2023).

The fourth subaction of NbS involves monitoring and governance, which should concentrate on meeting the goals established during problem analysis and planning. The governance framework presented by Matson, Clark, and Andersson (2016) for managing SES illustrates how a broad analysis of the system being transformed can be conducted through this framework. Governance quality acts as a tool to track progress in implementing and achieving NbS objectives. Effective governance played a key role in restoring drylands in

the Duwa and Sutebwo forests of Mali's Segou Region. The project employed a decentralized, participatory, and inclusive forest governance model and established two inter-communal cooperatives (Hou-Jones, Roe, and Holland 2021).

Governance levers are crucial for supporting the monitoring and governance of NbS. The effectiveness of NbS increases when they align with a country's SDG targets. For example, the case of Masdar City in the UAE, which was envisioned and is being built as a smart, sustainable urban area utilizing NbS to transform a desert landscape (Griffiths and Sovacool 2020). Since 2006, Masdar City's governance has evolved through several phases, from an initial focus on clean energy technology manufacturing to a sustainable eco-city that acts as a "holistic master integrator" of carbon-neutral solutions, fostered by partnerships, open collaborations, and research and development (Masdar 2017). Masdar City's responsive governance framework, aligned with the UAE's progressive sustainability policies like Energy Strategy 2050 and the Net-Zero by 2050 initiative, has driven its transformation. The authority granted to stakeholders such as the UAE, Mubadala, Khalifa University, NGOs, international partners, and citizens to implement NbS was crucial in Masdar City's case. This demonstrates a collaborative governance model that emphasizes consultation and co-creation (Frantzeskaki 2019), which is essential for managing and governing NbS to transform socio-environmental system.

18.2.2.2 Action Two: Accelerate upscale of proven nature-based practices and solutions

NbS need to be scaled up to be truly effective, but currently they are mostly limited to pilot projects or local government initiatives (Hartmann and Spit 2016). Involving citizen science (Fraisl et al. 2022) can help close this gap by engaging local communities in activities like data collection, monitoring, and adaptive management. This ensures NbS are adapted to specific local ecosystems and socioeconomic contexts while promoting wider adoption and support. Although NbS are typically customized to local conditions, increasing their scale offers the chance for broader impact and transformational change. A four-step framework for evaluating the potential and strategy for scaling NbS was proposed by Lebelt et al in 2023.

There are multiple pathways for scaling NbS, typically categorized into three approaches: "scaling out", "scaling up", and "scaling deep" (Salafsky et al. 2021). Examples include mangrove restoration in various coastal regions, expanding urban green infrastructure, adopting agroforestry across diverse agricultural landscapes, and conserving wetlands in different river basins. Scaling up specifically involves extensive replication of NbS across landscapes and seascapes, such as incorporating NbS into national climate policies, enacting legislation for urban planning, providing financial incentives for large-scale reforestation, integrating NbS into international development programmes, and securing corporate commitments to NbS. Addressing land restoration issues at a specific site exemplifies the scaling out of NbS. In contrast, scaling deep involves tackling the underlying socioeconomic drivers and barriers that cause ecosystem degradation, using appropriate leverage points. Ecosystem restoration must also be expanded spatially, to match the scale of widespread environmental damage, and temporally, to improve issue identification, enable adaptive management, and extend project longevity (Ren and Coffman 2023). Scaling deep of NbS entails integrating these solutions into national policies and laws, changing agricultural practices and cultural norms, and encouraging the private sector to incorporate NbS into their business models.

To create opportunities for system transformation, scaling deep requires addressing the root socioeconomic drivers of ecosystem degradation through relevant levers and by good governance. Scaling deep involves creating alternative livelihoods, addressing unemployment and integrating individual and collective action levers into NbS to reduce the drive of people to engage in illegal activities and increase participation and interests in conservation and restoration.

18.2.2.3 Action Three: Build resilience to create a self-sustaining socioecological system

Sustaining conservation, restoration, and ecosystem adaptation over the long term depends on enhancing the resilience of SES, enabling the development of self-sustaining and resilient ecosystems (Krievins et al. 2018). This is achieved by incorporating the seven principles (Biggs, Schlüter, and Schoon, 2015) into the four systematic steps for NbS (Albert et al. 2021).

To improve the effectiveness of NbS as a resilience pathway, measurable performance metrics should be incorporated into its implementation. These include ecosystem restoration targets, linked to solution

pathway 1, such as increasing vegetation cover and meeting KMGBF targets, as well as climate resilience metrics, including reduction of flood risk by a specified percentage and enhancement of water retention in NbS-managed landscapes. Socioeconomic benefits should be measured by tracking local job creation, improved livelihoods through ecotourism and sustainable agriculture, and the integration of citizen science in monitoring ecosystem health. Furthermore, carbon sequestration and climate mitigation can be evaluated through CO_2 absorption rates and expanded urban tree cover. To ensure accountability, NbS performance should be monitored using remote sensing, biodiversity surveys, and participatory approaches, aligning with international frameworks such as the Paris Agreement and SDGs.

18.2.3 Locally led adaptation and disaster risk management for enhancing socioecological system resilience

Building resilience is an ongoing process essential for a transformative shift in SES. CCA and resilience efforts require a combination of local initiatives supported by top-down policy measures, which are often missing in current state of practice. LLA actions and its eight principles (**Box 18.3**), endorsed by over 100 organizations including governments, development agencies, INGOs, and NGOs, call for a new paradigm. For genuine transformative adaptation, LLA solutions should be central to all sustainable development activities. Decades of CCA projects, often designed without considering local needs and priorities, have yielded mixed results—sometimes causing maladaptation—and have fallen short in mobilizing resources at the local level. This oversight also extends to the promotion and application of Indigenous Knowledge and Local Knowledge. These knowledge systems are deeply rooted in local contexts, often developed as NbS, and supported by scientific evidence gained over centuries through experimentation and accumulated learning. While Indigenous Knowledge and Local Knowledge are typically vital responses to climate change, they are also vulnerable to climatic impacts that could diminish their effectiveness. The LLA approach, which builds on Indigenous Knowledge and Local Knowledge might be more effective because it involves a gentler learning curve and carries a lower risk of failure or maladaptation, but the knowledge system requires identification and proper documentation, reinforced by integrating modern science, and creation of financial incentives for intergenerational transfer to youths.

LLA action, as a recent and evolving paradigm, can serve as a transformative solution if lessons are validated, standardized, and scaled across regions. It is envisioned as a model that co-achieves resilience for the human-nature nexus, adding a safety layer to prevent setbacks in conservation, restoration, and other human systems from severe climate change impacts. LLA encompasses not only CCA and DRR but also integrates net-zero energy systems, GHG mitigation, circular economy, sustainable food systems, ecosystem conservation, efficient financial pooling, and resilient critical infrastructure. For example, renewables can be deployed for climate adaptation while adaptation measures need to also account for energy security from climate risks, such as drought, heat stress and forest fires, floods, cyclones, landslides, to sustain the transformation of energy system mentioned in Chapter 16.

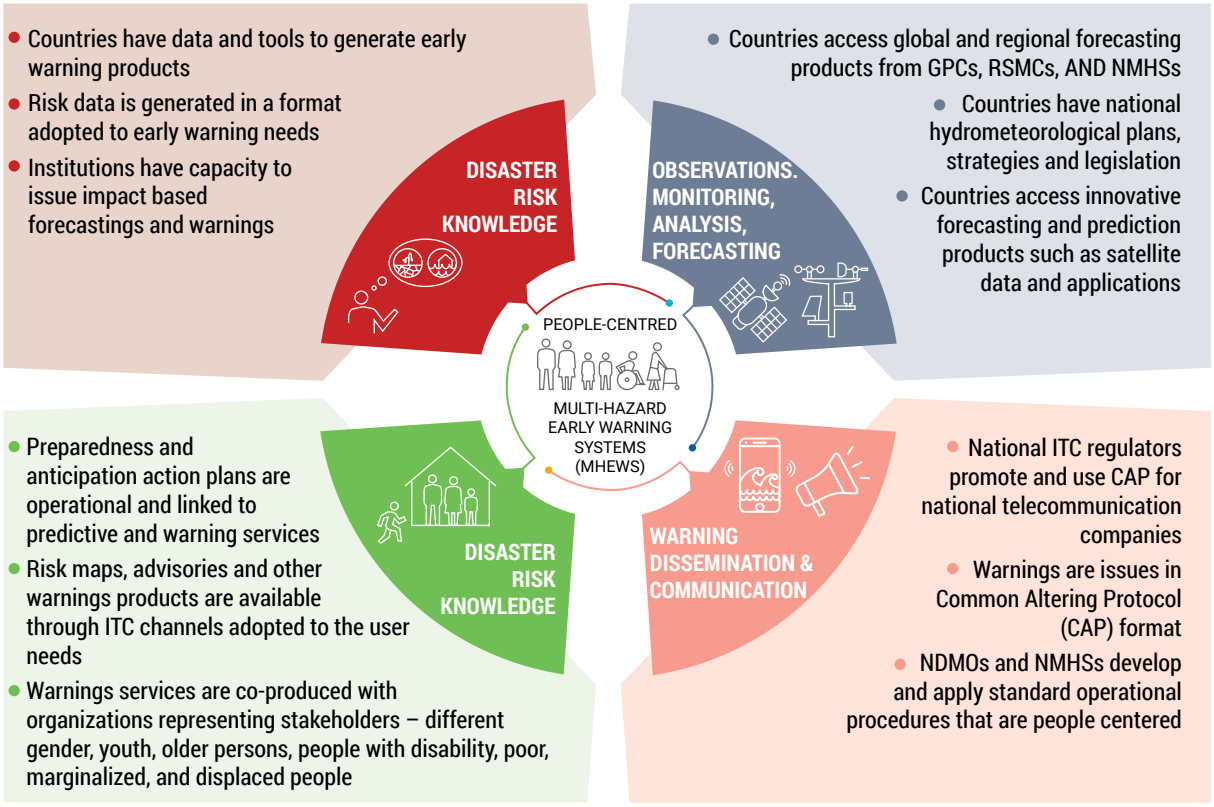
To implement this solution, this chapter suggests three sequences of actions to be undertaken over time by mobilizing sets of five levers. These actions are carried out by actors at various levels, based on available information, lessons learned, and common challenges faced in different regions. It is also crucial to incorporate the concerns of the most vulnerable groups and integrate a gender perspective to ensure that the needs and contributions of women, the elderly, children and youths, Indigenous Peoples, and other marginalized community members are fully addressed.

18.2.3.1 First Action: Enhance risk information and its communication in an inclusive manner

Risk information and communication are foundational for CCA, DRR, and minimizing loss and damage. As climate impacts are worsening and extreme multi-hazard situations, droughts, heat waves, forest fire, floods and landslides, cyclones and storm surges, become more frequent and complex, the importance of timely and correct risk information and communication has become critical for decision-making. Advances in information and communication technology, including rapid development and deployment of in situ and remote sensors, mobile apps, artificial intelligence solutions, has ushered a new era of technological and societal transformation that could be best utilized to speed-up the coverage of risk information and communication for all. International organizations, research community, governments at different levels,

private sector, as well as local communities are increasingly embracing the development, promotion, and uses of new innovations on information and communication.

Regional platform like SERVIR harnesses the power of satellite data and scientific collaboration to support healthy, sustainable communities, livelihoods and environments at local levels. The Intra-ACP Climate Services and Related Applications is an initiative for African, Caribbean, and Pacific States that aims to improve the production, access to and use of climate information, services and applications for decision makers. The Global Disaster Alert and Coordination System provides real-time alerts, impact assessments, mapping, weather forecasting, and standardized information exchange. Mobile apps and social media are connecting individuals, farmers, governments, and private sectors, providing key decision support and enabling robust feedback systems. In this regard, Early Warnings for All is an ambitious initiative by the UN Secretary-General that aims to protect everyone on



Box 18.3: Locally led adaptation actions

Local actors, including communities, Indigenous People, and local governments, are on the frontlines of climate change and other environmental problems. They often rely on their in-built responses, including Indigenous Knowledge and Local Knowledge, and frugal innovations. However, they often have a limited voice in important CCA decisions that directly affect them. LLA represents a shift from business as usual by prioritizing the involvement of local actors in all decision-making on CCA. This includes defining priorities, design of solutions and their implementation, as well as monitoring processes or evaluating successes and failures. LLA offers a transformative shift by positioning local stakeholders not as the sole bearers of adaptation responsibility, but as key drivers of catalytic adaptation solutions that are locally based, effective, equitable, and transparent.

While not all adaptation needs to be locally owned or led, initiatives like the LDC 2050 Vision, emphasize the need to channel more resources and capacity in the hands of local actors. Since social participation and ownership are not new in CCA-related interventions, LLA calls for consolidating proven best practices while addressing persistent barriers. To strengthen LLA, the Global Commission on Adaptation has developed eight principles:

- Devolving decision-making to the lowest appropriate level;
- Addressing structural inequalities faced by women, youth, children, people with disabilities, people who are displaced, Indigenous Peoples and marginalized ethnic groups;
- Providing patient and predictable funding that can be accessed more easily
- Investing in local capabilities to leave an institutional legacy;
- Developing a robust understanding of climate risk and uncertainty, drawing on a combination of local and Indigenous, generational and scientific knowledge;
- Promoting flexible programming and learning for adaptive management to address inherent uncertainty in adaptation;
- Ensuring transparency and accountability in all aspects of adaptation, including finance, design and implementation; and
- Promote collaborative action and investment to mobilize resources effectively from various sources and to enhance efficiencies and good practices (Global Commission on Adaptation 2021, Soanes et al. 2021).

Figure 18.4: Four pillars of Early-Warning-for-All initiative for effective multi-hazard early warning

Source: WMO (2022)

Earth from hazardous weather, water, or climate events through life-saving early warning systems by the end of 2027 (World Meteorological Organization [WMO] 2022) (**Figure 18.4**). Encouraging lessons are emerging on how regional cooperation in risk information and communication is essential in saving lives and property, including energy systems, from multiple hazards. However, there is a missing link between regional, national, and local capabilities when it comes to enabling reliable access to risk information and communication. For instance, farmers and pastoralists use Indigenous Knowledge or methods of weather forecasting alongside scientific forecasts for decision-making, such as through citizen science approach, to cope with climate change impacts (Nkuba et al. 2023). The knowledge and innovation levers play a significant role in transferring and adopting the latest innovations, such as providing satellite connectivity in remote or disaster-affected areas. Additionally, they promote Indigenous Knowledge and Local Knowledge that are grounded in science or have strong sociocultural support.

Meanwhile, economics and finance levers, like the Adaptation Fund or the newly established Fund for responding to Loss and Damage under the financial mechanism of UNFCCC, can be mobilized to finance technology adoption. This funding is crucial for activating other levers, including individual and collective action, knowledge and innovation, and capabilities, which generally take longer to implement. For example, successful deployment of an early warning system depends on clear protocols and mechanisms to turn warnings into timely, coordinated actions on the ground. Strengthening community-level response capacity ensures warnings are not only received but also effectively used for response to the events.

Similarly, regional organizations, research communities, and the private sector can focus on developing services, such as impact-based forecasting, centred on risk information and communication. Meanwhile, central and subnational governments, along with community-based organizations, can promote the adoption and use of the system. A two-way risk communication system should be established that is both responsive and adaptive to reduce losses and damages to people and nature. The faster progress is made on this action, the earlier significant progress on transformative adaptation will be made.

18.2.3.2 Second Action: Formulate integrated interventions to enhance the resilience of SES, while enabling climate-resilient development

Climate-resilient development can enhance capacity for climate action, including GHG reductions and the implementation of CCA options that boost social, economic, and ecological resilience to climate change (IPCC 2022). Therefore, climate-resilient development and strengthening the resilience of SES require integrating all synergistic approaches for CCA, net-zero strategies, DRR, addressing loss and damage, ecosystem conservation and restoration, sustainable bioeconomy, and related efforts. In addition to improving risk information and communication, it is important to acknowledge a combination of infrastructure and processes that have shown promising results but face barriers to widespread adoption. These include EbA and ecosystem-based DRR (UNEP 2021). These solutions should be tailored to the local context, designed for replication, and structured to encourage cross-fertilization, knowledge-sharing, and regional collaboration. Many initiatives and practices, both newly evolving and established, from local to regional levels, are available but still need consolidation. Available economics and finance levers, particularly the increasing number of large and small climate change funds under UNFCCC, the United Nations, multilateral development banks, governments, independent, and private sources require major consolidation to avoid duplication. Examples include the Green Climate Fund, Global Environmental Facility, Adaptation Fund, WB Climate Change Action Plan, ADB Climate Fund, Germany's International Climate Initiative, UK International Climate Finance, Climate Justice Resilience Fund, Patagonia Environmental Grants Program, Clean Technology Fund, and Amazon Climate Pledge Fund, among others.

LLA aims to facilitate a systematic flow of funds and resources from available sources to the local level efficiently. It is essential to prioritize a set of climate-smart interventions supported by existing financial instruments, which may be risky from a traditional cost-benefit perspective but are crucial for preventing the "soft limits" of adaptation from becoming "hard limits." These initiatives also lay the groundwork for inclusive climate-resilient development. Three key conditions are particularly relevant. First, addressing the immediate risks posed by climate change impacts, such as droughts, heat stresses and wildfires, that are widespread and affect sectors such as farming, health, transport, energy, and ecosystems. Second, implementing proper safeguard measures to compensate climate victims is vital to support building back better, promote transformation, and enhance resilience. Finally, climate-resilient development should broaden options for socioeconomic opportunities at the local level to enhance resilience and societal well-being in harmony with nature. Supported by economics and finance levers, much can be achieved through the effective use of knowledge and innovation levers, such as local innovation that integrates modern science to strengthen Indigenous Knowledge, traditional knowledge, and local knowledge, along with the rapid adoption and localization of interventions. Notable examples where knowledge and innovation levers have played a key role include NbS, community-based adaptation, climate-smart farming, solar panel use in agriculture (agrivoltaics) and rooftops, providing shading, decentralized access to clean energy, and creating additional income as prosumers, microcredits, crop or livestock insurance, and digital literacy.

Success often depends on local buy-in, primarily driven by effectively utilizing individual and collective levers. These levers are most effective when they motivate meaningful stakeholder participation across various levels. The capability and individual and collective levers are crucial for establishing frameworks that support monitoring, reporting, and evaluation. Capability lever not only facilitate the implementation of CCA interventions but also help generate socioeconomic opportunities, especially for youth. This includes promoting local entrepreneurship or start-ups related to CCA services, such as financial literacy, marketing skills, or local manufacturing of tools based on Indigenous Knowledge and Local Knowledge, extension, and advisory services. The successful implementation and replication of certain practices, such as climate-smart farming, is often determined by how well these capabilities are built, retained, used and embedded into local policy, planning, and decision-making.

18.2.3.3 Third Action: Rapid upscaling and institutionalizing of locally led adaptation interventions

The main challenge in transformation lies in implementing the identified LLA solutions quickly and at scale (Chapter 21), while ensuring sustainability. The approach is very adaptable, with all five levers and involved actors working together to overcome barriers, challenges, and trade-offs that may arise during implementation. It also aims to create synergies

that deliver sustainable benefits for people, nature, and the broader system economy.

Creative approaches are needed first to achieve the desired speed and scale of implementation. The previous two actions form the short- and medium-term focus, where a lot of innovation, trials, learning, and replication occur, laying the groundwork for long-term transformation.

In this third step, governance lever plays a crucial role by shaping the direction of change. Practical actions are needed to bridge the gap between upstream policy decisions on climate change – such as the National Adaptation Plans, National Climate Change Policies, and Nationally Determined Contributions – and the beneficiaries of these policies. Prioritizing capacity development alongside individual and collective action levers is vital for raising awareness and integrating national and international decisions at the local level. A clear example of this challenge is the difficulty in implementing adaptation communication to monitor Global Goal on Adaptation under the Paris Agreement, highlighting the disconnect between policy formulation and practical application. Mainstreaming must also include the localization of important biodiversity and SDG-related policies and targets in a coordinated way. This approach can benefit both governments and key stakeholders by aligning policies and actions across all levels. Firstly, it facilitates pooling resources for climate action, SDGs, DRR, biodiversity conservation, and ecosystem restoration. Secondly, it enables stakeholders, especially local beneficiaries, to align their priorities with national and international policies and to communicate their concerns and needs to decision makers upstream. While these considerations are often included during project and programme planning, they are frequently poorly executed due to time constraints and institutional barriers. Therefore, over time, a strong institution supported by capabilities, economics and finance, and knowledge and innovation levers will be necessary to improve coordination across different decision-making levels.

18.2.4 Acceleration of the circular economy transition through innovative bioresources and deployment of a sustainable bioeconomy infrastructure

Five actions are identified, along with levers and actors for transformational change as part of an effective solution pathway. These actions align with bioeconomy strategy development worldwide, with 23 countries already having an active bioeconomy strategy and 15 countries in the process of developing one (FAO 2024). See also **Box 18.4** for drivers and principles guiding a sustainable bioeconomy.

18.2.4.1 Action one: Accelerate the transition to a circular bioeconomy

The shift to a circular economy focuses on maintaining a continuous flow of resources within either technical or biological cycles. Its goal is to keep resources – such as energy, fuels, metals, plastics, and synthetic chemicals – within these cycles through recovery, restoration, and smart utilization using advanced technologies and effective regulation (**Figure 18.5**). This is especially critical for the mining industry, notably concerning energy transition minerals, as explained in Chapter 16.2.4. Developing a sustainable circular bioeconomy supported by suitable infrastructure is essential for reducing waste and maximizing resource efficiency (Geissdoerfer et al. 2017; IRENA 2020).

Likewise, food systems need to implement sustainable and regenerative practices that boost biodiversity, conserve Indigenous and local farming methods, lower GHG emissions, and enhance soil health (Chapter 17) (FAO 2018; IPCC 2019). Central to these efforts are knowledge and innovation and individual and collective levers. In the short term, developing and deploying technologies for resource recovery, biobased materials, and waste-to-resource conversion is vital to increase circularity. Additionally, collaborating with Indigenous Knowledge holders, who have extensive resource stewardship practices, is crucial to ensure bioeconomy strategies are effective and respectful of ecological limits. In the medium term, advanced technologies like artificial intelligence and blockchain can help monitor resource flows and increase transparency in supply chains. By harnessing diverse knowledge systems and scientific progress, society can establish resilient, circular economies that support both people and the planet in the long term.

The goal of reducing natural resource depletion by advancing a circular economy through innovative bioresources and bioeconomy infrastructure is to establish a sustainable system that minimizes waste, enhances resource efficiency, and helps restore natural

ecosystems. This strategy includes several vital components and strategies. The impact of production systems is profoundly local, as they influence nearby communities and their environments by depleting resources and using ecosystems as pollutant sinks via discharges and waste disposal (Geissdoerfer et al. 2017; Kirchherr, Reike, and Hekkert 2017). This degrades local ecosystems and damages the health and livelihoods of local populations (Rockström et al. 2009; Steffen et al. 2015).

Overall, accelerating the bioeconomy requires the combined action across knowledge and innovation, individual and collective and governance levers to enable effective transformational solutions. There is a significant policy commitment to the concept of the bioeconomy, with some technologies already in use, but deploying bioeconomy innovation at scale remains challenging.

18.2.4.2 Action Two: A regulatory environment to ensure biofeedstock supply is environmentally sustainable, avoids trade-offs with biodiversity, food and water resources

A strong and coherent regulatory environment, with central governance levers globally recognized and effectively implemented, is key to the successful deployment of a sustainable bioeconomy. Despite significant efforts, the regulatory environment is fragmented. This requires urgent short-term action. Sustainability metrics that quantify full life cycle impacts of direct and indirect effects of bioresource cropping, including on GHGs, biodiversity and ecosystems services are now well-understood, but require effective implementation. Direct effects refer to all life cycle effects on the immediate system in which the crop is grown, such as tractor operation and fuel used to grow the crop as well as environmental

Box 18.4: Drivers and principles to ensure a future sustainable bioeconomy

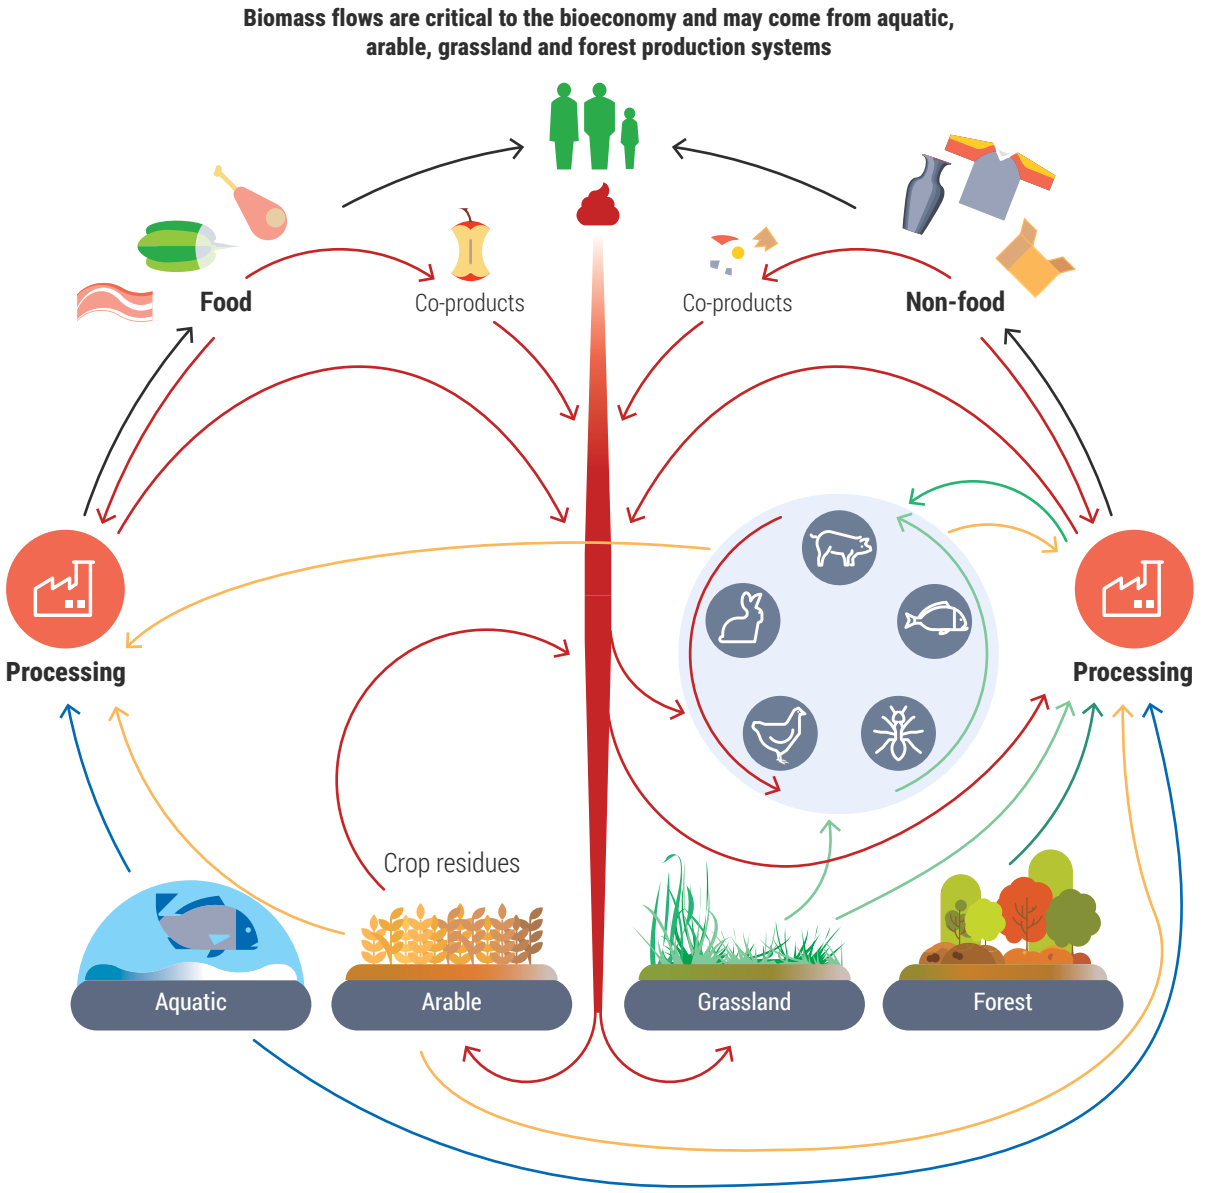
The bioeconomy refers to the production, utilization and conservation of biological resources, including plants, animals and microbes, alongside derived biomass and organic waste, across many economic sectors, including agriculture, energy, chemicals, and pharmaceuticals. It plays an essential part of the circular economy, detailed in Chapter 15. While bioeconomy pathways vary by sector, process and geography, they are linked using biological resources to support a low-carbon, sustainable economy (Tan and Lamers 2021). Five ecological principles to guide biomass use for a sustainable bioeconomy are:

- Safeguard and regenerate healthy ecosystems: source biomass sustainably, avoiding depletion of natural capital, through use of marginal land for bioeconomy development.
- Avoid non-essential products and reduce waste of essential ones.
- Prioritize biomass use appropriately. For example, avoiding the use of first-generation food crops for biofuel and avoiding direct and indirect land-use effects; thus, identifying land for food crops.
- Utilize co-products/waste from agroecosystems first: use by-products like straw or manure, and other resources, which may otherwise be lost or misused, such as straw burning.
- Minimize energy footprint and use renewable energy. Apply life cycle assessment methodology to ensure the energy and carbon footprint of the proposed bioeconomy system is significantly lower than fossil fuel-based alternatives (Muscat et al. 2021).
- Drivers enabling bioeconomy development and deployment:
- Low-carbon technologies to address climate change goals and climate mitigation

- More efficient use of planetary resources
- Integration into the circular economy
- Advances in biotechnology, such as engineering microbes, plants and animals are enabling new opportunities
- Regional governance driving innovation and deployment

Key barriers to sustainable bioeconomy deployment:

- Inconsistent biomass supply, especially year-round at a reasonable price
- Logistics of biomass transportation
- Infrastructure and storage limitations
- Technology scaling and gaps in chemical engineering knowledge
- Limited financial resources and financial models to enable investment and commercialization
- Capital investment requirements are high
- Immature regulatory environment and lack of global standards
- Weak market demand for products due to higher costs



Absence of governance and policy support, ensuring sustainability standards are met, lack of skilled workforce, lack of public understanding and awareness

Bioeconomy case examples: The International Energy Agency provides a global summary of biorefinery research and deployment activities (IEA 2022).

One notable example is from the Kingdom of the Netherlands, where the company Avantium is advancing the use of plant-based resources for sustainable chemical production. Their vision includes production of plant-based plastics made from plant sugars, to replace glass bottles, aluminium cans and multilayer packaging, as well as capture of carbon dioxide and using it to produce formic acid, a preservative and antimicrobial chemical, and oxalic acid, a chemical derived from plants with use for cleaning. These high-value chemicals have a wide range of applications and are traditionally made from fossil fuels. The novel carbon-negative polymers are compostable, degradable, recyclable.

In linking such biorefinery deployments to restored natural capital, life cycle analysis demonstrates that, from cradle to grave, the GHG emissions of the biorefinery processes have significantly lower greenhouse gas emissions than their fossil- based alternatives, relative to alternative systems (Eerhart et al. 2012). It is widely acknowledged that to avoid potential conflicts around land for food and energy, the bioeconomy must shift to second generation non-food fibrous and woody crops. Equally important is to establish better links between the biorefinery activities and natural capital enhancement.

Figure 18.5: Biomass flows are critical to the bioeconomy

Source: modified from Muscat et al.(2021)

costs of fertilizer from which bioenergy resources are grown or extracted (IEA 2024). In contrast, indirect effects, recognized for several years (Bourguignon 2015) may occur as unintended consequence of bioresource cropping, for instance if food crops are displaced to high-biodiversity landscapes due to land conversion elsewhere (Sanchez et al. 2012).

However, the direct and indirect impacts of bioenergy cropping vary by geography, land availability, culture and management practices. Several regional and global standards for bioenergy cropping, such as the GBEP – the Global Bioenergy Partnership and the Roundtable on Sustainable Palm Oil, provide a framework to ensure sustainability criteria are met, particularly for direct land-based impacts, focused on GHG emissions reduction and ensuring sustainability. Recent technological expansion has been focused on non-food lignocellulosic (fibrous and woody crops)-fast-growing trees and grasses, with improved GHG balance (Harris, Spake, and Taylor 2015) and enhanced biodiversity (Donnison et al. 2021). However, these regulatory bodies are voluntary, leaving significant risk, given the increasing future demand for bioresources. There is a pressing need for explicit and enforceable frameworks for defining sustainable bioenergy crops, encompassing the management of natural resources, transparency and science-based carbon accounting, protecting and enhancing biodiversity and supporting and protecting communities, such as that proposed

by the Glasgow Declaration on Sustainable Bioenergy and IEA offer promising models.

In addition to biodiversity, a significant risk of water over-extraction remains for bioenergy, as well as for other crops. In the face of a changing climate, this should also be acknowledged, as identified by IPCC (2019). Levers required to ensure this action are governance and knowledge and innovation.

Evidence shows that poorly designed supply chains are an example of how bioenergy has the potential to go wrong and harm biodiversity, especially when bioenergy crops replace natural grasslands or forests (Desiree et al. 2013; Immerzeel et al. 2014; Núñez-Regueiro, Siddiqui, and Fletcher Jr 2021). Improved governance of bioresources is essential to ensure a sustainable bioeconomy and to protect biodiversity. A consensus is forming on designing biocropping systems that promote biodiversity across various landscape types. Sustainable bioenergy crops should be expanded and integrate innovative agricultural practices. These include:

- cover cropping
- shifting to perennial crops
- optimizing water and input use
- new crop varieties requiring fewer inputs
- adopting technology-driven practices as part of climate-smart agriculture

Cropping management should aim to stop biodiversity decline while incorporating transformative technologies like the widespread adoption of precision-engineered or gene-edited feedstocks. Most of these actions require better governance alongside individual and collective action levers. For instance, governance is essential to establish policies that incentivize changes in agricultural practices, such as payment for ecosystem services (Farley and Costanza 2010) and soil health initiatives (Eastburn et al. 2017). Farmers and communities must adopt change, reassess their environmental values, and produce goods in a new manner that promotes the flow of biomass from food to residues and processing.

The bioeconomy plays a crucial role in the sustainable circular economy (Chapter 15). It offers substantial potential to deliver transformative solutions – replacing fossil fuels with biomass-based energy, manufacturing, and processing – while also addressing climate change. This includes restoring natural capital, as well as advancing fuel, food, chemicals, and agricultural innovations, enhancing supply chain resilience, improving human health, and fostering cross-cutting advancements (The White House 2023). Achieving future success depends on rebuilding global natural capital (Tan and Lamers 2021). Future efforts should focus on identifying suitable land for bioenergy crops at the national level and streamlining fragmented global governance approaches to ensure the broad sustainability of this emerging resource (**Box 18.5**).

18.2.4.3 Action Three: Developing new and novel bioresources: plants, animals and microbes

The global demand for diverse types of bioresources will be substantial. For instance, in the United States of America alone, 1.2 billion tons of biomass annually are proposed for sustainable aviation fuel and to support a robust bioeconomy (Langholtz, Stokes, and Eaton 2016; The White House 2020). Recently, the fastest-growing biomass application is wood pellet production for low-carbon electricity, reaching over 44 million tons in 2021 and, up from 18.1 million tons in 2012 (World Bioenergy Association 2022). Effective crop and land management, along with crop breeding, can play a crucial role in supplying new bioresources for this expanding bioeconomy. A better understanding of the genetic and environmental factors influencing feedstock yield and quality is essential, especially through technological and future innovations. This highlights the need for developing crops that require less water, nitrogen, and phosphorus, while also lowering GHG emissions (Chen et al. 2019). Additionally, improving animal- and microbial-based systems is necessary to reduce their GHG footprint, which will require advances in biotechnology. Microbes play a crucial role in promoting a sustainable bioeconomy by enhancing biological carbon sequestration, facilitating more efficient microbial pathways for converting feedstock into fuel, remediating hazardous substances and wastes, and engineering crops with symbiotic bacteria for nitrogen fixation (Peixoto et al. 2024).

Waste-derived feedstocks should also be used, enabling the combined use of sustainable sources to produce environmentally friendly aviation, maritime, and other fuels that are difficult to supply through other technologies (Bioenergy Technologies Office

Box 18.5: Bioenergy and Carbon Capture and Storage: concerns for the environment

- Widescale deployment of bioenergy has the potential to deliver multiple low-carbon energy solutions, for heat, power and liquid biofuel, with or without associated carbon capture and storage. The demand for bioenergy is projected to increase in all GEO-7 scenarios (Chapter11), in line with other assessments. It is especially prominent in the GEO-7 Transformation Scenarios where bioenergy with carbon capture and storage (BECCS) is applied to help achieve the UNFCCC-Paris target of 1.5°C in 2050 without overshooting the target, or where the target is overshot and BECCS is used to return to the target. However, the amount of BECCS required is less in the behaviour-focused scenario compared to the technology-focused scenario. The unique and appealing feature of BECCS is that it produces both energy and negative emissions. The amount of BECCS required depends on several factors including the degree to which the energy system is decarbonized prior to 2050, and the amount of energy required after 2050 and how effectively biomass can be used for multiple purposes as part of an emerging bioeconomy (Chapter 15).

- The land use and potential consequences for the environment associated with this demand for BECCS is significant, but earlier estimates of the technical potential of over 2 billion hectares of land (Slade et al., 2014; Haberl et al., 2010; UKERC, 2011), has now been significantly reconsidered because of limitations associated with sustainability trade-offs. These trade-offs relate to loss of biodiversity, water use, and to conflicts with land needed for growing food, NbS, indirect land-use change, and conservation, according to recent estimates for land needed for effective bioenergy and BECCS purposes (IPCC, 2018, 2023; Chapters 16 and 17). The two scenarios of GEO-7 both commit less than 100 million hectares of land to BECCS, in contrast to earlier assessments that predicted much higher land demand.

- The use of land resources to address energy, food and nature is critical for effective transformative solutions identified throughout this GEO assessment. Potential supply of biomass for BECCS is also dependent on the emergence of new technologies, including biotechnologies that deliver highly productive non-food, fibrous and woody crops. Some biomass material is already available from agricultural and forestry residues and other waste materials that do not compete with food and feed. Governance and management of these trade-offs will be key to a future sustainable bioeconomy with BECCS as an appropriate technology.

Credit: ©UNEP

2024). Similarly, these feedstocks can be utilized to synthesize high-value chemicals, pharmaceuticals, and polymers, replacing traditional products and offering biotechnological solutions for a broad range of issues, such as bioengineered foods like milk and meat, and replacing fossil hydrocarbon-based materials with bioresource-based alternatives (Muscat et al. 2021).

Sustainably sourced and cultivated feedstocks are needed on a large scale, and this demand is expected to continue rising. Society is entering an era where more biomass has been harvested than ever before (Foley et al. 2011; Krausmann et al. 2013). It has been estimated that global biomass demand could triple in the coming decades. An essential solution pathway for establishing a sustainable bioeconomy involves identifying, sourcing, and managing new, sustainable global biomass resources. Consequently, biomass feedstocks will be increasingly needed for various applications in the future bioeconomy, as outlined in **Table 18.2**.

Engineering biology provides valuable knowledge and innovative prospects for the bioeconomy. Creating new and unique feedstocks and bioresources through biotechnology, as well as traditional methods like identification, sourcing, breeding, selection, collection, and pre-processing, is essential for advancing the bioeconomy. Traditional plant breeding typically yields about a 10 per cent increase per decade. However, the availability of new biotechnological approaches – such as engineered feedstocks from gene editing in plants, animals, and microbes – will enable paradigm-shifting developments. These include improvements in plant chemistry for bioprocessing, increased production of necessary chemicals, and yield enhancements, which are already beginning to emerge (Ricroch, Clairand, and Harwood 2017; Zhang et al. 2019).

Novel new sources of biomass are also needed to support the shift to more plant-based diets, including increased production in plant-based proteins from legumes such as peas, beans and chickpeas, as well as

Table 18.2: Projected biomass feedstock requirements

Bioproduct	Potential demand for feedstock biomass to 2050
Bioenergy heat and power	Global demand is increasing. 300-600 million ha of wood-based bioenergy cropping is possible (Lauri et al. 2014; Fuss et al., 2018), providing 5-250 Exajoules per year by 2050 (IPCC, 2023).
BECCS- Bioenergy with carbon capture and storage	Will be needed to meet the 1.5°C target for global warming by 2050. Requires 200-600 million hectares (IPCC 2023, IEA 2024). In the target-seeking scenarios of GEO-7, less than 100 million ha is required due to the extensive use of waste co-products.
Biogeochemical sequestration – carbon dioxide removal technologies	Fast-growing trees and afforestation, several hundred million to 1 billion hectares required, depending on tropical, temperate and boreal contributions.
Sustainable aviation fuel	Rapidly increasing demand with 400 million tons per year required by 2050. Signif-icant amounts will come from waste and co-product streams but dedicated crops will become increasingly important. E.g. in the US, 10-12 million hectares required to supply 3 billion gallong per year by 2030.
Plastics, chemicals, pharma	Currently three million hectares for bioplastics (European Bioplastics 2024).
Protein production, plant-based meat, plant-based dairy, plant-based proteins in processing	A UNEP report cites land use as lowered, 100m2 per 100g protein in animal-based meat, versus 5-15 m^2 per 100g protein in plant-based (Santo et al. 2020).
Regenerative agriculture, mulches, better use of animal co-products, anaerobic digestion, biogas, biochar	With a goal to reduce GHG emissions by up to 30 per cent, these measures occur on land already allocated to food production and as such this is not additional land. This may be less than 1.5 per cent of total agricultural land of total agricultural land or approximately 5 billion hectares

grain crops, such as wheat and fast-growing duckweed (UNEP 2023). Novel bioprocessing are emerging, for example, cultured meat and milk, some of which are already available commercially in some parts of the world (The Economist 2023) and likely to become more widely acceptable (Kirsch 2023). Laboratory-based cultured milk, produced through precision fermentation without the use of grazed dairy livestock that emit significant methane, or plant-based milk alternatives made from almonds, which requires large amounts of water, may provide more sustainable alternatives. For example, the company Turtle Tree, is developing a novel process to mass produce lactoferrin, a key milk protein. Similarly, Shiok Meats in Singapore (Singapore Global Network 2021) is commercially producing cultured seafood by extracting stem cell from shrimps, prawn and lobster to generate cell-based laboratory protein. However, a note of caution remains that these ultra-processed foods may carry a significant environmental footprint, and current research is limited. Likewise, the impacts of lab-grown food on human health are unclear. There is limited peer-reviewed research in this rapidly evolving field, and regulatory frameworks are still being developed. Nevertheless, key technologies to watch for in the future include the knowledge and innovation lever, which remains essential for success. It works in conjunction with the capability lever, which is necessary for developing new skills.

18.2.4.4 Action Four: New infrastructures and technologies for the future bioeconomy

Bioeconomy infrastructure deployment encompasses establishing and executing essential systems, technologies, and frameworks that underpin the bioeconomy. This process involves constructing facilities, such as biorefineries, for converting biomass into valuable products, as well as developing supply chains, networks, and logistics that facilitate the efficient collection, processing, and distribution of biobased products.

Early investments from public and private sectors are essential for supporting high-potential solutions using economics and finance alongside governance levers. New sustainable biorefineries are crucial for scaling the bioeconomy. In the EU, over 130 woody biomass-based biorefineries are operating, with more planned. Financial investments are rising in these industries, and in the US, the Inflation Reduction Act in 2022 provided significant new government funding, totalling US$800 billion to help accelerate the development of the bioeconomy, including scaling up innovative technologies such as using municipal solid waste to produce sustainable aviation fuel, a sector that is difficult to decarbonize. A sustainable aviation fuel blending credit is available to encourage this market, provided the process achieves a 50 per cent reduction in GHG emissions compared to standard jet fuel. Many less favoured liquid biofuels can connect this technology to carbon capture and storage systems to reduce life cycle GHG emissions, thereby boosting the value of the fuel in states like California, Oregon, and Washington.

Despite these positive examples, action is needed to support the development of new infrastructures for the bioeconomy. The petroleum industry has benefited from over a century of research, which has shaped the development of a complex hydrocarbon chemical industry (Fitzgerald, 2017). This suggests that the transformational changes necessary to develop a new bioeconomy with such sophistication will take many decades unless concerted, solutions-focused actions are taken to enable rapid change. Biorefining is a key component of the circular bioeconomy, with multiple biorefining pathways identified, comprising four key elements: feedstocks, processes, platforms, and products (IEA, 2022). Multiple bespoke solutions are necessary to foster a circular economy and support the widespread deployment of commercial biorefineries globally. Overall, much of the infrastructure needed to establish these new biobased industries remains undeveloped. In this context, the economics and finance lever plays a central role alongside the governance lever. The sustainable biorefinery is central to the emerging concept of a circular economy, and multiple types of biorefineries are emerging. Some are at the conceptual and research scale, while others are already being deployed commercially (Budzianowski 2017). The International Energy Agency provides a global review of biorefinery research and deployment activity (IEA 2022).

18.2.4.5 Action Five: The bioeconomy that addresses wide societal issues with significant change in governance to support the circular economy to rebuild natural capital

Moving towards a new type of biobased industry is challenging, and stakeholders, including policymakers, innovation supporters, and others, need to explore and develop this space (Bioenergy Technology Office 2017; Schipfer 2024). Significant behavioural and social change, facilitated through the individual and

collective action lever, will be required to transition towards a circular economy, including the training and development of a newly skilled workforce via the capability lever. A strong and growing bioeconomy will need a new workforce with skill sets developed in the short term and deployed across the medium and long term. Technical educational qualifications may need to change, delivering graduates with less emphasis on academic knowledge and stronger technical skills to meet the rapid changes in skill sets required for the bioeconomy. As the demand for skilled workers grows, there will be a need to reskill and retain more people, which requires expanding capabilities. This new workforce should be diverse, supported by the creation of high-quality jobs, and often rooted in rural communities if biorefinery or bioprocessing hubs are established in the region. Developing this workforce will vary by location, and innovative partnerships are essential to ensure equitable access to the benefits of a future bioeconomy. Collaborations with local and Indigenous People and including Indigenous Knowledge can enhance opportunities for sustainable, long-term employment and improve well-being by promoting new skill sets in handling, transforming, and utilizing biomass resources, as well as operating new biobased infrastructure, shifting away from traditional fossil fuel-related skills.

External influences by companies can disrupt traditional methods of natural resource use in forest communities, potentially causing social tensions (Halonen, Näyhä, and Kuhmonen 2022). However, these influences also hold the potential to be positive and transformative, introducing new, innovative approaches through government regulations, altered financial mechanisms, and emerging technologies. Achieving this requires a clear social licence to operate, co-creation and active engagement with local communities. Innovation is essential for building a sustainable bioeconomy in the future. Educating consumers about the advantages of a circular economy and promoting sustainable consumption can increase demand for circular products and services (Hobson and Lynch 2016; Lieder and Rashid 2016).

18.2.5 Enabling adaptive and transformative governance of socioecological systems

Finally, upscaling and strengthening the resilience of SES, biodiversity conservation, and restoration, while advancing the bioeconomy, requires innovation in governance across and within multiple levels. It involves governance with multiple, overlapping decision-making centres that operate at different scales, promoting more adaptive and inclusive management of SES (Berkes 2007; Ostrom 2010) (**Box 18.6**). This model empowers local communities to participate in governance, ensuring that their knowledge and needs are integrated into broader policy frameworks (Folke et al. 2005; Armitage, Berkes, and Doubleday 2007). Collaboration among local, regional, and national levels, promotes adaptive, decentralized decision-making, fostering inclusive and context-specific solutions that enhance overall system resilience and sustainability (Folke et al. 2005; Ostrom 2009). These integrated solutions align biodiversity conservation, sustainable management of natural resources, climate adaptation, and innovative governance with a circular economic system to create a more resilient and sustainable future for all (Rockström et al. 2009; IPBES 2019).

18.2.5.1 Action One: Enhancing local decision-making through inclusive stakeholder engagement and capacity development

Local communities – including rural and urban neighbourhoods, local enterprises and businesses, and active participation from organizations such as non-governmental groups, civil society, Indigenous Peoples, women, and older people, among others – are central to improving decision-making at the local level through co-creation. Government institutions at the local, regional, and national levels serve as vital facilitators, providing the regulatory frameworks and oversight necessary for effective governance. Additionally, NGOs and civil society groups support and reinforce local decision-making processes.

Financial institutions, such as banks, microfinance organizations, and investment funds, are an EF lever that play a crucial role by providing funding mechanisms and financial tools to support local initiatives and ensure their long-term sustainability. Additionally, international organizations and donors contribute resources and technical support, helping to adapt global best practices to regional settings. Academia and research institutions also support the process by supplying data, research, and innovative ideas, which aid in evidence-based decision-making at the local level through the STDK lever.

The success of enhancing local decision-making capacity depends on the effective use of EF levers. In the medium

Box 18.6: Adaptive and transformative governance

Governance refers to the mechanisms and processes through which society makes collective decisions, sets shared goals, and takes coordinated action to achieve those goals. It encompasses the relationships between government and society, including the means through which private actors, markets, and interest-based networks influence policy decisions. Adaptive governance has emerged as a response to climate change and uncertainty, enabling societies to adapt to changing conditions. Transformative governance goes a step further, aiming for a fundamental reorganization of system's underlying structures and controlling mechanisms.

While adaptive governance and transformative governance differ in scope, these approaches share characteristics and can be considered different points on the same spectrum of governance. Both forms of governance require diverse individual and organizational actors operating at different levels of a SES, connected through formal and informal networks. Both require distributed structures such as polycentric governance, robust information exchange, consistent evaluation, and a culture of innovation, experimentation and learning. Transformative governance is needed when SES conditions reach adaptation limits, threshold is crossed, or a regime shift results in ecosystem degradation or increases social inequality. In such cases, governance needs to enable transition towards a more desirable system state with greater production of services and greater social equity (Chaffin et al. 2016).

term, public-private partnerships will be promoted, allowing local businesses to work with larger corporations and government agencies on mutually beneficial initiatives. Additionally, creating localized economic incentives, such as tax breaks or subsidies, will attract investment into sustainable, community-driven projects. In the long term, robust financial mechanisms, such as regional investment funds or climate resilience funds, will be established to provide ongoing financial support for local initiatives. National policies will be integrated with local financial frameworks to ensure the alignment of priorities. Some examples below.

- Short-term example: Microfinance programmes (1-2 years). In Kenya, microfinance institutions like Kenya Women Microfinance Bank offer small loans to women-led businesses and farmers, empowering local entrepreneurs to launch and expand small enterprises, which boosts local economic resilience.

- Medium-term example: Public-private partnerships (2-5 years). The Colombian project Agua Somos is a collaboration among local water utility companies, private firms, and community organizations aimed at promoting sustainable water management. By merging public funding with private sector expertise, this initiative ensures active community participation in decision-making and delivers efficient services.

- Long-term example: Regional investment funds (5+ years). The European Union's Cohesion Fund has consistently supported member states by funding regional projects aimed at reducing economic disparities. Regarding the SC levers, immediate short-term actions will focus on activating existing social networks and utilizing local cultural norms to encourage participation and acceptance of inclusive governance.

Public awareness campaigns will emphasize the advantages of multi-stakeholder involvement, employing culturally appropriate messaging for broad acceptance. In the medium term, ongoing efforts will focus on strengthening trust between local communities and external stakeholders, including businesses and government agencies. This will be accomplished through ongoing consultations and dialogues that respect local customs and traditions, ensuring that all voices are heard. Over time, these initiatives will foster the development of institutionalized multi-stakeholder platforms that encourage transparency, collaboration, and accountability in governance.

- Short-term example: Awareness campaigns and community mobilization (1-2 years). In Indonesia, community-based coastal management programmes, like those in Aceh, have successfully mobilized local fishing communities to participate in ecosystem conservation.

- Medium-term example: Building trust through consultation (2-5 years).

- In Brazil, the Chico Mendes Extractive Reserve involves local communities in sustainable forestry through formal consultation processes that guarantee their participation in decision-making. Trust is fostered by incorporating local knowledge and encouraging transparent dialogue between communities, businesses, and government, leading to stronger, more effective local governance.

- Long-term example: Establishing multi stakeholder platforms (over 5 years). The Philippine Local Development Councils are mandated bodies that unite civil society, government, and the private sector to promote participatory decision-making at the local level. Over time, these platforms have become an integral part of governance, embedding inclusivity into local policies.

A key focus is on developing capabilities that enable local actors to participate effectively in decision-making, such as improved leadership and facilitation skills, financial and entrepreneurial training, project management and monitoring skills, data and analytics skills. Training will highlight the importance of long-term planning, sustainability, and effective policy implementation to ensure a future, better-skilled workforce.

- In the short term (1-2 years), initial efforts will focus on leadership development and financial skills training for local actors. For instance, in Rwanda, the government's Umuganda programme encourages civic participation by training local leaders to oversee public projects, such as constructing infrastructure or implementing environmental conservation initiatives. Train local leaders in facilitation, conflict management, and leadership skills, empowering them to lead community development initiatives.

- Medium-term efforts (2-5 years) will focus on enhancing project management and data analysis skills. In India, the Smart Cities Mission educates local authorities on managing and tracking urban projects using data-driven decisions. The goal is to equip local actors with the skills needed to design, oversee, and monitor local initiatives.

- Long-term (5+ years) capabilities will concentrate on embedding policy and governance skills at the local level. For example, in Mexico, the National Institute for Federalism and Municipal Development offers ongoing training to local government officials, ensuring that governance remains participatory and efficient. Provide long-term governance training that enables local decision makers to incorporate local concerns within national policy frameworks.

18.2.5.2 Action Two: Vertical integration of local and higher governance levels for facilitating the flow of resources and support

Vertical integration between local governance structures and higher levels of government is vital for ensuring that resources, expertise, and policy support flow seamlessly to enable effective local decision-making. This integration requires collaboration among local communities, local and national governments, private sector actors, international organizations, NGOs, and research institutions. By linking the local level with regional, national, and international systems, local actors can access the financial, technical, and policy assistance needed to promote sustainable development initiatives aligned with broader strategies.

The flow of financial resources is a fundamental aspect of vertical integration. In the short term, local communities and governments require immediate access to funds that enable them to initiate small-scale development projects. National governments can provide this through community-based funds or national grants. An example of this is Nepal's Local Governance and Community Development Programme, which offers direct financial support to local governments to address infrastructure and social service needs. By supplying these initial funds, local governments can quickly tackle immediate challenges while laying the groundwork for larger, long-term projects.

Over the medium term, public-private partnerships become a crucial financial tool, allowing local governments to work with private sector actors on larger projects, such as infrastructure and energy development. Brazil's Minha Casa Minha Vida, My House-My Life, housing program is an excellent example of how national governments can collaborate with private developers to provide affordable housing, combining

public funding with private sector expertise. In the long run, institutionalizing funding pathways guarantees a steady flow of resources to underdeveloped regions. Mechanisms like the European Union's Cohesion Fund channel sustained investments into areas requiring economic development, bridging the gap between local and national disparities. Vertical integration also relies on harnessing social and cultural dynamics to build trust and cooperation between communities and government authorities.

In the short term, engaging local cultural leaders, such as community elders or religious figures, is essential for promoting dialogue between local communities and government representatives. For instance, in Indonesia, religious leaders have played a key role in promoting sustainable environmental practices, aligning local values with national conservation policies. These leaders act as trusted intermediaries, ensuring that government initiatives are accepted and understood by local populations. As integration advances in the medium term, regular consultations and participatory platforms become vital. Colombia's Participatory Rural Development Program provides a model for fostering social cohesion through ongoing dialogue between local farmers, Indigenous groups, and the national government. By institutionalizing regular policy forums and town hall meetings, local communities are empowered with a voice in decision-making, helping to align local practices with national policies while promoting a shared sense of responsibility.

In the long run, incorporating local knowledge systems into formal governance ensures that vertical integration remains culturally inclusive and sustainable. New Zealand's Te Mana o Te Wai framework exemplifies this approach by integrating Māori water governance practices into national water management policies. This formal acknowledgement of Indigenous Knowledge enhances local governance and ensures that national policies reflect the cultural values of Indigenous Peoples. Achieving effective vertical integration requires developing the necessary skills within local and national governance structures. In the short term, local leaders and government officials should receive training in communication and negotiation skills to advocate for their communities and engage with higher authorities.

In the medium term, local governments need strong policy alignment and administrative coordination skills to ensure their projects support national development goals. Morocco's National Initiative for Human Development illustrates how local governments can be trained to align with national poverty reduction strategies. Developing these skills enables local governments to effectively contribute to national plans, ensuring their local priorities are incorporated into broader policy frameworks.

In the long term, developing monitoring and evaluation capabilities is essential for assessing the effectiveness of vertical integration and making necessary adjustments over time. Kenya's National Integrated Monitoring and Evaluation System is a prime example of how monitoring and evaluation frameworks can be used to monitor development projects at all levels of government, ensuring that goals are achieved and improvements are implemented where needed. Establishing strong monitoring and evaluation systems enables governments to refine their strategies for resource allocation, policy support, and project execution, ensuring that vertical integration remains effective in the long term.

18.2.5.3 Action Three: Institutionalizing capacity-building at all levels to ensure long-term sustainability and impact

To achieve long-term success and sustainable growth, it is essential to institutionalize the capacities developed at local, regional, and national tiers. This involves integrating the skills, knowledge, and systems from capacity-building efforts into formal structures and processes across all levels of governance. Such an approach helps establish resilient institutions capable of adapting to shifting challenges and upholding effective governance practices.

The institutionalization process involves ensuring that local leaders, communities, governments, and stakeholders – including women, Indigenous Peoples, and other marginalized groups – can effectively manage resources, make decisions, and implement projects without relying on external interventions. This includes establishing permanent structures for training, knowledge-sharing, and skill development within local governments, integrating capacity-building into national governance frameworks, and fostering collaboration across sectors. The goal is to ensure that the skills and capacities acquired are retained and become an integral part of governance

Credit: ©UNEP

systems that support sustainable development well into the future.

Institutionalizing capacity-building requires dedicated EF levers to secure sustained support and ongoing improvement. In the short term, local governments and communities require immediate access to resources that can fund rapid-training programmes. For example, Rwanda's National Capacity Building Secretariat allocates funds to train local officials, enabling them to enhance service delivery. By establishing local and national training funds, communities can quickly acquire the skills needed to manage resources, lead development projects, and maintain effective governance systems. This approach ensures that capacity-building begins promptly and yields immediate results.

In the medium term, capacity-building should be incorporated into national development plans and budgets. Ghana's Decentralization Policy Framework is an example of how governments can mandate the inclusion of capacity-building within local governance. By consistently investing in local skills development, governments can ensure that capacity-building becomes an ongoing effort rather than a one-time initiative, integrating it into governance structures. Additionally, national governments should allocate specific funds annually to support local training programmes, helping local authorities enhance their governance capabilities on a continuous basis.

In the long run, establishing sustainable financial mechanisms is key. For instance, India's National Skill Development Fund provides long-term financial support for workforce and capacity development across various sectors. Besides EF levers, SC levers also play a vital role in integrating capacity-building into governance systems. In the short term, local leadership and community participation are crucial for effective governance.

In Kenya and Nepal, for example, Community Forest Associations or Community Forest User Groups bring local communities together to share knowledge on forest governance and management. These platforms not only promote a culture of learning but also ensure that the skills and knowledge shared are rooted in local practices and traditions. Creating similar knowledge-sharing platforms enables local leaders and community members to exchange insights and enhance their collective capacity to manage local governance effectively. Indigenous Knowledge and Local Knowledge systems, especially from Indigenous and rural communities, should be formalized within policy frameworks to ensure

capacity-building remains culturally relevant and widely accepted.

For instance, integrating Indigenous Knowledge systems into the national meteorological system should be considered (Nkuba et al. 2021), as this will involve documenting and validating Indigenous Knowledge systems (Nyadzi et al. 2022; Nkuba et al. 2022). In the long term, incorporating capacity-building into the educational system ensures that future generations are equipped with the skills necessary to address governance challenges effectively. Finland's education system incorporates sustainability, governance, and civic engagement into its national curriculum, preparing students from a young age to become future leaders in governance and sustainable development.

The success of institutionalizing capacity-building relies on developing the right capabilities within local and national governments, as well as within communities. In the short term, targeted training programmes in leadership, governance, and resource management are essential to equip local leaders and officials with the skills they need. Uganda's Local Government Development Programme demonstrates how short-term training can greatly enhance the leadership and governance capabilities of local officials, enabling them to provide better services to their communities. These programmes should be broadly adopted so local leaders can oversee governance and guide their communities towards sustainable development. In the medium term, it is essential to establish institutional knowledge transfer systems that preserve and pass on skills and knowledge within organizations, even as staff members change.

Developing strong monitoring and evaluation capabilities over the long term is crucial. It enables governments to monitor the progress of capacity-building programmes and adjust strategies as needed. Kenya's National Integrated Monitoring and Evaluation System monitors the effects of development initiatives across all levels of government, ensuring that capacity-building aligns with national development objectives. Implementing effective monitoring and evaluation systems enables local and national governments to enhance their capacity-building approaches, thereby supporting sustainable success over time.

18.3 Implication of the solution pathways for a resilient sustainable environment on other systems

The environment system is of underpinning importance to other system transformations in economics and finance (Chapter 14), materials/waste (Chapter 15), energy (Chapter 16) and food (Chapter 17). The environment system should be resilient to climate impacts to support the proposed circularity, as well as the transformations in food and energy systems (IPCC, 2023). Considering the solution pathways outlined here, key points of interaction with food, energy, and circularity systems emerge: land use, preventing biodiversity loss and maintaining soil health, and the widespread implications of transitioning away from fossil fuels alongside the use of various bioenergy technologies and carbon dioxide removal (CDR) technologies.

Of key concern is the use of land, alongside rivers and oceans as a limited natural resource in which to embed energy, food and circularity and the demands on landscape and seascape to deliver a range of ecosystem services as identified in the GEO-7 target seeking scenarios to enable transformations that deliver climate, biodiversity and pollution targets. The widespread deployment of bioenergy has the potential to provide multiple low-carbon energy solutions, including heat, power, and liquid biofuel, with or without associated carbon capture and storage. It serves as a key technology for achieving targets and limiting temperature increase to 1.5°C. However, the land use associated with this demand is significant, although the technical potential of over a billion hectares – once proposed –is considered unrealistic due to sustainability trade-offs related to biodiversity loss, water use, conflicts with land for food, NbS, indirect land-use change, and conservation. The two GEO-7 scenarios both allocate less than one hundred million hectares of land to BECCS and bioenergy, which is substantially less than earlier assessments and is effective in reaching Net Zero by 2050

Halting biodiversity loss is crucial for ensuring future environmental sustainability and achieving global targets. However, the intensification of agricultural systems threatens biodiversity. As discussed in Chapter 17, transforming the food system involves adopting sustainable intensification methods, such as breeding and selecting improved crops and livestock,

alongside a substantial increase in regenerative agriculture practices. Regarding energy systems, the effects of BECCS, bioenergy, and agrivoltaics should be carefully managed to prevent harm to biodiversity (Chapter 16). Additionally, promoting a circular flow of materials and resources can help reduce land degradation. Maintaining material stocks and a circular flow of resources in the economy will also contribute positively to socioeconomic development, while safeguarding Nature and people (Chapter 15). Economic transformation (Chapter 14), must integrate a nature-positive economy approach, recognizing that long-term prosperity depends on the health of ecosystems and policies should prioritize investments in biodiversity, ecosystem restoration, and NbSs to foster a regenerative, resilient, and inclusive economic future, aligned to global targets on biodiversity.

Soil health is key to ensuring stocks of carbon are preserved and soil biodiversity and functioning are enhanced, and it is central to several of the NbS approaches detailed in this chapter. Healthy soils are required for a transformed food system, where regenerative agriculture practices lead to reduced synthetic fertilizer use and improved soil carbon sequestration. For the energy system, linked to circularity, using organic waste to generate energy through anaerobic digestion as part of the circular economy, with residues returned to the soil (Chapters 15, 16), is an important goal for a future resilient environment system. Healthy soils are important for biogeochemical carbon sequestration, and their management remains a significant challenge to deliver multiple benefits of food, biodiversity and energy needs (IPCC, 2019).

Indigenous Knowledge and Local Knowledge Chapeau E

Studies consistently illustrate how Indigenous ontologies, knowledge, values, and ways of being offer pathways for sustainability transformation. Across diverse biocultural regions, Indigenous Knowledge and local knowledge are being deployed through various livelihood strategies and place-based adaptation and mitigation processes to address environmental change (Thornton and Manasfi 2010; Huntington et al. 2017; Orozco-Ramírez et al. 2020). Indigenous Peoples are also contributing to our collective understanding of the dynamic and existential dimensions of global change at local and regional scales (López-Maldonado et al. 2024; Reyes-García et al. 2024). For instance, Indigenous Arctic communities are building detailed observations of sea ice growth, decay and thickness, which are essential for assessing ice mass balance and its implications for climate and human well-being in the region (Ashjian et al. 2010; Krupnik et al. 2010). Also, Indigenous dryland communities in Australia and elsewhere are showing the value of cultural burning practices, honed over millennia, to sustain biodiversity and mitigate disastrous wildfires (Nursey-Bray et al. 2019).

However, GEO-7 is organized by large UN regions or by income-class countries rather than by biocultural regions or livelihood modes. Further, most studies of the role of Indigenous Knowledge and local knowledge in adaptation and sustainability are based at the landscape or cultural region scale. Biocultural and livelihood perspectives illustrate the complexities and contingencies in the relationships between social and ecological change over time at these scales. For example, scientists have long puzzled over the factors that contributed to the so-called collapse of the Maya civilization, particularly the role of climate change (Haug et al. 2003) Studies indicate that climatic change, especially severe drought, played a significant role in the decline of Mayan cities circa 800–1000 A.D. Mayan people endured by adaptively reorganizing to decentralize and de-urbanize in response to these environmental changes (Clayton 2016), while maintaining a mosaic of productive, biodiverse landscapes, such as the milpa system (Ford and Nigh 2010), that still flourish where permitted. To avoid misreading the historical-ecological record and recognizing the underlying causes of unsustainability which can result in ecocide, ethnocide, or other adverse consequences for Indigenous Peoples and their lands, it is essential to have Indigenous perspectives in environmental assessments (Brondízio et al. 2021). Indigenous-led research and social movements can support sustainability transformations, including adaptation to climate change, advancing understanding of the causes, effects and responses to environmental change across the seven UN-recognized sociocultural

Credit: thanyapatm/Envato

regions of Indigenous Peoples. Expanding Indigenous leadership in intergovernmental environmental assessments will enhance Indigenous insights and strategies for sustainability.

Using Indigenous-led results to inform future scenarios of stewardship and adaptation at meaningful biocultural scales can lead to important breakthroughs. For example, a recent study using data on soils in 703 tribal land areas in the United States, reveals how Indigenous Knowledge can shape sustainable agricultural futures (Chesnais et al. 2024). The analysis makes clear the high potential for Indigenous regenerative agroecological practices to transform food systems, addressing global environmental crises and local issues of sustainability, food sovereignty, biocultural diversity and health. The study also demonstrates how the benefits of Indigenous Knowledge are obscured by data biases. The findings reinforce the need to amplify Indigenous perspectives and leadership roles in the conceptualization, collection, use and management of data on human-environmental systems, including medicinal plants to avoid biases that lead to suboptimal solutions, environmental harms or other injustices. More equitable processes for developing transformation pathways are already being considered or implemented in select biocultural regions with Indigenous inhabitants to strengthen their rights and stewardship capacities (Turner and Spalding 2013; Chesnais 2022; Forest Peoples Programme 2024). International governance organizations can assist with this by partnering with Indigenous Peoples to address environmental crises and just sustainability transitions in multicentric and bioculturally integrated ways (Indigenous Summit Just Transition 2024; Muthukrishnan and Datta 2024; IK & LK Dialogues 2025).

Chapter summary

Credit: Dmitry_Rukhlenko/Envato

Countries at different stages of economic development face distinct challenges and opportunities in the transformation towards sustainability goals.

High-income countries (HICs) are well-positioned to influence multilevel and multilateral governance, macroeconomic and fiscal policy to support sustainable financing in the global economic transition *(well established)*. This involves strengthening international tax norms, advancing the effectiveness of the development bank system, operationalizing the Fund for responding to Loss and Damage (FRLD), debt relief, and stimulating the development of green technologies {19.3.1}.

By investing in green technologies and sectors, HICs can diversify their economies, reduce resource dependency, and generate employment opportunities in sustainable industries. With access to advanced technologies, HICs are well-positioned to develop and implement effective strategies for resource management and waste reduction *(well established)* {19.4.1}. Growing renewable energy deployment, supported by policy frameworks and offering socio-economic benefits like job creation, illustrates this potential *(established but incomplete)* {19.5.1}.

Beyond renewable energy deployment, electrifying transport and heating, supported by financial markets capable of mobilizing substantial private investment, and effective policy frameworks that provide robust regulatory support, will be critical in HICs *(well established)*. However, challenges persist in managing the socioeconomic impacts of phasing out fossil fuels. Coal-dependent communities, in particular, will require just-transition measures and comprehensive social programmes. Additionally, renewable energy infrastructure development may raise environmental concerns, including the potential degradation of protected areas, key biodiversity zones, and wilderness regions from onshore and offshore wind, hydropower, and solar photovoltaic installations, though these impacts are generally limited. Nevertheless, these developments can contribute to broader environmental issues, including

biodiversity loss, air pollution, and land degradation *(established but incomplete)* {19.5.1}.

Transforming the food system in HICs will require promoting sustainable agricultural practices. This includes pursuing organic farming, improving livestock productivity, and promoting afforestation *(established but incomplete)* {19.6.1}.

Imposing carbon tariffs in HICs can prevent producers from shifting polluting operations to countries with weaker environmental standards. By targeting carbon-intensive imports, such as steel and cement, these tariffs can help overcome the limitations of production-based, or polluter-pays, emissions accounting, which can falsely suggest environmental progress while potentially increasing overall global emissions *(established but incomplete)*. As of this writing, no carbon tariff programmes have yet been fully implemented {19.7.1}.

On the demand side, HICs can reduce consumption and improve resource efficiency *(well established)*. As major consumers of global materials, doing so offers considerable economic savings by reducing raw material demand, energy use, and waste management costs. By leading in resource efficiency and environmental stewardship, HICs can shape international policies and practices {19.4.1}.

Changing consumer behaviour and preferences around energy and food consumption can yield significant benefits *(well established)*. Policy incentives and infrastructure investments can promote energy-efficient technologies and discourage carbon-intensive lifestyles. Both market-based and voluntary approaches are required to encourage sustainable diets. Minimizing food waste, encouraging dietary changes and promoting regional food products can enhance self-sufficiency and reduce food insecurity {19.6.1, 19.7.1}.

Industrializing and urbanizing middle-income countries (MICs) need to ramp up investments in sustainable infrastructure to address significant service gaps, particularly in housing and transportation *(well established)*. Strategic public investments can support the development of durable, resource-efficient infrastructure. This includes adaptable and sustainable residential and commercial buildings, integrated public transportation networks, and cities designed for active mobility. Incorporating secondary materials into manufacturing and construction also demands substantial investments in waste management and resource recovery infrastructure. Making economies more circular and mitigating associated risks will require institutional reforms and innovation in resource governance and material management strategies {19.3.2, 19.4.2}.

Proactive industrial and innovation policies tailored to local contexts can support the development of green technologies *(established but incomplete)*. MICs can adopt sustainable industrial practices from the outset, framing the transition as a growth opportunity. Realizing benefits from green technologies will require a sustained focus on human capital and capacity building {19.4.2}.

Careful planning for coal phase out, fossil fuel subsidy reform, and renewable energy development will be critical for MICs in the energy transition *(well established)*. Addressing existing fossil fuel dependencies and infrastructure challenges, particularly in rapidly urbanizing areas, remains a key concern *(established but incomplete)*. Integrated policymaking can accelerate the adoption of renewable energy while mitigating environmental impacts, such as climate change and air pollution. With sufficient human and economic resources, the MIC countries have the opportunity to leapfrog to a green economy by promoting clean technology and removing fossil fuel subsidies {19.5.2, 19.7.2}.

Incorporating environmental and health externalities in national development planning could support sustainable development pathways *(established but incomplete)*. Middle-income countries face the challenge of striking a balance between economic development and environmental protection. Raising public awareness of pollution and the related health risks can help to create public demand for more decisive action against pollution. Finally, all countries need to develop legislation and enforcement mechanisms that guarantee access to justice for all citizens who bear the brunt of pollution's consequences {19.7.2}.

For low- and middle-income countries, ensuring effective waste management and resource recovery systems, especially in fast-growing cities, is a key priority *(well established)*. The informal sector plays a significant role in repair, reuse and resale, offering valuable opportunities. However, more research is needed to understand and realize this potential fully {19.4.2} {19.4.3}.

Foreign direct investment and targeted renewable energy subsidies, alongside policies addressing

Credit: bilanol/Envato

institutional barriers, are crucial to overcome resource constraints and enable energy transition in low-income countries (LICs) *(established but incomplete)*. While LICs hold substantial renewable energy potential, financial barriers, especially high upfront costs, limit the adoption of renewable energy and energy-efficient technologies. While renewable energy subsidies can support environmental goals, it will be critical to balance economic development with energy efficiency as per capita energy use continues to rise. Maintaining this balance requires an enabling environment that attracts investment in renewable projects while supporting a gradual shift from fossil fuels to cleaner energy sources {19.5.3}.

In LICs, sustainable agricultural approaches such as agroecology and agroforestry can help restore and nurture the natural capital of ecosystem services, sustain yields, protect biodiversity and reduce pollution from chemical fertilizers and pesticides *(well established)*. Achieving this will require government investment in farmer training and support for sustainable production methods, while discouraging unsustainable practices {19.6.3} {19.7.3}.

International action and cooperation in science, technology, innovation and sustainable financing are highly beneficial. In both middle- and low-income countries, building capacity and supporting technology transfer are essential for driving system transformation *(well established)*. Strengthening local research capacities and developing a skilled workforce will reap long-term benefits. Participation in international green innovation initiatives can facilitate the transfer of technology, knowledge and financial resources, while strong local capabilities can ensure successful integration into local contexts {19.4.3, 19.7.3}.

19.1 Introduction

Countries at different stages of development face distinct challenges and opportunities in their transition towards sustainability goals. This chapter examines solution pathways tailored to varying economic contexts, highlighting examples of best practice with key challenges and opportunities. Recognizing that one size does not fit all, this chapter emphasizes the importance of context-specific approaches to support transformative change.

In designing an effective response to the environmental crises, it is essential to recognize the diverse contexts of countries, ranging in economic development, environmental health, and resource endowments, that shape the distinct outlooks of nations across the globe. While some countries grapple with limited resources and fragile ecosystems, others boast strong economies and relatively healthy environments. Tailoring strategies to these differences is key to leveraging each country's strengths while addressing their specific challenges.

19.2 Country groupings

The focus throughout this chapter is on three economic country groupings adapted from the World Bank country classification system. The World Bank classifies countries into four per capita income bands: low, lower-middle, upper-middle, and high-income countries (World Bank 2023a). However, for the purposes of this chapter and to simplify the solution pathways by system and country, three country-economic groups are defined: High-income, industrializing and urbanizing middle-income, and financially constrained low-income countries. Additional details about the countries in each group are provided in Appendix 19.1 (**Figure 19.1**), including information on population density and trade status to inform the analysis.

High-income countries (HICs) are those with a gross national income (GNI) per capita exceeding US$13,845 (World Bank 2023a). For these nations, the transformation involves strengthening existing sustainability efforts, managing and maintaining infrastructure, encouraging responsible consumption, and addressing potential environmental impacts they cause beyond their borders.

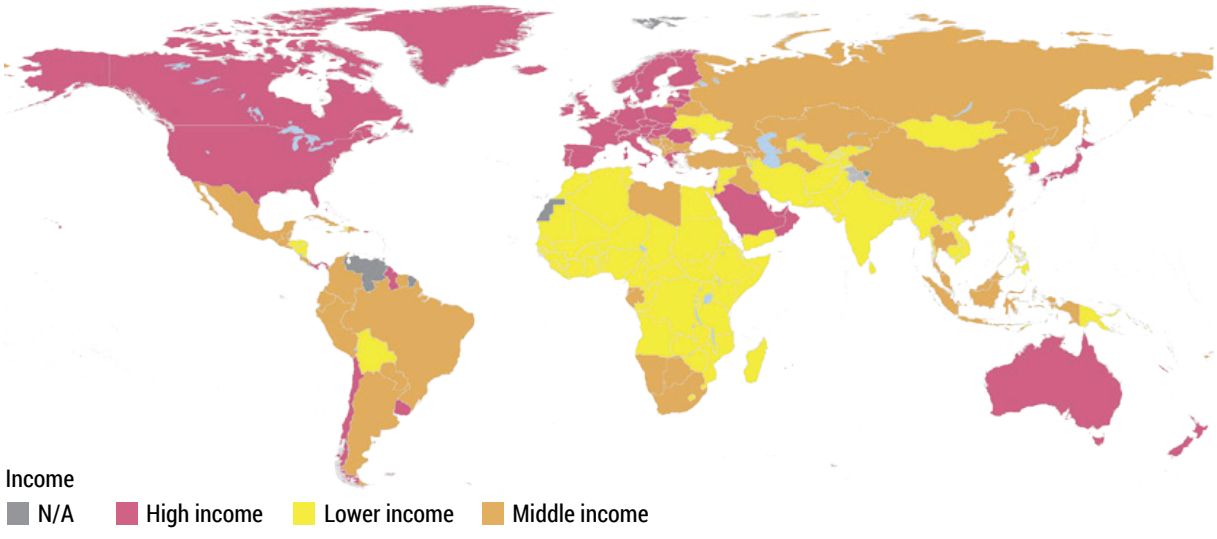
Industrializing and urbanizing middle-income countries (MICs) are classified as having a GNI per capita between US$4,466 and US$13,845 (World Bank 2023a). In this group, countries experience rapid urbanization, a quick increase in energy use, and higher consumption of animal protein. These

Credit: BGStock72/Envato

transformations present a unique opportunity to shape urban planning, energy infrastructure, and economic growth in a sustainable manner.

Financially constrained low-income countries (LICs) are those with a GNI per capita below US$4,466 (World Bank 2023a). These countries often possess abundant natural resources but have limited economic capacity, facing unique challenges in managing their transitions. For this group of countries, it is essential to balance the exploitation of natural resources for economic growth with sustainable practices.

While other grouping approaches and country classifications exist, such as the International Monetary Fund's classification of advanced, emerging, and developing economies, this analysis recognizes the financial capacity of different countries to ensure that proposed solutions are realistic. This does not suggest a "one-size-fits-all" solution per country group but recognizes that solution pathways can be contextualized based on other sociocultural and political characteristics of countries. Chapter 20 further supports this analysis by providing solution pathways from a regional country perspective to capture nuanced development features.



This chapter explores the diverse nature of the three economic groups and interprets system transformations across different stages of economic development. Selected case studies highlight best practices to support solution pathways within each group. Where

Credit: dotshock/Envato

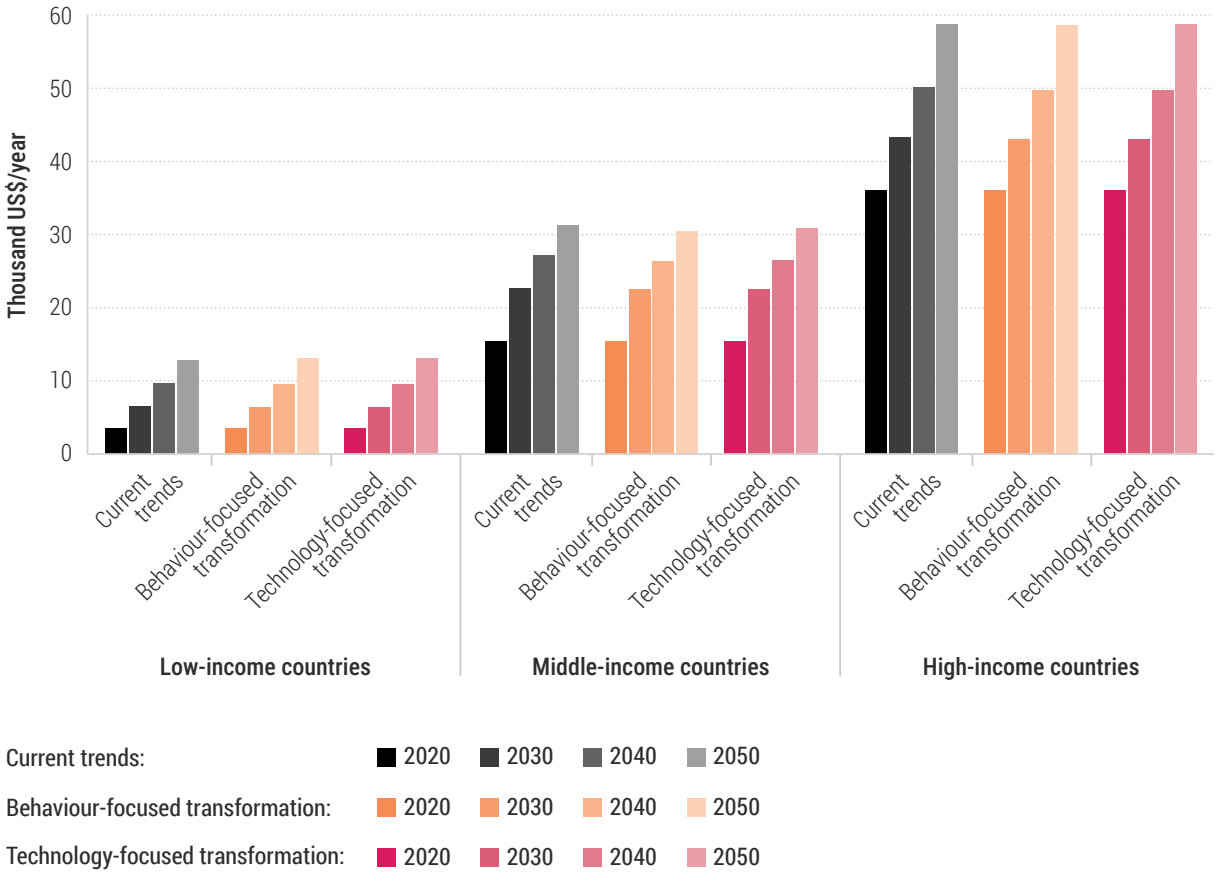
relevant, results from the two modelled scenarios are discussed. More details about these scenarios are available in Chapter 11. In short, Chapter 11's Technology-focused Transformation Scenario relies on technological development, particularly aimed at a green economy, while the Behaviour-focused Transformation Scenario involves societal changes in values, beliefs, and norms, moving away from dominant cycles of consumerism (11.2). The model outputs for these two scenarios across the five systems (Economic, Materials/Waste, Energy, Food, and Environment) are also presented, broken down by country grouping (High-, Middle-, and Low-income).

Figure 19.1: World map with adapted country groupings defined according to the World Bank's economic classification

Source: World Bank 2022

19.3 Transformation of economic Systems

The current economic paradigm, along with population growth, is pushing countries further away from sustainability. It is widely recognized that economic growth alone cannot attain environmental sustainability (Cumming and von Cramon-Taubadel 2018). Projections of GDP per capita are expected to increase based on current trends and in the two transformation scenarios, as shown in **Figure 19.2**. However, high-, middle-, and low-income countries display distinct economic and consumption patterns and opportunities. These differences influence how they use natural resources and respond to population growth, requiring tailored approaches during the transition to sustainable governance and finance.



19.3.1 High-income countries: Steering sustainable financing

Countries with high incomes have higher material consumption and waste per capita (United Nations 2023a). The increasing use of natural resources leads to greater environmental impacts, which are often transferred to other nations through imported products (Cumming and von Cramon-Taubadel 2018).

HICs can steer multilevel and multilateral governance, as well as macroeconomic and fiscal policies, towards sustainable financing. This includes efforts to strengthen international tax standards, particularly for digitalized and globalized businesses, as well as to reassess the role of development banks. Key initiatives involve operationalizing the Fund for responding to Loss and Damage (FRLD), facilitating debt relief, reforming the international debt resolution framework, and addressing tensions over green subsidies through revised trade rules (United Nations 2023a).

While sustainable finance is expanding rapidly, most resources are still concentrated in HICs, which control 80 per cent of global finance. However, less than 3 per cent of sustainable investments are directed to low-income countries. HICs play a key role in removing barriers

Figure 19.2: GDP per capita (2010 US$) across the three country groups

Note: These projections take into account the policy costs for the transformation pathways as well as climate damages.

Credit: SouthworksStock/Envato

that restrict financing for sustainable development in low-income regions (Organisation for Economic Cooperation and Development [OECD] 2022) (**Box 19.1**).

Within their borders, HICs can revise policies and regulations to better align private sector profits with sustainability goals (United Nations 2023b). Encouraging businesses to adopt resource recovery initiatives and resource circularity is essential. Moving toward a less resource-intensive system of production and consumption, while developing workforce skills for low-carbon technologies, will facilitate this transition (World Bank and International Monetary Fund 2014). International cooperation in science, technology, and innovation is vital for sustainability (Stamm 2023). Several key donor countries have committed at least 40 per cent of their development aid to green innovation (OECD 2019). Developing human capital and transferring knowledge are crucial for integrating sustainable technologies into local contexts, driving structural change, and ensuring lasting impact (Hansen et al. 2018).

Countries with high incomes can move beyond traditional GDP growth targets and metrics, exploring alternatives like "post-growth" and "degrowth." By redefining economic narratives, these nations can adopt a more comprehensive view of socio-economic progress (European Parliamentary Research Service 2023). Additionally, encouraging behavioural and lifestyle shifts, partly motivated by awareness of climate and ecological crises, can help decrease energy demand and resource use in HICs.

Making sure that sustainable options are accessible and practical will be essential for encouraging lasting change (OECD 2022).

Box 19.1: Case study: France's development cooperation profile

France ranks highly among the main providers of official development assistance (ODA), with a strong emphasis on Africa. The donor country allocated US$15.9 billion in ODA in 2022, which amounts to 0.56 per cent of its GNI. Sixty-six per cent of its aid goes towards supporting the environment and the Rio Conventions, while 56 per cent focuses on climate change (OECD 2024).

19.3.2 Balancing economic growth and environmental impact in middle-Income countries

In MICs, rapid economic growth results in increased consumption and spending needs relative to GDP (McKinsey and Company 2022). These countries are also catching up to HICs in energy demand. Simultaneously, rising living standards and rapid urbanization present significant environmental challenges.

The main challenge for MICs is to create a growth model that balances economic development with energy saving and environmental protection (Li and Lin 2019). Using existing technologies and innovations can support sustainable development while reducing the risks of resource depletion and environmental degradation.

MICs also face pressing infrastructure challenges. As these countries experience urban growth, they need to increase investments in infrastructure to fill existing gaps and replace ageing, polluting systems. Public-private partnerships can help fund infrastructure projects when suitable. Additionally, investing in resilient infrastructure as a climate change adaptation strategy offers a green growth opportunity. These investments can deliver high economic returns by minimizing long-term climate-related damages. For MICs, every dollar invested in adaptation can generate up to four dollars in economic benefits (Global Commission on Adaptation 2019).

Other essential measures for MICs involve planning for coal phase-outs, reforming and gradually eliminating fossil fuel subsidies, promoting renewable energy sources, encouraging circular economy practices, and enhancing waste management, sustainable agriculture, and land use (Deutsche Gesellschaft für Internationale Zusammenarbeit [GIZ] 2021).

Moreover, proactive policies in the industry and innovation can accelerate the adoption of green technologies. Framing the transition as a development opportunity that emphasizes quality is crucial (Rodrik and Stiglitz 2024). Investing in capacity building, especially in human capital, will help create pathways to sustainable growth (**Box 19.2**).

19.3.3 Aligning financial flows with sustainability goals in low-Income countries

Countries with low incomes experience significant financial limitations and often depend heavily on ecosystems for their livelihoods (Cumming and von Cramon-Taubadel 2018). This group of countries is disproportionately impacted by ecological crises, and their scarce financial and human resources restrict their ability to invest in sustainable changes (United Nations 2023b). Consequently, LICs rely more on foreign technology, knowledge, and financial aid compared to other nations.

Investment in sustainable activities continues to be constrained in LICs because of the high risks from conflict, natural disasters, and disease outbreaks. Additionally, there are few sustainable finance options for firms in LICs or small and medium-sized enterprises (SMEs). These businesses frequently lack the necessary expertise and capital to obtain green loans or to engage in green bond markets (Global Sustainable Finance Working Group 2022).

Innovative options like concessional financing can speed up achievement of development objectives. Debt-for-nature swaps present a promising strategy, providing both sovereign debt relief and opportunities for environmental conservation (Losos, Pfaff and Pimm 2024). This approach is especially relevant where limited fiscal resources restrict environmental

Box 19.2: Sustainable Banking and Finance Network

The Sustainable Banking and Finance Network (SBFN) is a global initiative focused on building sustainable finance capabilities. Launched in 2012, it is a voluntary community of financial sector regulators, central banks, ministries, and industry associations from emerging markets. SBFN encourages knowledge exchange and capacity building to help align sustainable finance with national development goals. These efforts enhance risk management and support increased capital flows directed at environmental and social objectives. As of August 2024, SBFN includes 96 member institutions from 72 countries, covering both middle and low-income nations (SBFN 2024).

investments. Additionally, LICs can enhance their role in international arenas to build capacity in sustainable finance. Governments, financial regulators, and other stakeholders should participate in global platforms to better coordinate financial flows with sustainability targets.

Finally, it is crucial to address power dynamics between governments and extractive industries. In many LICs, sectors like mining and industrial fishing hold significant sway over environmental policies due to lobbying efforts and their economic contributions to the national economy (Teixidó-Figueras et al. 2016; Childs 2020). Tackling these deeply rooted power dynamics is essential for driving meaningful systemic change.

19.4 Transformation towards circularity and sustainable materials management

Since the 1970s, global living standards have significantly improved, but this progress has also led to notable increases in material demand, waste generation, and emissions. From 1970 to 2024, worldwide material extraction, including biomass, fossil fuels, metal ores, and non-metallic minerals, rose from 30 billion tons (8.4 tons per person) to 106 billion tons (13.2 tons per person) (United Nations Environment Programme [UNEP] 2024).

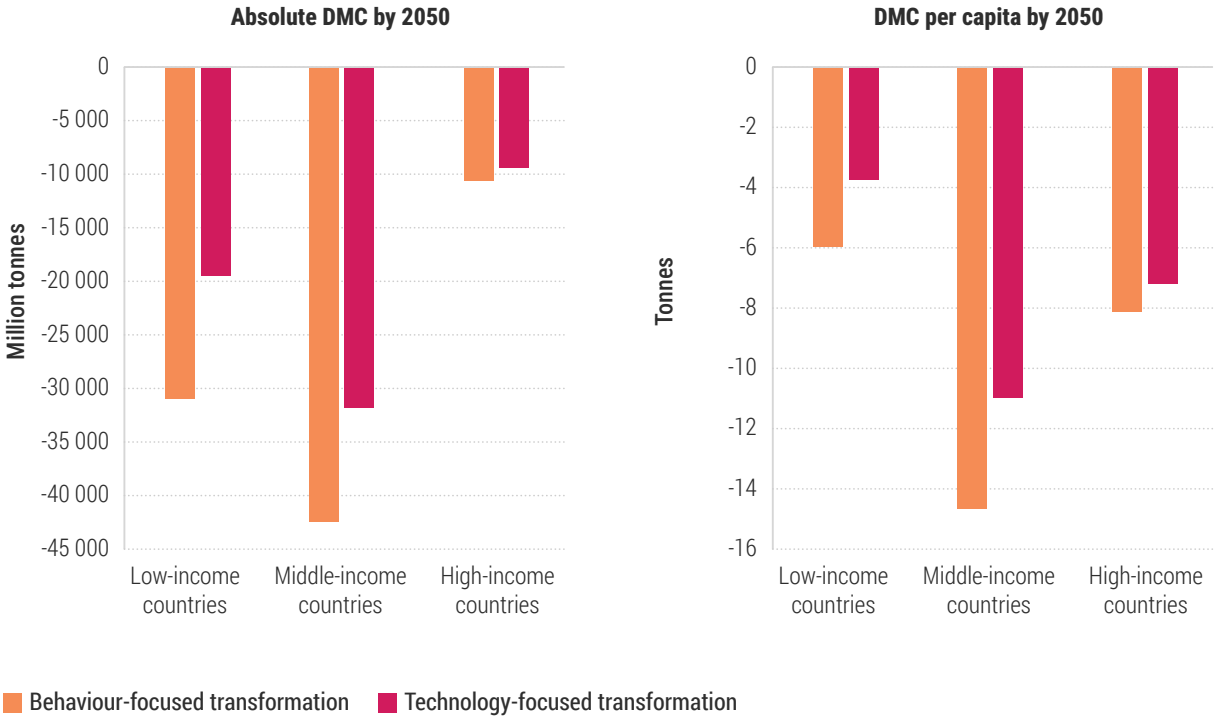
Material extraction accounts for 50 per cent of climate change impacts, 90 per cent of biodiversity loss and water scarcity, and 30 per cent of air and water pollution (UNEP 2024). While middle-income countries now represent 60 per cent of global material consumption, high-income nations still use materials at a rate six times greater than low-income countries (Schandl et al. 2018).

The Sustainable Development Goals (SDGs) emphasize the importance of resource efficiency and sustainable materials management. A circular economy presents a practical solution by reducing resource consumption through maintaining the value of materials and by increasing the lifespan of infrastructure and products (Geissdoerfer et al. 2017). Nonetheless, as of 2024, only 7.5 per cent of material demand is met through secondary sources (UNEP 2024), highlighting significant potential for further advancements.

There are many economically appealing opportunities for resource efficiency and circular economy measures in the housing, mobility, food, and energy sectors in the short term. Over the long term, investing in circularity and conserving natural resources proves to be the most economically advantageous approach, as current trends **(Figure 19.3)** indicate.

If the global economy stays on its current trajectory, material consumption is expected to increase from 106 billion tons in 2024 to 165 billion tons by 2050. However, both the Technology-focused Transformation Scenario and the Behaviour-focused Transformation Scenario, explained in Chapter 11, could significantly lower global material demand. The technology-focused approach would cut material use to 104 billion tons, about 60 billion tons less than the baseline, while the behaviour-focused approach could bring it down to 81 billion tons, a reduction of 84 billion tons.

Choosing either of the two transformation scenarios would have the most significant impact on domestic material consumption, a key indicator in material flow accounting, in MICs and the least impact in HICs **(Figure 19.3)**.



Approximately half of the projected decrease in material demand is expected to happen in middle-income countries, which are also likely to experience the largest decline in per capita material availability. This could limit their capacity to invest in infrastructure crucial for reaching SDG goals focused on people and prosperity.

A similar challenge applies to low-income countries, where there is an even greater need for basic infrastructure, such as buildings, transportation, communication, energy, and water and sanitation systems. These factors emphasize the importance of balancing environmental goals with socio-economic development priorities. Achieving this balance will require a coordinated global effort to facilitate a fair transition that ensures no one is left behind.

19.4.1 Unlocking technological and economic leadership through circularity in high-income countries

Countries with high incomes maintain a high per capita material footprint, indicating both high living standards and significant environmental impacts. Historically,

Figure 19.3: Reduction in Domestic Material Consumption (DMC) by 2050 in the behaviour-focused and technology-focused transformation pathways compared to the baseline, absolute values and per capita

these nations depended heavily on material imports to support their economies (Schandl et al. 2018). Over the past decade, this pattern has evolved. Some HICs, especially those with low population densities, abundant natural resources, and economies rooted in agriculture and mining, such as Australia, Canada, and, to a lesser extent, the United States of America, have transitioned into net exporters of biomass, fossil fuels, and metal ores. Meanwhile, HICs in Europe and Asia, such as Japan and the Republic of Korea, continue to depend on imported materials to maintain their economic functions.

Shifting toward enhanced resource efficiency, waste reduction, and emission management requires deliberate and strategic policymaking (Hatfield-Dodds et al. 2017). Countries with high incomes that rely on importing materials have implemented proactive policies to enhance resource use efficiency, reduce waste, and promote circular economy practices, aiming to strengthen their economic resilience (Haas et al. 2015). Conversely, resource-rich HICs with vast fossil fuel and mineral deposits often prioritize economic gains over sustainable production and consumption, exhibiting a reluctance to implement environmental sustainability policies.

HICs draw advantages through access to cutting-edge technologies, allowing them to develop and apply efficient resource management strategies. Advances in renewable energy, recycling, and materials science can significantly reduce resource consumption and waste (Roy and Tarafdar 2022). By investing in green tech and sustainable industries, these countries can diversify their economies, reduce the dominance of resource-intensive sectors, and create employment opportunities within sustainable fields.

This approach depends on innovative business models (Geissdoerfer et al. 2018) and on training both new and existing workers to acquire the skills needed for a circular economy (Buyukyazici and Quatraro 2025). It also involves supporting women's entrepreneurship in recycling and waste management sectors and ensuring women have access to training and resources (Crespo-Rosas and Franco-Garcia 2023). Regarding per capita material consumption and the significant share of global resource use, it is essential for HICs to reduce their material demand, thereby creating space for middle- and low-income countries to develop their infrastructure (Hickel 2021). Efficient resource use reduces costs, including those for raw materials, energy, and waste management, and helps HICs lead in global sustainability initiatives (Schandl et al. 2016).

Credit: vectorfusionart/Envato

By setting strong resource and environmental standards and leveraging their experience with circular economy policies in Europe, Japan, and China (McDowall et al. 2017), HICs can influence international policymaking and promote sustainable practices worldwide.

19.4.2 Building resilient economies through circular infrastructure in middle-income countries

Middle-income countries stand at a crucial juncture, confronting both challenges and opportunities as they move toward a future characterized by high resource efficiency, low waste, and a circular economy. These countries have higher material demand than both low- and high-income countries, primarily due to rapid economic growth and heavy reliance on imports (Wang et al. 2022a). However, their per capita material consumption stays comparatively modest, and they need to meet urgent infrastructure needs to support expanding populations and achieve the SDGs.

The construction of new buildings and infrastructure, especially for housing and transportation, presents a unique opportunity for MICs. Large-scale public investments can be strategically focused on creating resilient and resource-efficient infrastructure (Hebb 2019). This includes opting for sustainable architecture in and commercial structures, extensive public transit systems, and urban designs that encourage active mobility. These investments not only promote sustainable development but also support lower-income communities by offering shared mobility options and enhancing the quality of life in cities. As MICs experience rapid industrialization and urbanization, they are well-positioned to incorporate circular economy practices into their infrastructure, potentially setting an example in environmental responsibility and economic resilience.

The transition of middle-income countries is characterized by a surge in material demand, resulting in higher waste generation across various categories and a shift from biomass to predominantly non-renewable resources (Schandl et al. 2016). Governments and industries need to invest significantly in waste management and resource recovery infrastructure to meet rising demand while reducing landfill waste by incorporating secondary materials into manufacturing and construction.

Effectively managing this transition and reducing related risks will likely require institutional reforms and innovations in resource governance and sustainable material management strategies (Lockwood et al. 2010). Scenario analysis indicates an alternative development path that departs from the conventional model of industrialization followed by environmental remediation. Instead, it favours a trajectory that emphasizes sustainable industrial practices from the outset (Gerst, Raskin and Rockström 2014).

For countries with high population density, it is crucial to secure access to affordable materials on the global

market. These nations can enhance their economic resilience by strengthening recycling and resource recovery efforts. Meanwhile, countries with lower population densities in this group should implement proactive environmental policies and follow best practices, guiding extractive industries toward practices and outcomes that support sustainability and minimize environmental impact. (Measham, Fleming and Schandl 2015).

19.4.3 Harnessing local potential and global support for circular economies in low-income countries

Since the 1970s, LICs have experienced little benefit from the growing global demand for materials (UNEP 2019[a]). Their per capita material supply has remained stagnant, reflecting a lack of essential services such as energy, transport, water, sewerage, and waste management infrastructure. These countries often struggle with weak institutional frameworks and lack effective governance over their natural resources, which hampers their economic development.

To overcome these issues, low-income countries will need substantial support from high- and middle-income nations, especially in developing environmentally sustainable infrastructure for housing, transportation, food, and energy. A crucial focus is on establishing effective waste management and resource recovery, particularly in rapidly expanding cities (Aleluia and Ferrão 2016) (**Box 19.3**). Enhancing living conditions remains a key objective,which suggests that, even within a circular economy approach, their demand for materials will likely increase considerably until the mid-21st century.

Densely populated countries in this group face compounded challenges. They need to expand infrastructure to support their large populations amid ongoing urbanization. Ensuring access to essentials like food, shelter, and utilities is uncertain and requires substantial investments and international aid. (Ahmed, Mahmud and Acet 2022).

On the other hand, countries with low population density in this group, though rich in natural resources, encounter development issues tied to an extractive economy (Vilaysouk, Schandl and Murakami 2019). Nevertheless, they could capitalize on their natural resource wealth, especially if these resources are managed well and for the broader benefit of their populations.

The informal sector offers a valuable area for exploration, as it is a common hub for repair, reuse, and resale activities. However, there is limited data on these practices, which are crucial for fostering circularity. More research is needed to understand the potential of such activities. Promoting and strengthening these activities can generate more value for these countries and bring additional benefits to the workers engaged in them.

19.5 Transformation of energy systems

This section examines the unique challenges and opportunities involved in transforming energy systems across three economic groups. It explores how specific characteristics of each group influence key components of the energy system, including sources, conversion processes, system integration, end-use needs, the roles of various end users including

Box 19.3: Circular economy approaches for the electronics sector in Nigeria

Nigeria lacks sufficient recycling infrastructure to handle e-waste, relying heavily on the informal sector for metal recovery. About 100,000 people are engaged in informal e-waste processing, handling around half a million tons of discarded appliances each year (UNEP 2019b). Although laws exist to ban e-waste imports and promote responsible management practices, weak enforcement remains a major obstacle (GIZ 2021). In 2019, the Nigerian government, with support from the Global Environment Facility and UNEP, launched a US$15 million initiative to develop a circular electronics system. This effort united government, private sector, and civil society to foster a financially sustainable circular economy for electronics. The approach aims to safeguard the environment while creating safer jobs for informal workers. Key steps include implementing Extended Producer Responsibility legislation and encouraging regional and global sharing of knowledge on circular economy practices.

women, and policy frameworks. A range of economic, environmental, resource, and technological indicators is evaluated (Clarke et al. 2022). Whenever relevant, the discussion also considers public acceptance and health impacts, along with institutional aspects, including political feasibility and governance capacity.

19.5.1 Managing the energy transition in high-income countries

Countries with high incomes show different levels of renewable energy adoption. In Europe, renewables make up 19 per cent of the total energy supply, supported by policies and investments (Roth et al. 2022; International Energy Agency [IEA] 2023a). In contrast, HICs in Asia and the Pacific and North America have lower shares, around 11 per cent (IEA 2023a). Though most HICs actively incorporate renewables and electrify sectors like transportation and heating (Lin and Okoye 2023), some HICs in the Middle East have renewable shares below 1 per cent, heavily depending on fossil fuels (Adun, Ishaku and Ogungbemi 2022; IEA 2023a; International Renewable Energy Agency [IRENA] 2020).

Electricity generation from renewables also varies: Europe leads with 40 per cent, followed by Asia and the Pacific and North America at 27 per cent (IEA 2023a). The Gulf Cooperation Council (GCC) countries are well-positioned for renewable energy growth, benefiting from significant private investment aligned with national targets. However, additional policy measures are needed to improve financing for renewables (Krupa, Poudineh and Harvey 2019).

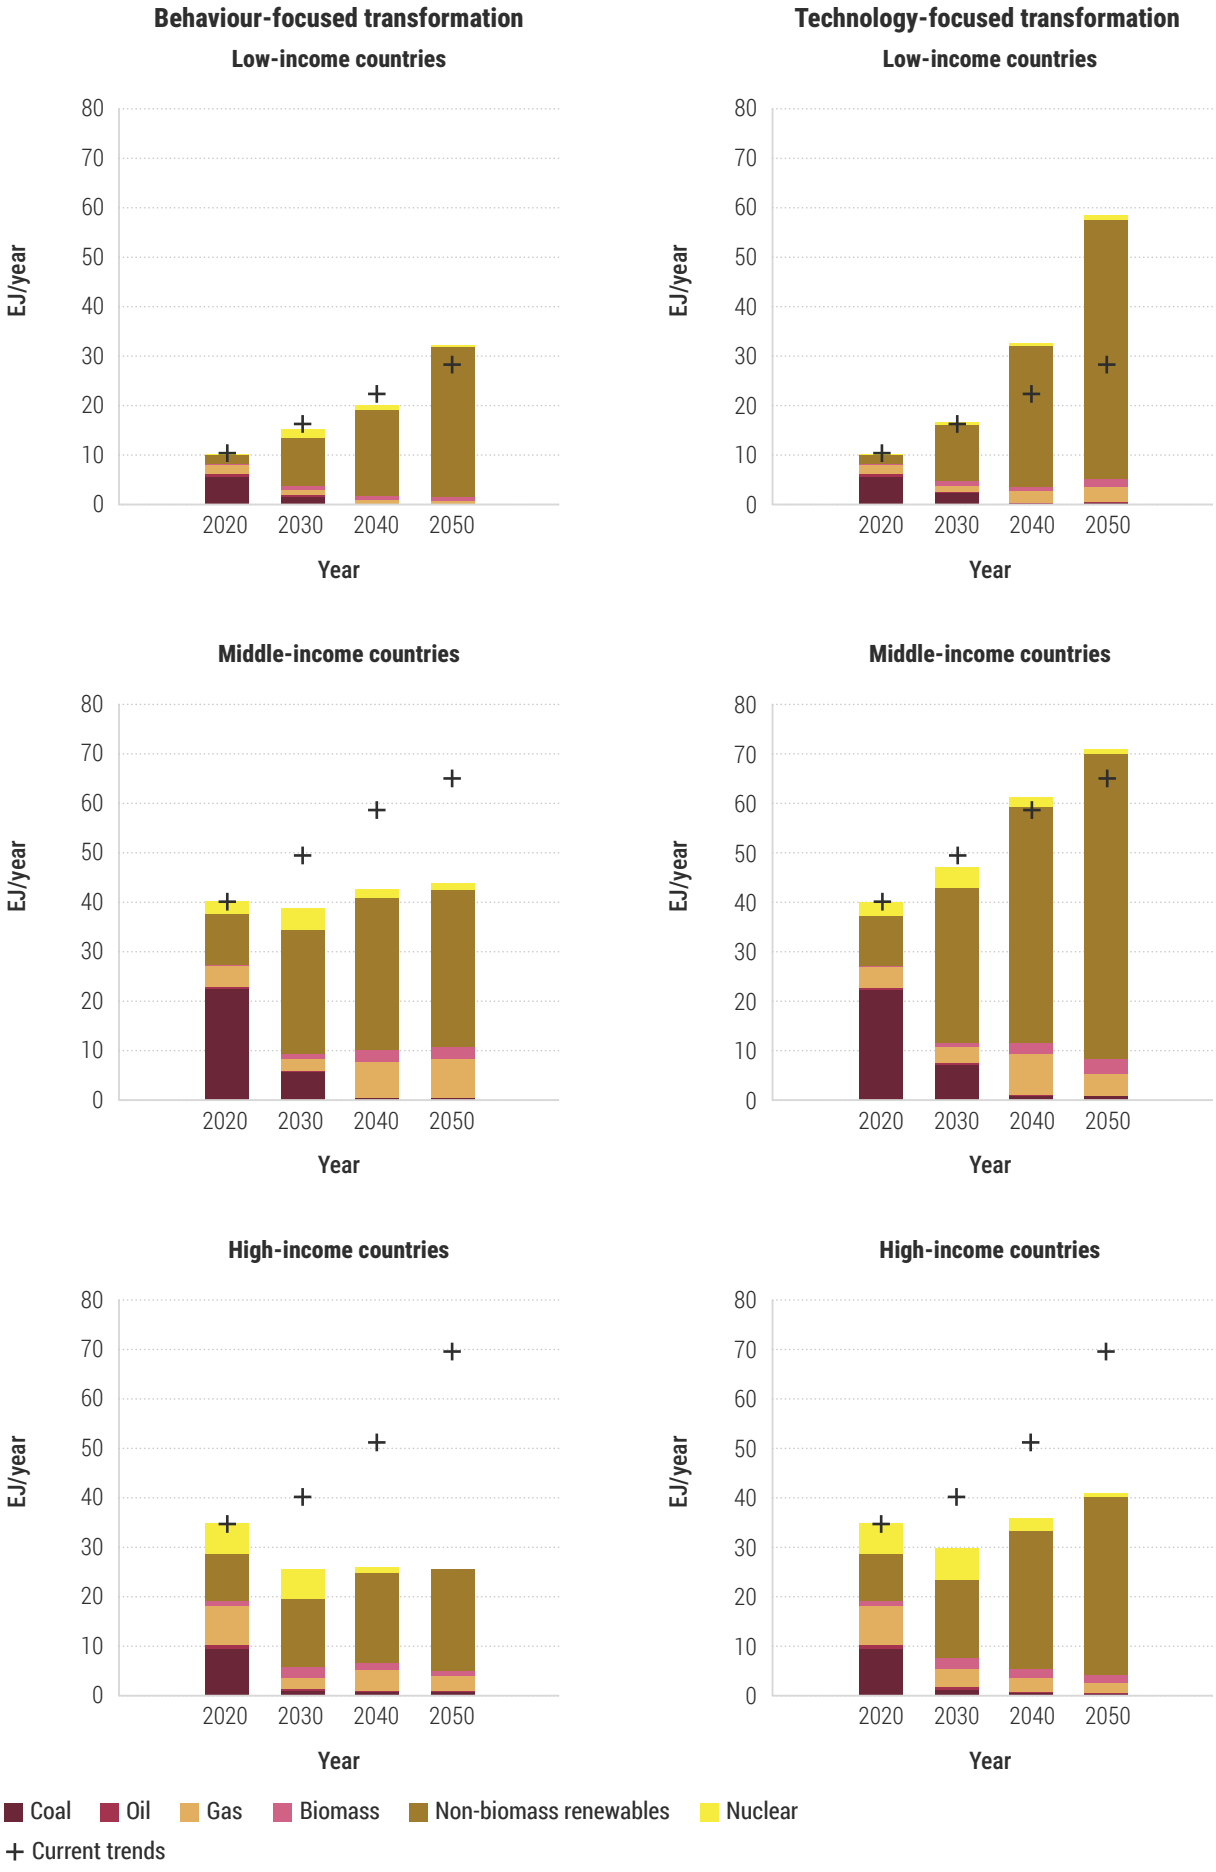
The transition to sustainable energy systems in HICs involves key components. Initially, expanding renewable energy capacity depends on strong regulatory policies and higher investment returns (Dalei and Joshi 2023). Countries that remain reliant on fossil fuels need to diversify their economies to support this transition. Solar and wind power are particularly promising options for meeting growing energy needs (Zhang et al. 2017). Expanding renewable energy capacity provides socio-economic benefits, including job creation in the renewable sector (Azarpour et al. 2022). Some countries are exploring green hydrogen as a low-emission alternative to natural gas. However, its application remains limited (for domestic heating) and is currently not cost-competitive. (Hristescu 2022; IEA 2023a).

Figure 19.4 shows future power generation through two transformation scenarios, either Technology-focused or Behaviour-focused (see Chapter 11). Both scenarios assume that non-biomass renewables will lead electricity production in HICs by 2050. However, the Behaviour-focused Scenario anticipates lower overall electricity demand due to lifestyle changes and increased efficiencies.

The transition in HICs also projects a decrease in final energy demand per person by 2050, as shown in **Figure 19.5**. This decline is especially significant in the scenario focused on behavioural changes, mainly due to lower demand in residential, transportation, and industrial sectors. These projections emphasize the importance of energy-efficient technologies and sustainable policies (De Angelo et al. 2021). However, even with the financial means to adopt sustainable technologies, carbon-intensive lifestyles still pose a challenge to lowering demand-side emissions. Robust policy incentives and infrastructure investments are crucial for achieving the targeted emission reductions (Mi et al. 2020; Rajput et al. 2023; Starr et al. 2023; IEA 2023b).

The energy transition in HICs presents both challenges and opportunities. Phasing out fossil fuels, particularly coal, requires careful management of the socioeconomic effects on workers and local communities. Many countries have already pledged coal phase-outs, highlighting a growing momentum for change. For instance, members of the Powering Past Coal Alliance (PPCA) have pledged to phase out unabated coal by 2030, while Germany has set a later deadline of 2038 to allow more time for society and the economy to adjust. In North America, the decline of coal has been primarily driven by the availability of inexpensive shale gas and the ageing of coal infrastructure, complementing the Biden Administration's goal of achieving carbon-free electricity by 2035. Canada also plans to phase out by 2030. These transitions underscore the need for just-transition measures and robust social programmes to support affected workers, invest in alternative livelihoods and strengthen local economies during the shift to cleaner energy (Jewell et al. 2019; Blondeel, Van de Graaf and Haesebrouck 2020; United States Energy Information Administration [US EIA] 2023). From an environmental standpoint, transitioning to renewable energy reduces carbon emissions but it also brings new challenges. Building renewable energy infrastructure, including onshore and offshore wind,

Figure 19.4: Projected power generation (including heat) across income groups



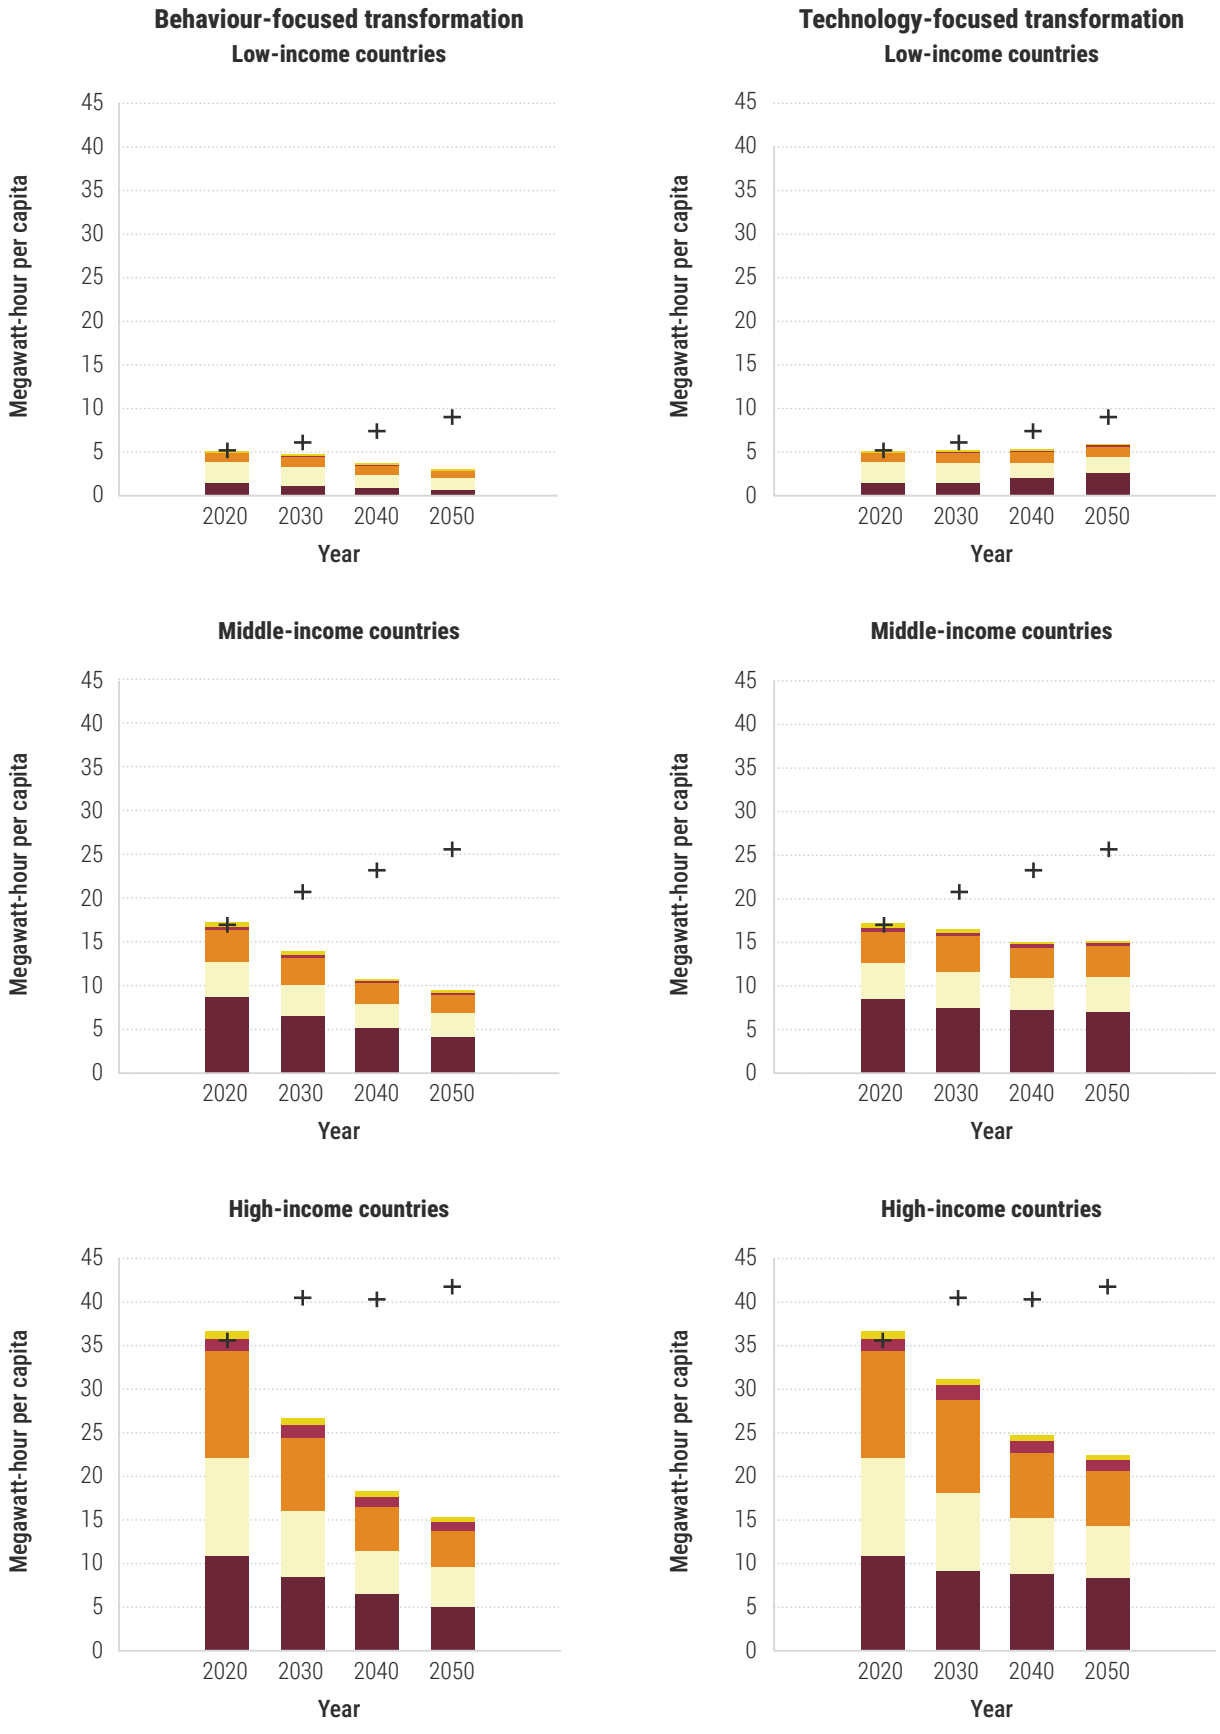


Figure 19.5: **Projected final energy demand per capita across income groups under behaviour-focused and technology-focused transformation pathways**

hydropower, and solar photovoltaic, can adversely affect protected regions, key biodiversity hotspots, and wilderness areas, though these impacts are generally limited (Rehbein et al. 2020). Such developments also contribute to larger environmental and societal problems like biodiversity decline, air pollution, and land degradation (Wang et al. 2022a).

19.5.2 Energy challenges and opportunities for middle-income countries

Energy systems in MICs vary widely. In Brazil, renewable energy makes up about 50 per cent, mainly from hydropower and biofuels, backed by strong regulations (Simon et al. 2018; Denny 2020; IEA 2023a). In contrast, renewable energy share in China is roughly 9 per cent, with expansion driven by carbon reduction targets (Song, Jia and Jiao 2022; Wang et al. 2022b; IEA 2023a). Despite growth in renewables, coal still supplies 60 per cent of energy in China, though demand growth is slowing (Lamb et al. 2021). In Southeast Asia, renewables constitute 20 per cent of the energy mix, indicating a gradual transition (Lau et al. 2022; IEA 2023a).

The difference is even more pronounced in electricity generation. In Brazil, 88 per cent of electricity comes from renewable sources, mainly hydroelectric power, aligning with Central and South America's average of 73 per cent. Meanwhile, the share of renewable electricity in China stands at 30 per cent, and Southeast Asian MICs average 28 per cent (Kroposki et al. 2017; Azhgaliyeva and Mishra 2022; Feng, Song and Chen 2023; IEA 2023a).

Several key factors are essential to enabling the energy transition in MICs. First, speeding up the shift toward renewables while managing existing fossil fuel dependencies requires addressing infrastructure challenges, especially in rapidly urbanizing areas. Regulation is also crucial, as shown by China's efforts to expand clean energy under its carbon reduction goals (Feng, Song and Chen 2023). Additionally, building an enabling environment for investment in renewable energy projects is also key. In Southeast Asian MICs, for instance, insufficient incentives have slowed progress despite new subsidy proposals (Johnson, du Pont and Gueguen-Teil 2021; Azhgaliyeva and Mishra 2022). Managing existing and planned fossil fuel infrastructure, particularly coal power plants, remains another critical challenge.

Figure 19.4 shows projections for power generation in MICs under the Technology-focused and Behaviour-focused Transformation Scenarios. The Behaviour-focused Scenario suggests a stabilization in total power generation through to 2050, with non-biomass renewables becoming the dominant source. Meanwhile, the Technology-focused Transformation Scenario shows a continued increase in power generation, also accompanied by a significant shift to non-biomass renewables. The Behaviour-focused Transformation Scenario reflects improved energy efficiency and reduced demand through lifestyle changes.

The energy transition involves more than just electricity generation; it also includes the energy directly consumed by end users. Figure 19.5's middle panels show these changes. The Behaviour-focused Transformation Scenario predicts a decline in final energy demand per person across all sectors by 2050, mainly due to reduced activity, increased efficiency, and lifestyle shifts. The Technology-focused Transformation Scenario also indicates lower final energy demand per capita compared to the Current Trends baseline. However, changing lifestyles will require targeted policy efforts, a challenge shared with high-income countries (Mi et al. 2020; Wang et al. 2022c). Regional differences in energy needs and resource availability, like the uneven distribution of oil, gas, coal, and hydropower in middle-income countries in East and Southeast Asia, further complicate the transition (Wiedenhofer et al. 2017; Bhattacharyya 2017).

The transition to renewable energy in MICs has both socioeconomic and environmental impacts. On the positive side, renewable energy initiatives can help reduce poverty. For instance, the Income and Energy Generation Programme in Brazil and Photovoltaic Poverty Alleviation programme in China have demonstrated how renewables can promote social progress (Barroco Fontes Cunha et al. 2021; Liu et al. 2023). However, expanding renewables can also lead to conflicts. 'Green' narratives may be exploited to justify land acquisitions, leading to tensions (Backhouse and Lehmann 2020).

Environmentally, the transition provides opportunities to reduce CO_2 emissions, but it also brings challenges. Like HICs, MICs' renewable energy infrastructure can impact protected areas and key biodiversity zones (Wang et al. 2025). Expansion of such renewables as hydropower and biofuels has caused biodiversity losses and habitat fragmentation (Pratiwi and Juerges 2020). Moving towards non-biomass renewables offers a more sustainable route, balancing electricity needs with CO_2 reduction goals. (Hausman 2012; Siala et al. 2021).

19.5.3 Energy challenges and opportunities for low-income countries

Countries with low incomes face distinct energy challenges and opportunities. Their energy systems have a relatively high share of renewables in total energy supply and unique electricity generation patterns, influenced by socioeconomic conditions that increase energy demand. These countries are expected to undergo significant changes in their energy systems, with the potential for widespread adoption of cleaner technologies while balancing economic development needs.

In many LICs, particularly in Africa and India, renewables make up about 15 per cent of the total energy supply (IRENA and African Development Bank [AfDB] 2022; IEA 2023a). This share is relatively high compared to high- and middle-income countries, due to the abundance of untapped renewable resources. In electricity generation, LICs in Africa and India have a renewable share of around 23 per cent, while LICs in the Middle East lag behind with only 3.5 per cent (IEA 2023a). Hydropower is the main source of renewable electricity in Sub-Saharan Africa, leaving significant potential for expanding solar and wind energy (Olanrele and Fuinhas 2022).

Achieving a successful energy transition in LICs depends on several crucial actions. It is vital to speed up the move to renewables, while managing fossil fuel dependencies is essential. India aims to install 500 gigawatts of renewable capacity by 2030 demonstrates this ambition (Government of India 2022). However, substantial infrastructure issues need to be overcome, particularly in urban regions where underdeveloped distribution networks slow down the adoption of renewable energy (Shrestha and Kakinaka 2023).

In many LICs in Africa the slowdown in coal power development since 2016, excluding South Africa and Zimbabwe, mirrors shifting global attitudes against coal financing and offers a chance to adopt cleaner technologies (Diluiso et al. 2021). The energy transition's success hinges on implementing supportive low-carbon policies and enhancing the efficiency of foreign direct investment in renewable projects. Creating an enabling environment that eliminates institutional barriers and attracts investment is crucial to driving renewable energy adoption (Olanrele and Fuinhas 2022; Rashed, Yong and Soon 2022).

As shown in the bottom panels of **Figure 19.4**, both the Technology-focused and the Behaviour-focused Scenarios forecast an increase in power generation by 2050. This growth is more significant in the Technology-focused Transformation Scenario, while the Behavior-focused Transformation Scenario emphasizes efficiency and demand measures. In both cases, this expansion aims to satisfy increasing demand, with non-biomass renewables becoming the main energy source. Although the Technology-focused Scenario shows much higher total generation compared to current trends, the Behavior-focused Transformation Scenario remains closer to today's levels.

In LICs, energy transition must go beyond electricity to meet overall energy needs. Resource limitations on demand-side measures can be addressed through innovative financing, which helps reduce the high initial costs of energy-efficient technologies (Wolske and Stern 2018). As rising incomes and poverty reduction are expected to drive higher per capita energy use, it is essential to implement strategies that balance economic growth with energy efficiency (DeAngelo et al. 2021).

Figure 19.5 compares the differences in final energy demand per capita between the two scenarios. The Behaviour-focused Scenario predicts a gradual decline in energy demand per person from 2020 to 2050, highlighting the importance of behavioural changes and energy efficiency in supporting economic development. Conversely, the Technology-focused Scenario indicates an increase in per capita energy demand, emphasizing that clean and efficient technologies will be crucial to meet this growing demand. Both scenarios show lower overall final demand per capita than the Current Trends Scenario. While high- and middle-income countries are projected to see a decrease in per capita energy demand over time, low-income countries show a more complex pattern: the Behaviour-focused Scenario forecasts declining demand, whereas the Technology-focused Scenario shows increasing demand to support development needs, though both remain significantly lower than those of countries in other income groups.

The energy transition in LICs has wider socioeconomic and environmental effects. It presents substantial opportunities to enhance air quality, with research indicating that renewable energy subsidies help decrease environmental degradation (Abdulwakil et al. 2022). Additionally, higher renewable energy use

has been shown to improve sustainable development outcomes in low-income countries (Tweneboah-Koduah, Arah, and Botchway 2023).

19.6 Transformation of food systems

The global food system faces systemic challenges that require a fundamental shift in how food is produced, consumed, and approached overall. Each region faces distinct problems: HICs deal with obesity, land abandonment, and meat-heavy diets; LICs face malnutrition, hunger, and stunted growth; and MICs encounter a combination of these challenges.

With global food demand expected to rise by 2050, implementing sustainable solutions like reducing meat consumption, supporting local food production, minimizing food waste, and adopting innovative agricultural methods is crucial (van Vuuren et al. 2017). However, changing food systems requires coordinated, long-term efforts spanning technical, economic, cultural, behavioural, and social dimensions. Additionally, disparities in income levels and lifestyles across countries require tailored regional strategies. This section explores the challenges and opportunities for food system transformations across various economic settings.

19.6.1 Sustainable food production and consumption for greater resilience in high-income countries

Despite having access to natural resources and advanced technologies, HICs face significant food-related issues, including land degradation, obesity, and resource-intensive diets (Pollard and Booth 2019). While high-income countries face a lower risk of food insecurity, individuals in these countries report a significant decline in subjective well-being when they do experience it (Frongillo et al. 2019). Additionally, their heavy dependence on food imports weakens resilience, increasing risks of supply disruptions and price fluctuations, as seen during the COVID-19 crisis. In response, HICs often adopt short-term food relief strategies that may not fully address nutritional needs or align with dietary preferences (Godrich et al. 2023).

Improving food system resilience is crucial for many high-income countries, especially given the high risks associated with global supply chain disruptions (Vicente et al. 2021). Regionalizing diets, supporting organic farming, and boosting food self-sufficiency can help shorten supply chains and strengthen resilience. The Metropolitan Foodshed and Self-sufficiency Scenario, or the "foodshed model", as applied to Vienna and Bristol, demonstrates high potential for self-sufficiency based on regional and sustainable production. However, its implementation requires diversifying regional crops, reducing food waste and shifting consumption patterns.

Organic farming plays a crucial role in sustainable food systems, benefiting human health, animal welfare, and ecosystem health by minimizing external inputs (Basnet et al. 2023). Yet, fully realizing the foodshed model and organic practices requires broader transformative strategies.

A major challenge for HICs is aligning stakeholders on essential changes in agrifood systems. Reaching agreement on environmental and social goals can promote agronomic innovation and sustainable development, whereas conflicting economic interests might obstruct progress. Wojtynia et al. (2021) highlight that agricultural sustainability studies should explore how current economic models prevent sustainable solutions. For example, a transdisciplinary approach helped Dutch dairy farmers successfully lower greenhouse gas emissions.

Röös et al. (2020) highlight that shifting from meat-heavy to plant-rich diets can help address environmental and health concerns. However, cutting back significantly on meat may lead to nutritional deficiencies, requiring an increased cultivation of locally grown grains and legumes to maintain a balanced diet.

Several HICs have launched national initiatives aimed at reducing food waste, including public awareness campaigns and improved food labelling. For instance, some supermarkets now provide storage tips for products to help consumers extend the shelf life of fruits and vegetables (World Resources Institute [WRI] 2019).

Promoting a bioeconomy requires well-designed policy frameworks that address key drivers, such as GDP growth, demographic shifts, trade dynamics, and land-use policies (Sturm and Banse 2021). On the supply side, boosting agricultural productivity and reducing post-harvest losses are vital, while on the demand side, changing consumer behaviour and preferences

are equally important. A balanced policy strategy also needs to support sustainable biomass use for energy and materials, reduce environmental impacts, and transform societal attitudes towards consumption. (Sturm and Banse 2021).

However, this transition also requires advancements in production technologies and carefully addressing broader environmental pressures, including water and land use. In this regard, modelling tools and scenario analysis can offer critical insights for policymakers (Sturm and Banse 2021) (**Box 19.4**). Through multi-regional input-output modelling, Mangir and Şahin (2022) help to understand the emission intensity of imported goods, highlighting the significance of a consumption-based perspective and connecting final demand to the production processes across global supply chains.

19.6.2 Food challenges and opportunities for middle-income countries

For MICs, the primary challenge lies in the dominance of economic paradigms, where environmental considerations are often given lower priority. Several major factors pose significant risks to food security in this context. These include rapid land-use changes, especially the conversion or degradation of farmland, intensive crop production without sufficient soil recovery, an ageing farming population, increasing climate variability, spatial and temporal mismatches between water and land resources and grain production, as well as spatial imbalances between population, land, and the grain system. (Liu and Zhou 2021).

These challenges are further exacerbated by the decreasing share of household spending on food, while the makeup of food consumption remains mostly steady, especially in urban areas. This trend is driven by increased spending on non-food items such as housing, transportation, water, and energy (Putra, Tong and Pribadi 2020). The unchanged structure of food consumption provides limited financial motivation, leading farmers to be hesitant about adopting diverse or innovative cropping methods (Putra, Tong and Pribadi 2020). As a result, this may lead to land abandonment, which also raises equity concerns, as many farmers lack access to basic amenities and a decent standard of living (Waha et al. 2022).

Globalization has led to a dietary shift in MICs, moving away from traditional fresh foods like rice, lentils, millets, and local staples toward processed and ultraprocessed foods. There is also a noticeable difference in how food security is understood. While national Food Security Indexes often measure food security using infrastructure-related indicators, institutional stakeholders usually define it based on the consistent availability and accessibility of food for consumers (Nurhasan et al. 2022).

Box 19.4: Modelling food and land system in Australia

Due to the complexity of the food system, exploring scenarios that capture the relationship between all variables and account for future uncertainties is challenging. Neglecting these uncertainties may lead to ineffective sustainability issues, e.g., wrong timing or scale of efforts. To better manage land use for both agriculture and livestock, a model of the Australian food and land system has been developed (Navarro-Garcia et al. 2023). The FABLE (Food, Agriculture, Biodiversity, Land-use, Energy) Calculator enables scenario-based analysis, allowing systematic examination of how different parameter ranges influence model outcomes and helping to design resilient pathways towards sustainability with a broad portfolio of solutions. Among these solutions, livestock productivity and density, afforestation, and dietary shifts are crucial for meeting sustainability goals. Investing in these areas could have wide-reaching knock-on effects, helping countries with extensive pasturelands improve their export performance and environmental outcomes. For instance, increasing livestock productivity (or reducing demand) means more land for biodiversity protection and vegetation recovery in Australia. A mix of institutional policies and market incentives can promote afforestation needed to meet food and land system objectives. This could involve enforcing effective land-clearing regulations to safeguard primary forests, support forest regrowth and stimulate demand for land-based emission offsets.

Credit: wirestock/Envato

Encouragingly, many of these countries possess valuable resources, such as human capital and economic capacity, that can facilitate investment in more sustainable technologies and practices (Rother et al. 2022).

Another potential solution worth considering is promoting the acceptance and cultivation of neglected and underutilized species, which can enhance agrobiodiversity and support food and nutrition security (Siddique and Cuong 2018). In this context, designating Globally Important Agricultural Heritage Systems (GIAHS) sites capable of supporting traditional farming and addressing problems such as land abandonment could be a crucial step (Siddique and Cuong 2018).

To improve food system policies, particularly in terms of institutional collaboration, a series of reforms is necessary. These include the horizontal and vertical integration of institutions, promoting citizen science, ensuring meaningful stakeholder participation, and implementing smart agriculture to support sustainable farming (Hoey et al. 2021; Ahsan et al. 2024).

Advanced technologies, widely used in plant genome editing and crop improvement, hold great promise for achieving food security and zero hunger (Ahmad et al. 2021).

Addressing equity issues in the food system requires broader systemic change. Governments should focus on enhancing rural living standards by supporting rural transitions and smart agriculture, aiming to make farming a more appealing and viable career option. Substantial efforts are also needed from institutional, social, and behavioural angles to change existing perceptions and reposition farming as a respected and dignified occupation (Ahsan et al. 2024).

To tackle the challenges associated with mass food production, it is essential to cultivate a new food production culture that more effectively addresses issues of equity and vulnerability. Although proposed solutions often include advanced technologies and changes in consumption habits, these alone are insufficient. A greater emphasis should be on enhancing equity and good governance within food

Credit: ThanhTN90/Envato

systems (Turner et al. 2020). Conducting thorough vulnerability assessments and using their findings to influence policy reform, backed by financial investments and actionable plans, can play a vital role in reducing rural poverty, transforming food systems, addressing inequalities, and supporting livelihood diversification (Woodhill et al. 2022).

Given the rising demand for livestock-based foods in low- and middle-income countries, it is critical to anticipate the associated environmental impacts and adopt both soft and hard mitigation strategies to support food security. A promising method is targeted investment in the livestock sector. Boosting livestock productivity through market-oriented investments can help these countries improve food and financial security while lowering their environmental impact (Nurhasan et al. 2022).

Institutional stakeholders have shown support for reverting to traditional diets and decreasing reliance on processed foods as a food security strategy. Many countries are promoting traditional staples like millets and sago (Nurhasan et al. 2022).

19.6.3 Enhancing food security in low-income countries

Malnutrition – both macronutrient and micronutrient deficiencies – and limited dietary diversity continue to be major challenges in LICs. These problems hinder growth and development (Li, Yadav, and Siddique 2020; Picchioni, Goulao, and Roberfroid 2022). Recent data shows that food security challenges have led to a 19.5 per cent rise in malnutrition in Sub-Saharan Africa and a 14.6 per cent increase in Southern Asia (Cho 2022; FAO 2021).

Food insecurity in these areas is frequently connected to poor environmental conditions that impact agriculture, along with insufficient infrastructure (Pawlak and Kołodziejczak 2020). These infrastructure gaps lead to increased food waste and limit the adoption of smart farming techniques due to a lack of technical skills and trained workers. In many LICs, agriculture constitutes a high share of gross domestic product (GDP), which exacerbates economic instability. Furthermore, agricultural systems in these contexts are especially vulnerable to the effects of climate

change. The lack of government support, ongoing dependence on traditional farming methods, and limited access to modern agricultural technologies weaken the ability to adapt, reduce impact, and build resilience against the pressures of population growth and climate change (Ceesay and Ndiaye 2022).

Population density significantly influences food security, as higher population concentrations increase the demand for land, water, and fertilizers to sustain food production (Agyemang, Kwofie and Fabrice 2022; Miladinov 2023). Although some low-income countries with lower population densities have abundant natural resources, they often struggle to achieve sustainable food production due to limitations in technical expertise, institutional capacity, and access to modern agricultural methods. Addressing food security in rural areas, especially in terms of availability and access, involves improving agricultural infrastructure and increasing household purchasing power (Wudil et al. 2022). Mekonnen et al. (2021) highlight the need for policymakers to carefully balance dietary guidelines with economic realities. For instance, promoting dairy over more affordable, locally available foods like vegetables, starchy staples, and fruits can be financially unsustainable for low-income families. At the same time, encouraging the intake of affordable, protein-rich foods should be prioritized over catering to household taste preferences to ensure sustainable food system management.

Households with limited financial means and insufficient knowledge of dietary and crop diversity are especially prone to food insecurity. Therefore, promoting access to decent work and launching basic education programmes to enhance food and nutrition literacy are essential components of public health strategies targeting the reduction of household food insecurity and malnutrition in low-income settings (Militao et al. 2023).

In low-lying delta regions like Bangladesh, water salinity and frequent flooding pose increasing threats to food security. In such areas, shifting emphasis from traditional farming, both crop cultivation and aquaculture, to livestock farming (such as cattle, sheep, and poultry) offers a promising strategy for developing climate-resilient livelihoods (Verhagen et al. 2022). This change may not only boosts adaptive capacity but also can improve nutrition by increasing access to protein-rich foods. While enhancing crop yields remains important, there's ongoing debate about whether it's sustainable to keep maximizing harvests with high-yield crop varieties, especially in areas that might have already reached their biophysical or ecological limits. Nevertheless, Popp et al. (2017) note that many decision makers in low-income regions still see potential to close current and future yield gaps by adopting advanced scientific agricultural methods, which could significantly increase crop production. Complementary approaches like capacity building for local agricultural officers and transferring suitable technologies from high-income countries are effective strategies to close yield gaps and support more sustainable agricultural growth.

The future challenges and opportunities for food system transition or food security are be reflected in land-use changes, serving as an indicator. The implications of these land-use changes on land availability across three income groups are depicted in Figures 19.6 and 19.7. Two transformation scenarios – a Technology-focused and a Behaviour-focused – are used to model future trends. The projections estimate and compare land cover changes from 2020 to 2050, focusing on shifts in intensive land uses, such as cropland and pasture, and extensive land uses, including forests and other natural lands, across both scenarios.

Figure 19.6 illustrates that high-income countries experience a slight decrease in pasture, compensated by gains in cropland and modest improvements in forest and natural land under the Technology-focused Scenario. In contrast, the Behaviour-focused Scenario shows a notable shift, with a substantial replacement of pasture by forest and natural land. Middle-income countries see an expansion of cropland, forest, and natural land at the expense of pasture in both scenarios. Low-income countries, however, experience a significant reduction in cropland in favour of forest and natural land in the Technology-focused Scenario, and a reduction in both cropland and pasture in the Behaviour-focused Scenario.

Figure 19.7 shows that high-income countries have twice the land per person compared to middle-income countries and three times that of low-income countries. However, in all future scenarios, as the population in HICs grows, rising from 955 million in 2020 to 1,080 million in 2050, the amount of land available per person is expected to shrink. In the technology-

Figure 19.6: Changes in land cover for intensive land use (cropland and pasture) vs extensive land use (forest and other natural lands) comparing the current trends to the behaviour-focused and technology-focused transformation pathways from 2020 to 2050

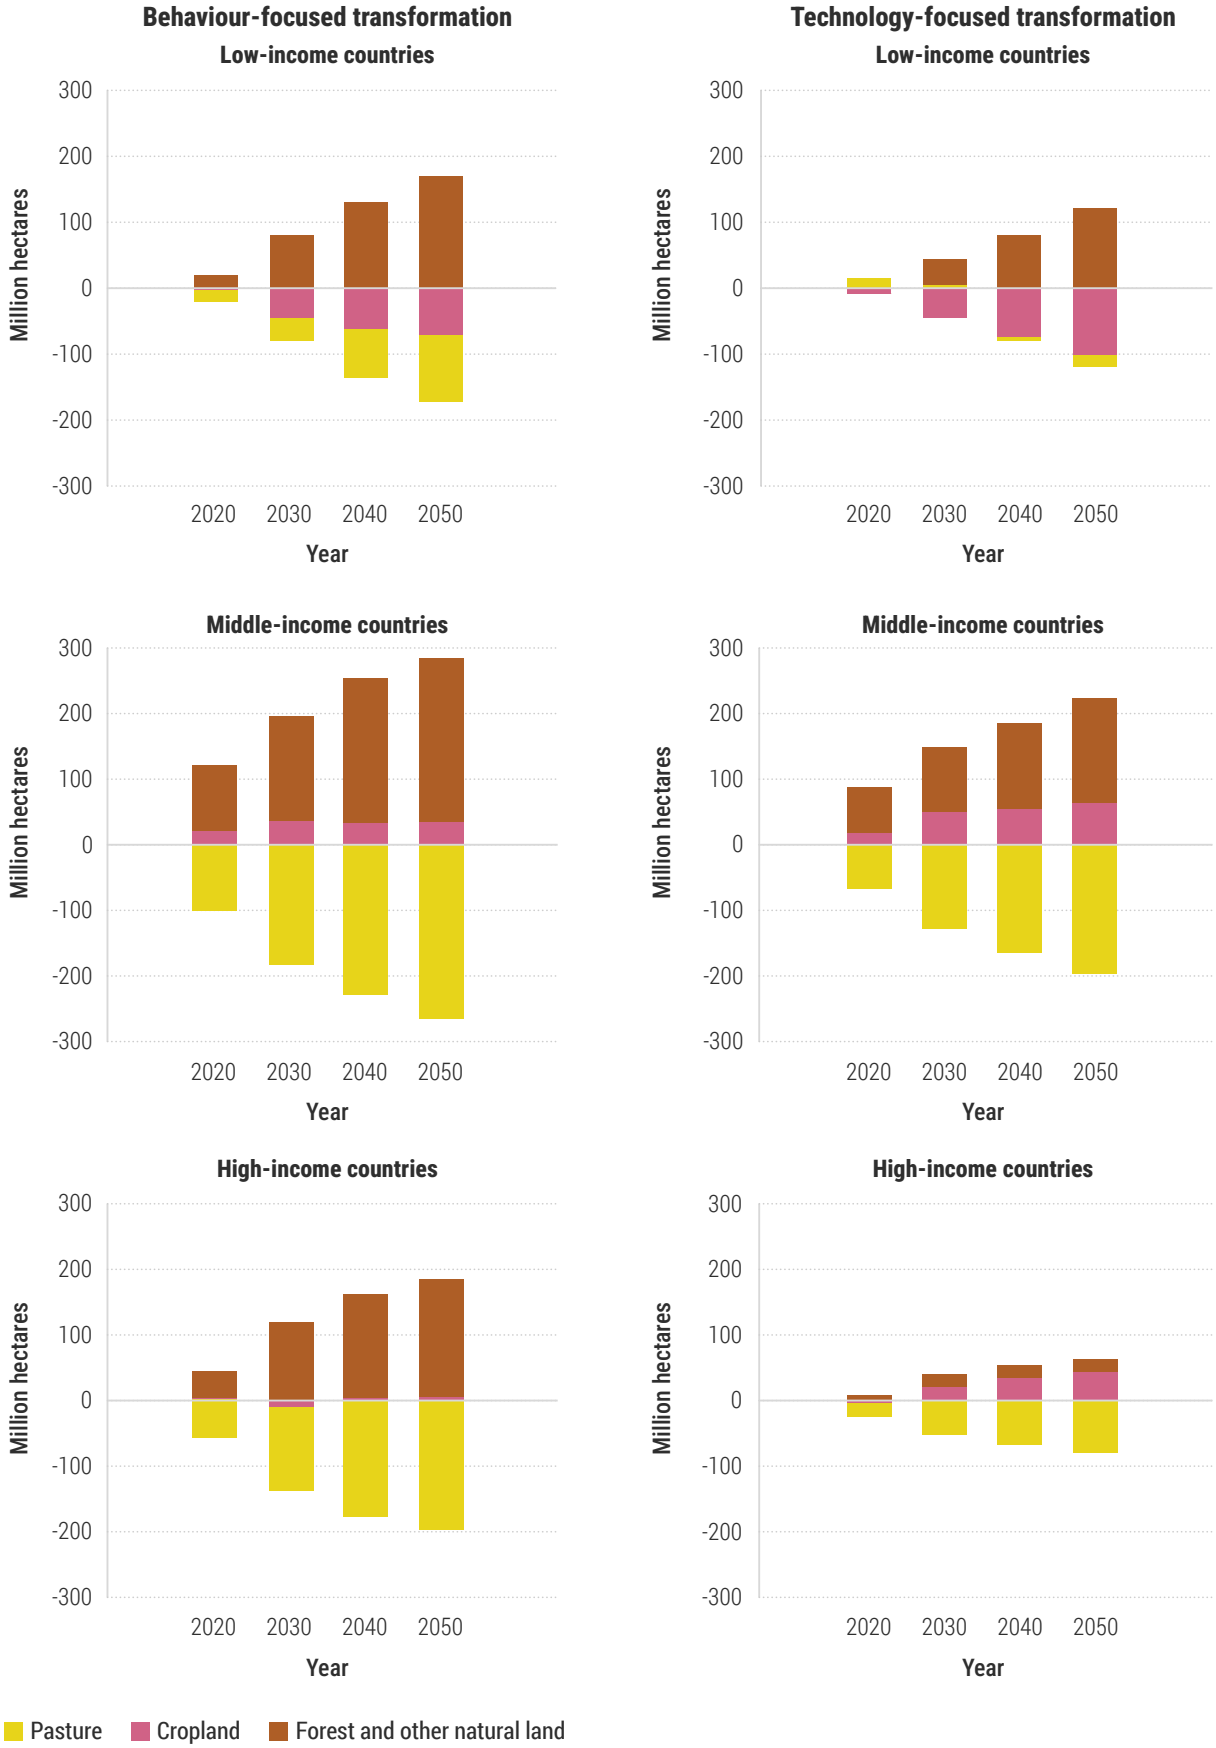

Figure 19.7: **Land availability of cropland, pasture, and forest and other natural lands for the current trends, technology-focused and behavioural-focused scenarios from 2020 to 2050**

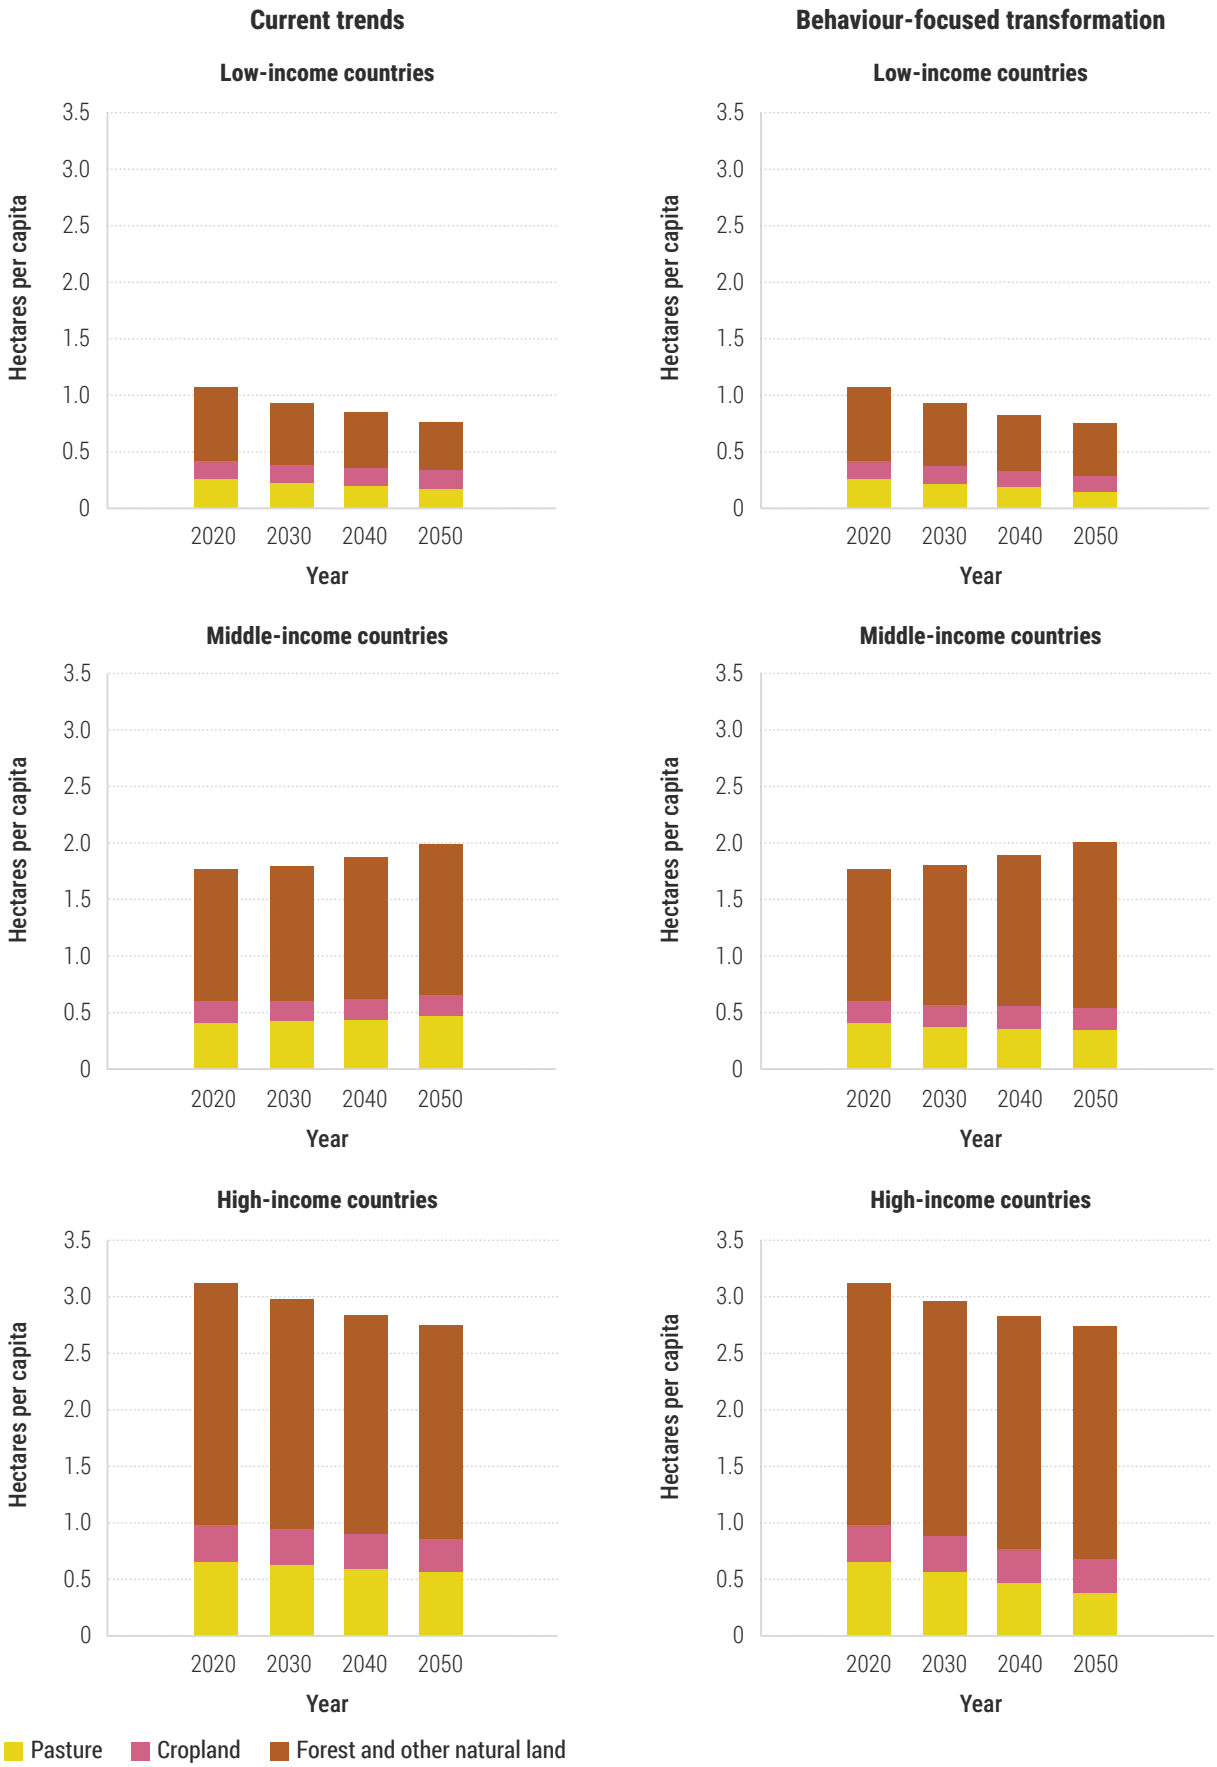

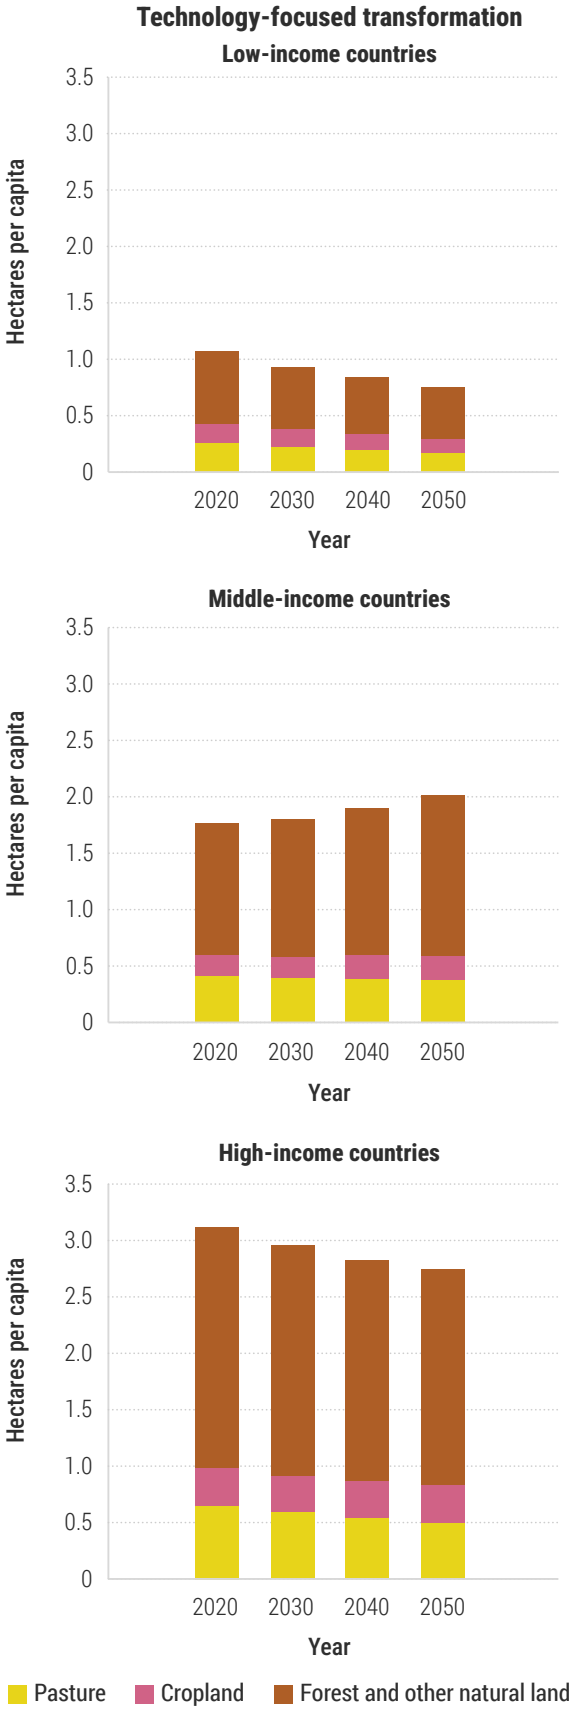

Figure 19.7: Land availability of cropland, pasture, and forest and other natural lands for the current trends, technology-focused and behavioural-focused scenarios from 2020 to 2050

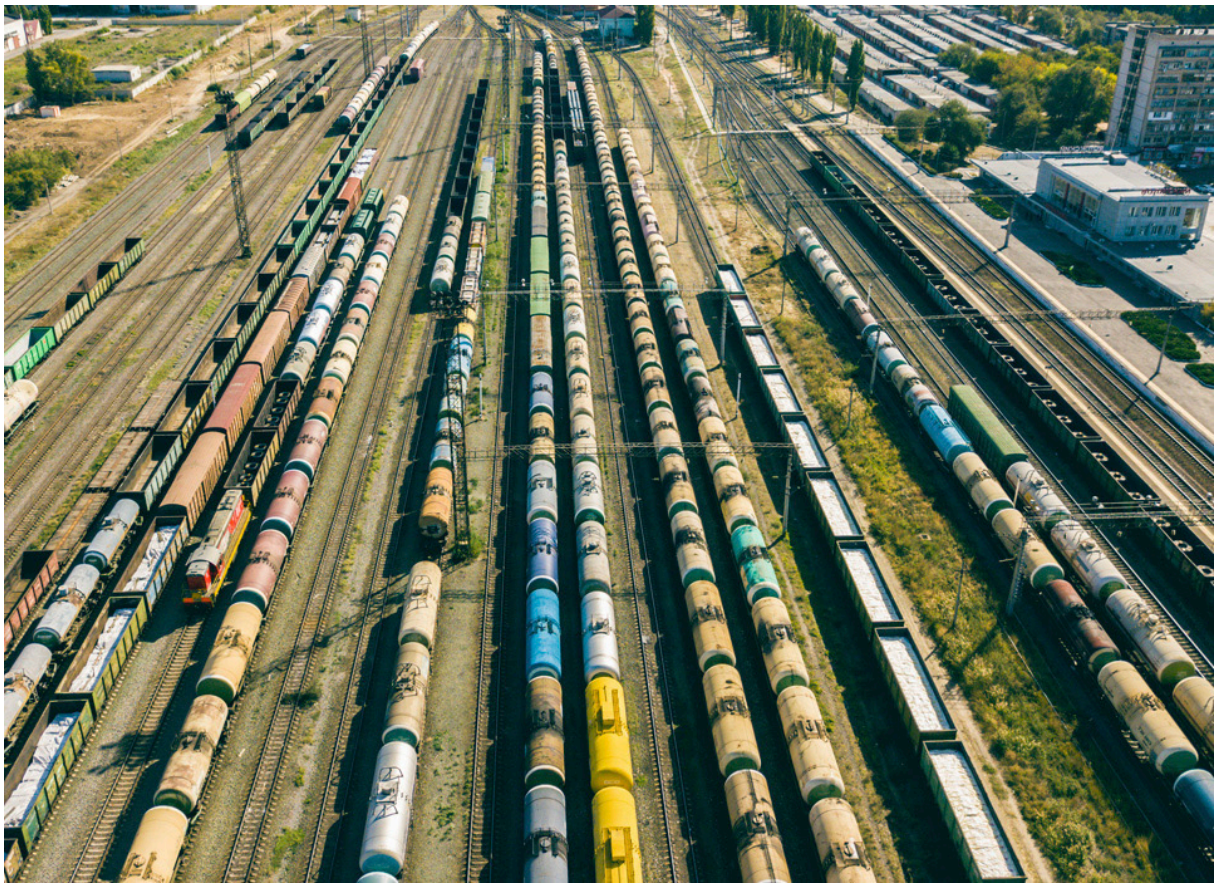
focused scenario, cropland per person increases from 0.3 ha in 2020 to 0.34 ha in 2050. Meanwhile, the development scenario focused on behaviour change is projected to preserve the most forest and natural land, at 2.06 ha per person.



From 2020 to 2050, middle-income countries are expected to have 0.19 ha of land per person in the reference scenario. This increases slightly to 0.22 ha in the Technology-focused scenario. In the Behaviour-focused Scenario, pasture land becomes more limited, but there is more forest and natural land.

According to the projections of the reference scenario in low-income countries, the amount of land per capita is expected to be 0.16 ha but drops to 0.13 ha in the Technology-focused Scenario and to 0.14 ha in the Behaviour-focused Scenario. In countries of this income group, people have similar amounts of cropland and pasture land, but pasture is lowest in the Behaviour-focused Scenario, which preserves the highest amount of forest and natural land, at 0.47 hectares per capita. These patterns are shaped by a significant population growth, from 3.1 billion to 4.4 billion people.

The extremely high land pressure in low-income countries likely affects food security and biodiversity loss. While growth in absolute forest and natural land across the three economic groups in both transformation scenarios, compared to the reference scenario, may help prevent biodiversity loss, it also reduces food production, export potential, and overall food security.

19.7 Transformation of environmental Systems

Humanity has breached six of the nine planetary boundaries crucial for maintaining a safe and equitable operating space (Richardson et al. 2023; Ross 2020), and is considerably behind in meeting the SDGs by 2030. To stay within planetary boundaries and achieve the SDGs, a holistic transition that reduces greenhouse gas emissions, limits pollution, and prevents biodiversity loss is necessary. Environmental challenges and opportunities vary across countries, shaped by demographics, economic conditions, gender, and vulnerabilities to climate change. Achieving sustainability requires tailored strategies that address these differences.

Credit: MikeShots/Envato

19.7.1 High-income countries' environmental responsibilities extend beyond their own borders

Environmental challenges in HICs are well-documented, including issues like excessive consumption and waste (Wiedmann et al. 2020; Garcia et al. 2021; Hickel et al. 2022), biodiversity loss driven by urbanization (McDonald et al. 2019) and industrial agriculture (Tilman et al. 2017; Hallmann et al. 2017), as well as pollution from outdated water treatmentfacilities (Khan et al. 2021; Wear et al. 2021), among other concerns.

A more concealed challenge for HICs is emissions outsourcing, mainly to lower-income countries. Emissions outsourcing here refers to the transfer of emissions (e.g., greenhouse gases, $PM_{2.5}$, SO_2) by shifting polluting industries to nations with weaker emission rules (Abbasi and Bouman 2020). Generally, HICs tend to have stricter regulations on GHGs and pollution compared to middle- and low-income countries (OECD 2016). Emissions outsourcing is a business decision to avoid regulatory compliance costs, often as an unintended result of national emission laws. High income countries then importing goods containing "embodied emissions" (Choi and Yu 2018; Ambrose et al. 2023), which are emissions produced in the upstream supply chain before import (Baker 2017; Wang et al. 2024). This practice can retain their consumption patterns and create a misleading sense of environmental progress in HICs while potentially increasing emissions overall (Baumert et al. 2019; Dar et al. 2022).

Globalized supply chains and the shift of extractive industries to middle- and lower-income countries also have other environmental impacts. For example, food imports to HICs lead to deforestation and biodiversity loss abroad (Searchinger et al. 2022; Wiebe and Wilcove 2025). Similarly, importing cobalt can lead to toxic run-off in producing regions (Calvão, McDonald and Bolay 2021), while exporting wastes and recycling to countries with limited treatment capacity shifts the pollution burden (Cotta 2020). See also **Box 19.5**.

Regarding GHGs, emissions outsourcing can be promoted through the production-based emissions accounting required by the Paris Agreement (Dar et al. 2022). This framework enables outsourcing nations

Box 19.5: European Green Deal initiatives for environmentally responsible sourcing

The EU is implementing responsible sourcing policies across key trade sectors as part of the European Green Deal. In October 2023, the EU introduced the Carbon Border Adjustment Mechanism (CBAM). This policy imposes carbon emission tariffs on various industrial imports. The goal is to prevent EU producers from relocating polluting activities to countries with weaker environmental standards (Bellora and Fontagné 2023). The CBAM fee is based on the difference between the EU Emission Trading System's carbon price and the price that the exporting country charges for emissions (Clausing et al. 2024). This phased-in programme will begin in 2026 (European Commission 2023). Carbon tariffs are expected to generate positive spillover effects by encouraging exporting countries to implement their own carbon pricing, thereby motivating industries to reduce emissions (Clausing et al. 2024).

The European Union Deforestation Regulation (EUDR) will impose due diligence rules on traders to guarantee deforestation-free sourcing of palm oil, cocoa, coffee, soy, rubber, cattle, timber, and related products (European Commission 2024). It is set to come into force in December 2025 (European Commission 2024).

Credit: chuyu2014/Envato

to lower their officially acknowledged carbon emissions without decreasing their consumption of products that contain embodied emissions. Carbon carbon tariffs have been suggested to address carbon emissions outsourcing (Larch and Wanner 2017; Kopp, Pizer and Rennert 2023), though none are currently fully implemented.

To soften the economic impacts of carbon tariffs on lower income countries, revenues generated from CBAM can be used to support exporting nations in acquiring the technology needed to fulfil CBAM standards (Do 2025). In the case of the EUDR, the EU is forming partnerships with exporting countries to facilitate technology transfer to prevent deforestation (European Commission 2024) (**Box 19.5**). This approach aligns both CBAM and EUDR with the Technology-focused Transformation Scenario outlined in Chapter 11.

From the Behaviour-focused Transformation Scenario of Chapter 11, eco-certification, such as

the Rainforest Alliance, provides information to assist environmentally responsible consumers in HICs in choosing sustainably produced imported products (Pinto et al. 2014). Additionally, digital carbon tracking apps can help consumers steer clear of imported goods with a high carbon footprint (Hoffmann et al. 2024).

Figure 19.8 illustrates simulated per capita GHG emissions and biodiversity loss trends from 2020 to 2050 in HICs. Although the policies mentioned earlier are not explicitly included in the scenarios, each can be seen as supporting different transformation scenarios.

In terms of per capita GHG emissions, the Behaviour-focused Scenario proves more effective than the Technology-focused one, mainly due to the assumption of strong consumer demand for more climate-conscious products.

For biodiversity, both transformation scenarios offer similar benefits. Although biodiversity declines across all three scenarios, by 2050, the decline is less pronounced for the two transformation scenarios.

19.7.2 Re-setting priorities in industrializing middle-income countries

MICs face the challenge of balancing the urgent need to raise living standards with the need to ensure environmental sustainability. Governments in MICs prioritize improving living conditions through industrialization, often placing environmental quality lower on the agenda. Van Rooij and McAllister (2012) note that environmental regulation is more challenging in MICs than in HICs or LICs: "As national economies industrialize, economic interests greatly overwhelm environmental interests, undermining various forms of legal, political, and social action against polluting firms. A combination of weak enforcement and pervasive noncompliance tend to create a vicious circle that works against pollution mitigation and control."

In the initial stages, industrial development advances society by increasing incomes, employment, and delivering related benefits. However, under favourable policies and unconstrained by regulation, industry can expand quickly, leading to higher air pollution and

Figure 19.8: Simulated per capita GHG emissions and terrestrial biodiversity in percentage Mean Species Abundance (MSA) in high-income countries under current trends and behavioural-focused and technology-focused transformation pathways

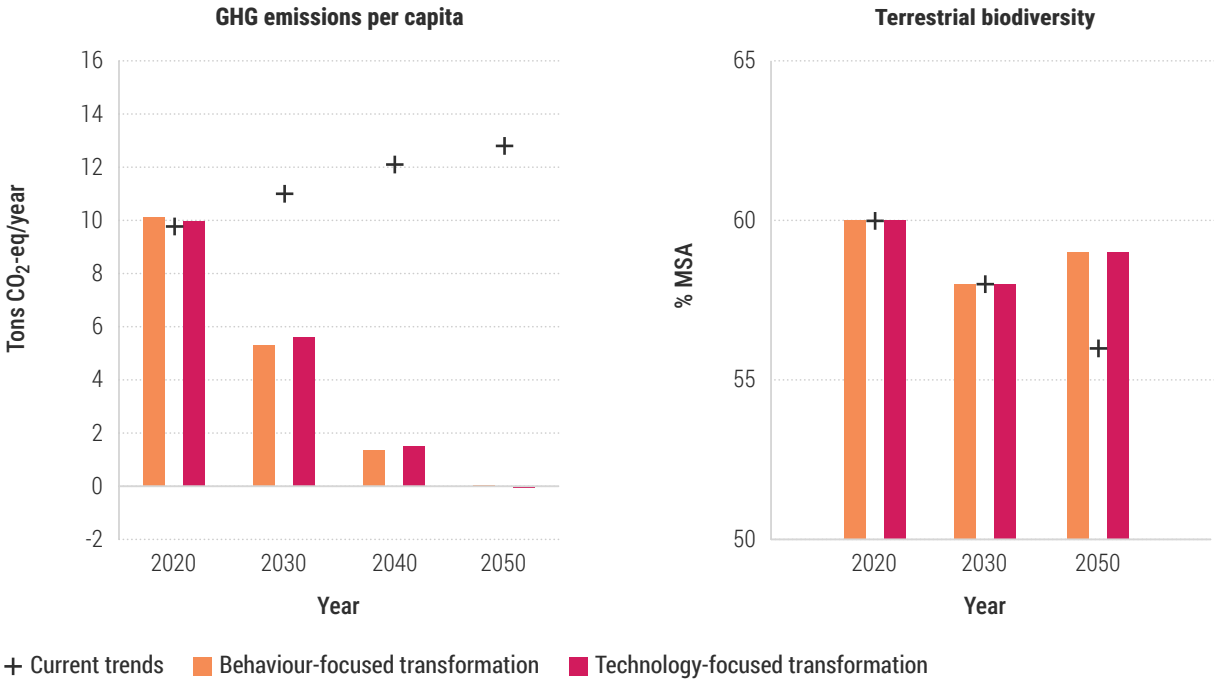
Note: Model output data was not available for biodiversity for the year 2040 and for clear comparison across the years, the values of the vertical axis in the terrestrial biodiversity graph start at 50% MSA

greenhouse gas emissions (Van Rooij and McAlister 2012). The World Bank highlights that air pollution is especially widespread in developing countries undergoing industrialization (Rentschler and Leonova 2023). Notably, $PM_{2.5}$ is a leading cause of respiratory diseases and mortality. $PM_{2.5}$ has been associated not only with asthma and other respiratory diseases but also with circulatory problems and cognitive decline, which can significantly reduce productivity and, ultimately, reduce economic well-being (Aguilar-Gomez et al. 2022). Low-income, marginalized populations, and the elderly face disproportionate exposure to air pollution and are more vulnerable to respiratory illnesses (Canaday, Georas and Croft 2024). These health effects can create a feedback loop that compromises the social benefits gained from industrialization. Often, there is a delay in recognizing the impact of pollution, allowing pollution levels to rise before governments respond (Fuller et al. 2022).

Possible strategies include providing incentives for the adoption of clean technologies and fuels, eliminating fossil fuel subsidies, and offering affordable healthcare in industrial regions, as the poorest communities suffer from pollution the most. (Rentschler and Leonova 2023). Additionally, Rentschner and Leonova (2023) suggest incorporating environmental and health externalities into planning processes to protect vulnerable populations. Fuller et al. (2022) advocate for a swift, large-scale shift to renewable energy, which would decrease ambient pollution and help mitigate climate change. Van Rooij and McAllister (2012) highlight the importance of effective regulation in MICs. They argue that regulatory agencies must work together with citizens affected by industrial pollution to encourage industry compliance with regulations. Fuller et al. (2022) emphasize the importance of monitoring pollutants and public concern regarding pollution and health, stating that "the public demand for more effective action against pollution by governments can be powerfully catalytic." See **Box 19.6**.

Figure 19.9 shows simulated trends in per capita greenhouse gas emissions and biodiversity for MICs. The differences between the Behaviour-focused and Technology-focused Transformation Scenarios are minimal for both indicators. Under the current scenario, per capita GHG emissions in MICs are projected to steadily increase through 2050, whereas **Figure 19.8** shows that in HICs emissions initially rise and then decline - a trend consistent with the earlier discussion about emissions outsourcing. Despite the upward trajectory under the current scenario, both transformation scenarios in MICs offer a huge potential for reducing GHG emissions.

19.7.3 Systemic threats to the environment in low-income countries



Countries with low incomes often heavily rely on their natural resources to meet their basic needs, which can create vicious cycles of resource decline and poverty (Ngonghala et al. 2014). Unsustainable agriculture practices are considered one of the most serious environmental threats in LICs (Sarkodie and Owusu 2022). As populations grow, the need for food and livelihoods drive agricultural expansion, placing pressure on forests, habitats, and biodiversity, and may result in human-wildlife conflicts (Gross et al. 2021). Intensive land use is often a response to limited arable land availability, which itself is the result of population pressure and land degradation from unsustainable land management (Sarkodie and Owusu 2022).

To mitigate ecological harm caused by agricultural expansion and unsustainable practices, the FAO promotes agroecology. It defines this approach as "the science of applying ecological concepts and principles to manage interactions between plants, animals, humans, and the environment for food security and nutrition" (FAO 2019). Agroecology reduces reliance on synthetic chemicals and relies on ecological science and Indigenous Knowledge (Utter et al. 2021; Ntamwira et al. 2023). The importance of semi-natural habitats, such as forests, for pollination and other ecosystem services in agricultural systems is also acknowledged (Ulyshen

Box 19.6: Social media voices influence on air quality improvement in China

Wang and Jia (2021) conducted a study social media can exert bottom-up pressure on air quality governance in China. Analysing data from Weibo, researchers observed that a 10 per cent increase in environmnet-related posts was associated with a 2.7 per cent reduction in $PM_{2.5}$ levels.This suggests that growing public attention online could play a role in shaping government action on air quality.

Figure 19.9: Simulated per capita GHG emissions and terrestrial biodiversity in percentage Mean Species Abundance (MSA) in middle-income countries under current trends and behavioural-focused and technology-focused transformations

Note: Model output data was not available for biodiversity for the year 2040 and for clear comparison across the years, the values of the vertical axis in the terrestrial biodiversity graph start at 50% MSA.

et al. 2023). Promoting biodiversity is essential for natural pest control and pollination.

Agroecology focuses on building and maintaining soil organic matter, which can help mitigate climate change by turning agriculture from a source of carbon emissions into a carbon sink (Leippert et al. 2020). Along with similar strategies like agroforestry, agroecology also enhances resilience to climate change by improving soil stability and moisture retention (Dittmer et al. 2023). Nonetheless, there are risks involved. It takes time to improve soils, and yields may temporarily decline after adopting these practices, which could hinder efforts to scale agroecology (Morais et al. 2021). Successfully scaling agroecology will depend on capacity building and policies that promote adoption. These might include tax incentives, subsidy programmes, certification schemes, and price premiums (Miles, DeLonge and Carlisle 2017).

As populations and agriculture expand, human-wildlife conflicts in LICs are rising, mainly affecting smallholder farmers and pastoralists (World Bank 2023b). These conflicts worsen due to increasing resource scarcity driven by climate change (Abrahms 2021). The World Bank encourages governments to establish a shared vision among stakeholders for coexistence with wildlife (World Bank 2023b). Effective policies include installing physical barriers, compensating for wildlife-related damages, and providing employment in wildlife tourism, among other measures (Gross et al. 2021) (**Box 19.7**).

LICs suffer the most from climate change impacts, despite HICs being the primary contributors to global GHG emissions (United Nations Environment Programme [UNEP] 2023a). Effects include more frequent and more severe droughts and flooding (IPCC 2021). The 2023 UNEP Emission Gap Report estimates that LICs need 10 to 18 times more funding for climate adaptation than is currently available (UNEP 2023). It emphasizes the need for increased international, domestic, and private sector financing, along with improved international cooperation and reform of the global financial system (UNEP 2023). Adaptation investments must be tailored to local circumstances.

There is also a need to develop local capacities for managing natural resources in climate adaptation

Box 19.7: Human-wildlife coexistence, Chitwan National Park, Nepal

At Chitwan National Park in Nepal, integrated buffer zone management has led to a 75 per cent decrease in livestock predation by tigers over the last decade, despite a 143 per cent increase in the tiger population from 38 in 2000 to 92 in 2018. The Nepali Government requires that 30 per cent of all park entry fees benefit nearby villages in buffer zones, supporting community development to sustain forest resources and improve human-wildlife coexistence. Additionally, a fund has been established to compensate villagers for wildlife-related losses involving species such as rhinoceroses, elephants, tigers, leopards, and bears (Gross et al. 2021).

efforts (Williams et al. 2020). Beyond securing financing, this involves integrating climate change adaptation into national policies and strengthening institutional frameworks (IPCC 2014). Nature-based solutions should take priority; examples such as wetland and mangrove restoration, along with watershed reforestation, offer cost-effective, multi-faceted benefits. These include enhancing resilience against climate change-triggered storms and floods, while also supporting biodiversity and improving water quality (World Bank 2022).

Figure 19.10 shows that the LICs' per capita GHG emissions are much lower than those of the HICs (**Figure 19.8**) and the MICs (**Figure 19.9**). The current trend is projected to steadily increase; however, the transformation scenarios have the potential to significantly reduce GHGs by 2050. Both scenarios also decrease biodiversity loss. However, biodiversity in 2050 remains lower than in 2020 under both transformation scenarios, despite an increase in forest cover shown in **Figure 19.6.** This aligns with the observation that biodiversity recovery can require lengthy time delays, spanning decades or centuries (Ackleh *et* al. 2018, Rozendaal *et* al. 2019). Assisted Natural Regeneration (ANR) (Shono et al. 2020) and species reintroduction (Seddon et al. 2014) may help overcome these challenges to biodiversity recovery.

Figure 19.10: Simulated per capita GHG emissions and terrestrial biodiversity in percentage Mean Species Abundance (MSA) in low-income countries under current trends and behavioural-focused and technology-focused transformations

Note: Model output data was not available for biodiversity for the year 2040 and for clear comparison across the years, the values of the vertical axis in the terrestrial biodiversity graph start at 50% MSA.

19.8 Implications for the three economic groups

This chapter discussed managing transitions across five system dimensions for countries in different income/economic groups. **Table 19.1** below summarizes the opportunities worth considering.

19.9 Summary and conclusions

Countries at different levels of economic development – HICs, MICs, and LICs – face distinct challenges and opportunities in their path to sustainability. Tailored strategies are necessary for each group to achieve its environmental,

Table 19.1: Summary of opportunities for different economic groups by system

System	Low-income	Middle-income	High-income
Economic system	Seek green finance, to accelerate development goals. Strengthen capacity in sustainable finance.	Reorient public funds and provide incentives for the private sector to value the environment and avoid environmental risks. Invest in resilient infrastructure for long-term economic returns.	Align multilevel and multilateral governance, macroeconomic and fiscal policy with sustainable financing. Explore "post-growth" and "degrowth" economic models.
Towards circularity	Promote and engage the informal sector in resource recovery.	Invest in resource-efficient buildings and infrastructure.	Leverage technology for resource management and waste minimization.
	Ensure effective waste management and resource recovery.		
		Transition to resource-efficient production and consumption. Develop a workforce equipped for green technologies.	
Energy system	Expand access to clean and affordable energy. Develop decentralized and off-grid energy solutions. Leverage climate financing and investment.	Scale up clean energy technologies. Improve grid infrastructure and reliability. Promote energy-efficient urbanization and industrial development.	Accelerate decarbonization of existing systems. Enhance energy efficiency and demand management. Electrify transport and heating.
	Plan for coal phase out and reform fossil fuel subsidy. Develop and promote renewable energy and storage.		
Food system	Invest in agricultural infrastructure. Promote affordable, healthy diets in poor, rural areas.	Make farming an attractive career choice. Invest in livestock productivity. Promote cultivation of neglected and underutilized species. Encourage a return to traditional diets.	Enhance food security and food system resilience through higher self-sufficiency and shorter supply chains. Promote plant-based diet.
	Promote agroecology to improve soil health and yields.	Reduce food waste through education, public awareness, financial incentives, supply chain technologies, smart product labelling, on-farm solutions.	
Environmental systems	Develop mutually beneficial coexistence with wildlife. Build local capacity for climate adaptation. Support community-led conservation programmes and nature-based solutions.	Incorporate environmental and health externalities in planning decisions. Monitor and enforce pollution control and reduction measures.	Impose carbon tariffs on imports. Use eco-certification to guide consumer behaviour.
All systems	Support international action and cooperation in science, technology and innovation, and capacity building.		

Credit: seventyfourimages/Envato

social, and economic objectives. The key themes examined in this chapter include economic growth, circular economy, energy, food, and environmental systems across these economic groups, highlighting diverse solution portfolios for each.

HICs aim to decrease their environmental impact by implementing green technologies, supporting sustainable finance, and shifting to circular economy practices. These countries face challenges including high material use, large amounts of waste, reliance on imports, and outsourced carbon emissions. To lead global sustainability efforts, HICs needs policies that enhance resource efficiency, promote low-carbon innovations, and drive behavioural change.

Countries with middle incomes are experiencing rapid urbanization and economic growth. However, they face challenges in balancing development with sustainability. To transition effectively, it is crucial for these countries to invest in renewable energy, upgrade infrastructure, and promote circular economy practices. Additionally, overcoming dependencies on fossil fuels and creating resilient urban environments are essential steps in this process.

LICs encounter significant financial challenges and are particularly vulnerable to environmental degradation and climate change. International support, including targeted financing and technology transfer, plays an important role in their development. Key strategies for sustainable progress include enhancing governance, integrating the informal economy, and investing in climate-resilient infrastructure.

In terms of energy systems, HICs can lead by advancing electrification and expanding renewable energy, MICs can benefit from reducing reliance on coal, and LICs can explore the opportunity to leapfrog to renewable solutions suited to their infrastructure limitations, like off-grid and decentralized systems.

Food systems face unique challenges: HICs need to address overconsumption, MICs must balance food security and environmental impacts, and LICs must tackle undernutrition. Transforming these systems requires changing dietary habits, minimizing waste, and investing in sustainable agricultural practices and technologies.

Environmental systems emphasize the need to align global efforts with local contexts. HICs must address the outsourcing of environmental impacts, MICs face pollution issues from industrialization, and LICs require nature-based solutions for climate adaptation.

The chapter concludes that both the Behaviour-focused and Technology-focused Transformation Scenarios offer valuable guidance for advancing sustainability. Meaningful progress depends on cooperation, multilevel governance, and global solidarity. Realizing these transformations requires institutional reforms, innovative policies, and public engagement to ensure a balanced integration of environmental, economic, and social aspects within each country's development path.

Appendix 19.1: Country Data

Table 19.2 Data was utilized to formulate the country groupings.

Countries are divided into three main groups based on income level. These classifications follow the traditional income categories of the World Bank, which are determined using GNI per capita for 2022 (World Bank 2023a). In this analysis, low-income includes the traditional low to lower-middle category ($4,465 or less), the middle class covers those earning from US$4,466 to US$13,845 (upper-middle-income countries), and the high-income group remains the traditional high-income category ($13,845 or more). Population density is defined as the number of people per km² of land area. Data on population density was obtained from the Our World in Data 2022 data set (Ritchie et al. 2023). Countries are classified as either having high or low population density, based on the median value across all countries included in the analysis (median = 8.55/km², n=197 countries). Additional data on the country's physical trade balance and status is included to inform the chapter analysis. 197 countries are included in the data set in accordance with the UN Statistics Division Standard Country or Area Codes for Statistical Use, also known as the M49 Standard.

Code	Country or area	Region	Income group	Population density	Population density class	Trade Status
AND	Andorra	Western European and Other Groups	High	169.88	High density	Importer
ARE	United Arab Emirates (the)	Asia and the Pacific	High	132.94	High density	Exporter
ATG	Antigua and Barbuda	Latin America and the Caribbean	High	213.12	High density	Importer
AUS	Australia	Western European and Other Groups	High	3.40	Low density	Exporter
AUT	Austria	Western European and Other Groups	High	108.33	High density	Importer
BEL	Belgium	Western European and Other Groups	High	384.94	High density	Importer
BHR	Bahrain	Asia and the Pacific	High	1875.46	High density	Importer

Appendix 19.2: Renewable energy use by region

Table 19.3 This table presents data from the World Energy Outlook 2023, focusing on the Stated Policies Scenario across various regions of the world.

The table presents information for 2022, including renewable energy supply in exajoules (EJ), total energy supply in EJ, the share of renewable energy supply relative to total energy supply, renewable energy generation in terawatt-hours (TWh), total energy generation in TWh, and the percentage of electricity generated from renewable sources compared to total electricity generation. The regions included are Africa, Asia and the Pacific, Brazil, Central and South America, China, the European Union, India, Japan, the Middle East, and North America. Russian Federation, Southeast Asia, the United States of America, and the World. These regions are based on the published data by IEA 2023a. Note that population density and income levels closely match, but not exactly, those in Annex I above, due to disparities in data aggregation. The regional categorization of the World Energy Outlook differs from the one of GEO-7.

REGION	Year	Population Density	Income Level	Renewable Supply (EJ)	Total Supply (EJ)	Renewables Share of Total Supply (%)	Renewables Generation (TWh)	Total Generation (TWh) Supply (EJ)	Renewables Share of Total Generation (%)
Africa	2022	Low	Low	5.765	36.422	15.8%	210.45	890.08	23.6%
Asia Pacific 2022 Low	2022	Low	High	30.486	281.025	10.8%	3932.02	14482.81	27.1%
Brazil	2022	Low	Middle	7.006	13.953	50.2%	593.71	677.17	87.7%
Central and South America	2022	Low	Middle	10.015	29.053	34.5%	1018.34	1388.83	73.3%
China	2022	High	Middle	14.875	159.7	9.3%	2681.36	8911.84	30.1%
Eurasia	2022	Low	Middle	1.303	41.575	3.1%	276.62	1476.08	18.7%
Europe	2022	High	High	14.869	78.164	19.0%	1619.63	3995.57	40.5%
European Union	2022	High	High	11.081	56.179	19.7%	1085.25	2795.4	38.8%
India	2022	High	Low	6.224	41.969	14.8%	398.87	1765.82	22.6%
Japan	2022	High	High	1.38	16.637	8.3%	224.83	1061.55	21.2%
Middle East	2022	High	Low	0.268	36.379	0.7%	44.93	1275.76	3.5%
North America	2022	Low	High	12.76	114.46	11.1%	1496.66	5524.04	21.1%
Russia	2022	Low	Middle	1.021	33.997	3.0%	204.54	1169.64	17.5%
Southeast Asia	2022	High	Middle	5.838	30.26	19.3%	340.05	1219.72	27.9%
United States	2022	Low	High	10.103	93.803	10.8%	972.9	4491.21	21.7%
World	2022	World	World	75.48	631.978	11.9%	8598.65	29033.19	29.6%

Appendix 19.3: Disaggregation of model data by country grouping

The grouping of countries in the modelling results differs from those in Chapter 19 because of how geographical regions are defined in the respective modelling tools. A more detailed explanation of these groupings can be found in Chapter 9 (9.5).

For the analysis, data from the IMAGE and IFs models, covering indicators such as primary energy, final energy, electricity generation, GHG emissions, biodiversity loss, water scarcity, pollution, and well-being, were available for the following countries:

High-Income: Canada, Japan, the United States of America, Western Europe, Oceania;
Middle-Income: Mexico, South Africa, Türkiye, Brazil, China, Indonesia, Russian Federation;
Low-Income: India, Rest of Southern Africa, Eastern Africa, Northern Africa, Rest of South Asia, Western Africa.

Whereas some regions, such as the "Rest of Latin America" and the "Middle East," are excluded from these income-density groupings because they include countries across different income categories, which would complicate the analysis. Additionally, the "Rest of Southern Africa" region is not included in the mapping for materials demand, waste and recycling, or economic data, which introduces discrepancies that should be noted when interpreting results.

For indicators from the AIMS model, data for the following countries within the respective income groups were available:

- High-Income: Canada, Japan, United States of America, EU, New Zealand and Australia
- Middle-Income: Türkiye, Brazil, China, Former USSR
- Low-Income: India, Northern Africa, Rest of Africa (including South Africa), Rest of Asia

System indicator (model output data)	
Economics	HDI (IFS) GDP per capita (IFS or GEM - E3 marker model) - Modelling team will provide
Food:	Water use (water withdrawal) (IMAGE & AIM*) Land-use change – links into environmental section (land cover) (IMAGE & AIM*)
Environmental:	GHG emissions (IMAGE & AIM*) Pollution related – particulate matter (pm25) (FAST – under IMAGE) Biodiversity (MSA) (IMAGE – maker model GLOBIO) (Lazlo must disaggregate and send)
Energy:	Secondary energy by source (electricity mix) (IMAGE & AIM*) Final energy demand by sector (IMAGE & AIM*)
Waste:	Material footprint (GTEM) Material productivity (also linked to economic section) (GTEM) Waste to landfill (GTEM) Circularity rate (amount of recovered material) (GTEM)

* AIM provides the model output data for the REF scenario & IMAGE provides the model output data for the Technology-focused and Behaviour-focused Transformation Scenarios.

20 Regional Dimensions of the Transformative Solutions for the Global Environmental Crises

Overall Coordinating Lead Authors: Lindsay Beevers (The University of Edinburgh), Madhav Bahadur Karki (Centre for Green Economy Development, Nepal)

General Contributing Authors: Edward Byers (IIASA), Jianguo Liu (Michigan State University)

AFRICA AND SUBREGIONS

Coordinating Lead Authors: Monday Businge (University of Nairobi), Rachid Mrabet (National Institute of Agricultural Research, Morocco)

Lead Authors: Aliyu Salisu Barau (Bayero University Kano; Urban Climate Change Research Network), Souhila Boulouta (National Economic Social and Environmental Council), Veronica Mwangi (University of Nairobi), William Armand Mala (Department of Plant Biology, University of Yaoundé I, Cameroon)

Contributing Author: Tanya Brodie Rudolph (University of Stellenbosch)

Fellows: Jan Matuštík (University of Chemistry and Technology Prague), Sènankpon Tcheton (Global Change Institute of the University of the Witwatersrand)

ASIA AND THE PACIFIC AND SUBREGIONS

Coordinating Lead Authors: Meena Bohara (National Young Academy of Nepal, Forest Action Nepal), Gensuo Jia (Chinese Academy of Sciences)

Lead Authors: Sanchit Saran Agarwal (The Energy and Resources Institute), Kalpana Chaudhari (Shah and anchor Kutchhi engineering college, institute for sustainable development and research (ISDR) , India), Hancheng Dai (Peking University), Fangxia Shen (Beihang University), Jinlong Liu (Renmin university of China)

Contributing Authors: Shaneel Chandra (Central Queensland University), Leila Zamani (Department of Environment of Iran), Kejun Jiang (Hong Kong University of Science and Technology), Jiayi Ng (Agency for Science, Technology and Research)

Fellow: Ruijun Chen (Fuzhou University, China)

EASTERN EUROPE AND SUBREGIONS

Coordinating Lead Authors: Kateřina Černý Pixová (Czech University of Life Sciences Prague), George Florin Staicu (Academy for Economic Studies, Bucharest, Romania)

Lead Authors: Aistė Balžekienė (Kaunas University of Technology, Lithuania), Judit Oláh (John von Neumann University Doctoral School of Management and Business Administration, Hungary; Faculty of Economics and Business, University of Debrecen, Hungary), József Popp (John von Neumann University Doctoral School of Management and Business Administration, Hungary)

Fellow: Jan Matuštík (University of Chemistry and Technology Prague)

LATIN AMERICA AND THE CARIBBEAN AND SUBREGIONS

Coordinating Lead Authors: Donovan Campbell (The University of the West Indies), Gladys Cecilia Hernandez-Pedraza (Centro de Investigaciones de la Economia Mundial)

Lead Authors: Danielle Mendes Thame Denny (University of São Paulo - Research Centre for Greenhouse Gas Innovation and Centre for Carbon Research in Tropical Agriculture), Alma Mendoza-Ponce (National Autonomous University of Mexico (UNAM)), Jean Pierre Ometto (National Institute for Space Research (INPE), Brazil)

Contributing Author: Shaneica Lester (The University of West Indies)

Fellow: Emmanuelle Freitas (Centre for Mineral Technology), Shaneica Lester (The University of West Indies)

WESTERN EUROPE AND OTHERS GROUP AND SUBREGIONS

Coordinating Lead Authors: Barbara Amon (Leibniz Institute for Agricultural Engineering and Bioeconomy), Paul Sutton (University of Denver)

Lead Authors: Peter Edwards (Manaaki Whenua Group, Bioeconomy Science Institute, Wellington, New Zealand), Michele Filippo Fontefrancesco (Università Cattolica del Sacro Cuore), Joana Portugal Pereira (Coppe/ Federal University of Rio de Janeiro and IST/ULisboa), Thomas Thornton (University of Alaska)

Contributing Authors: Alan Feest (University of Bristol), Amy Molotoks (Stockholm Environment Institute, University of York)

Fellow: Amy Molotoks (Stockholm Environment Institute, University of York)

Chapter summary

Credit: ©UNEP

OVERALL MESSAGE: There is an urgent need for regionally specific transformative actions. It is clear from our analysis that continuing the current pathway is undesirable and unsustainable (*well established*).

Human and natural systems around the globe are connected both locally and through distant processes (tele-coupling), such as international trade, migration, foreign investment, and flows of ecosystem services (Chapter 8) {20.9} **The regionally specific transformative pathways provide ways in which transformation can happen across the five interconnected systems for the global regions. As the systems are transformed in an interconnected manner at regional and subregional scales, there is a need to reflect on the global interconnections by examining change in tele-coupling dynamics** (*well established*). {20.9, 20.9.1, 20.9.1.1} **Changing tele-coupling dynamics may reshape the geographic distribution of environment-socioeconomic impacts. To minimize trade-offs, it is crucial to enhance synergies among different regions for global sustainability** (*established but incomplete*). {20.9.1}

A. Economic and financial system transformation

A transformation of financial and economic systems in Africa can support the significant debt crisis across the region where countries are dependent on foreign aid. To accelerate much-needed financial systems reforms, Africa needs to fully unlock the continent's potential by greening and incentivizing finance systems (*established but incomplete*). Developing mechanisms by which both public and private creditors can provide debt relief to African Nations is critical; investment in the green transition is expected to reach US$190 billion and increasing private finance is essential to supplement public contribution, such as through supporting the African Union's Green Recovery Action Plan. African nations can develop partnerships that promote mutual benefit and long-term sustainability rather than resorting to aid that perpetuates a cycle of dependency undermining the goals of development assistance. African demographics show significant youth-dominated regions can become the next frontier for

investment by leveraging the demographic dividend. A strategic and multi-sectoral approach to investment in preserving ecological infrastructure and ecosystem services and the reorientation of revenue streams towards sustainability principles are essential for allocating scarce public and private resources to achieve economic and social-ecological priorities. Economically more-developed economies can be encouraged to support Africa's green investments under the principle of common but differentiated responsibility. {14.5.1; 14.3; 14.6; 20.4.2.4; 20.4.3.4}

The Asia and the Pacific (AP) region can accelerate climate and biodiversity solutions by transforming their financial systems and integrating green finance measures in national budgeting and expenditure processes (*well established*). **It is imperative that an integrated socio-ecological and economic accounting system is developed that links biophysical aspects of ecosystems with human benefits through the concept of ecosystem services. At the same time, regional finance institutions need to undergo major reform, by mainstreaming climate-resilient and nature-positive financing strategies to transform them into environmentally sound financial institutions** (*established but incomplete*). Environmentally sound financial institutions can fund projects and companies that are benefiting the environment. The Asian Development Bank and the Asian Infrastructure Investment Bank can be reformed further to invest in climate-inclusive and green initiatives. These financial institutions can scale-up concessional loans, equity investments, guarantees, capacity-building and investment-advisory services to support green projects, especially in low-income countries across the region. Enhanced Nationally Determined Contribution commitments can be achieved through increased investments in nature-based solutions to protect natural capital, including sustainable management of terrestrial, freshwater and marine ecosystems. {14.3; 14.4; 20.5.2.5; 20.5.3.4}

Financial and economic transformation in the Eastern European (EE) region is diverse and ranges across European Union (EU) candidate/member states and other countries. For EU member states, and candidate and partnership countries, reforms aligning with EU directives and green transition policies can deliver transformations (*established but incomplete*). **Green innovation-based finance and carbon tax measures can boost investments and consumption towards sustainability. Meanwhile, non-EU related countries can implement distinct strategies** (*well established*). Eastern Europe needs targeted policies to unlock green finance and ensure effective deployment across urban and rural systems. Policy innovation should integrate water-smart strategies – such as household metering, pricing signals, and drought-resilient infrastructure – to minimize water demand, especially in agriculture and peri-urban areas. Green infrastructure investments, including blue-green corridors that link wetlands, parks, and stormwater systems, require long-term capital flows and risk-sharing frameworks. To accelerate uptake, financial tools such as green municipal bonds, concessional lending, and EU-aligned sustainability taxonomies must be tailored to local contexts. Equally important are behavioural communication strategies that shift public norms and business practices. Community engagement and transparent governance will be critical in scaling nature-positive infrastructure and achieving a region-wide transition to circular, low-emission economies. {14.5; 20.6.2.2; 20.6.3.2}

Transformative economic and financial reforms are essential for Latin America and the Caribbean (LAC) to avert climate-induced economic losses, currently projected to reach 100 per cent of GDP by 2050, and build a resilient, inclusive future (*well established*). Targeted investments in resilient infrastructure, fiscal realignment, and green finance are critical to mitigating climate risks that disproportionately affect the region, with estimated losses and damages at 83 per cent of regional GDP – far above the global average. Effective market interventions and stronger institutional capacities are vital for equitable economic transitions. Financial resilience requires scaling up instruments such as green bonds, climate risk insurance, community-led green investments, and debt-for-nature swaps. Carbon pricing, green taxation, and emissions trading can incentivize low-carbon development and finance of adaptation initiatives. Public-private partnerships and innovative models, such as sustainability-linked bonds, can mobilize private capital. Sovereign risk pooling and catastrophe bonds are crucial for buffering economic shocks and stabilizing growth. {14.4; 14.5; 20.7.2.4; 20.7.3.4} bonds, climate risk insurance, community-led green investments, and debt-for-nature swaps. Carbon pricing, green taxation, and emissions trading can incentivize low-carbon development and finance of

adaptation initiatives. Public-private partnerships and innovative models, such as sustainability-linked bonds, can mobilize private capital. Sovereign risk pooling and catastrophe bonds are crucial for buffering economic shocks and stabilizing growth. {14.4; 14.5; 20.7.2.4; 20.7.3.4}

Transforming the energy, material, food and environmental systems is impossible without transforming the financial system in the Western European and Others Group (WEOG) region and throughout the world (*well established*). **The WEOG countries represent roughly 10 per cent of the world's population while they own almost 60 per cent of the world's wealth and enjoy more than half of the world's annual income. Consequently, WEOG countries have a responsibility to demonstrate the desired transitions at home and abroad** (*established but incomplete*). Possible solutions include internalizing externalities or getting-prices-right, reducing risks associated with foreign direct investment in the developing world, debt cancellation, and the development and expansion of existing financial tools used for redistribution and investment, such as EU Green Bonds. These can be complemented by green finance or getting-incentives-right. Examples of this include introducing carbon taxes, green taxes and incentivizing the private sector for innovative financing of circular economic measures such as waste-to-energy. Further possibilities include strengthening the role of Government to use subsidies and revenue from taxes as disincentives for certain non-sustainable economic activities, internalization of external costs, and incentives for labelling, certification, and carbon neutrality. {14.3; 14.4; 14.6; 20.8.2.5; 20.8.3.4}).

B. Transformation towards circularity

Africa can simultaneously invest in circular economy infrastructure and technologies and integrate sustainable consumption and waste management practices utilizing the continent's excellent capacity to outpace linear development. Transitioning to responsible and sustainable material consumption, linearity to circularity, for industrial and urban systems requires substantial financial commitments in Africa (*well established*). **Africa's low industrialization and rapid urbanization offer a unique opportunity to leapfrog to circularity by designing out waste and embracing sustainable construction, resource-efficient manufacturing, and material efficiency technologies alongside honouring the 2018 African Ministerial Conference on the Environment pledge to establish concomitant harmonized regional environmental policies** (*established but incomplete*).

Africa generates 180 million tons of waste a year, of which 70 per cent is openly dumped or burned. Sustainable material production and consumption transformations are essential to conserve Africa's finite resources, with demand projected to rise by 150 per cent by 2050. The shift requires considerable investment and policy reforms. States can access multilateral and blended finance by creating conducive regulatory environments. Public awareness drives and education geared at reducing conspicuous consumption can complement technological advancements in material recycling towards circularity. The resulting economic growth, job creation, cost savings, improved efficiency, new market opportunities, and increased resilience are expected to far outweigh the initial challenges. Africa has a special opportunity to implement "extended producer responsibility" and develop this policy approach further towards "ultimate producer responsibility". Ultimate producer responsibility has the potential to be a game-changing policy instrument given the continent's rising consumption, its position as a consumer of used goods from throughout the world, and its aspirations for green industrialization. {15.2.3; 20.4.2.2; 20.4.3.3}

Five out of the ten countries with the highest plastic waste volumes and six out of the ten highest polluted countries in the world are in the AP region. This legacy pollution, high populations, high emissions and low air quality are distributed differentially across the region. Transformation towards circularity is possible with the key requirements of enforceable regulatory frameworks and citizen's participation to manage waste across sectors (*well established*). There is a need for leadership in packaging with innovation, easier recycling, creative solutions, and better garbage collection and landfill management policies. Enabling legal and policy frameworks, alongside financial and accounting frameworks can help eliminate problems such as single use plastic bags. A mix of regulatory measures, good-practice-based advocacy, knowledge and awareness building for behavioural change can help make a substantial shift in personal and organizational actions. The progress under transformation pathways will be slow initially but is projected to increase by 2030 supported by reducing material demand. {15.2; 20.5.2.4; 20.5.3.3}

By transitioning from managing waste to designing out waste and designing in circularity, the EE region can move towards a circularity transformation and address legacy pollution challenges arising from mining and the ongoing war in Ukraine (*established but incomplete*). This will require binding targets on waste reduction and material recycling, which currently only exist in the sector covering municipal waste and construction and demolition waste, but will be introduced in other sectors as currently material circularity rates are lower than most other European countries (well established). Policy measures may focus on preventing e-waste and stimulate the related e-waste collection and recycling rate and on promoting sustainable production and consumption, coupled with lifestyle change to reduce overconsumption, thus lowering material footprints. These efforts should include reversing the decline of traditional repair shops – such as watch repair, cobbler services, electronics, and home appliance repairs – coupled with the new societal practices of circular lifestyle choices. {15.2.5; 20.6.2.3; 20.6.3.3}

A transformative shift towards circularity in LAC by 2050 requires targeted actions that drive resource efficiency, waste reduction, and sustainable growth, particularly in addressing marine pollution and plastics (*well established*). Strengthening regulatory frameworks and market-based incentives can accelerate circular practices across industries, including biogas generation through anaerobic digestion, regenerative agriculture, and closed-loop manufacturing. Deploying smart waste management systems, such as real-time tracking and automated sorting, can optimize resource flows and minimize leakage into the environment. Modernizing municipal waste systems through public-private partnerships and sustainability financing can improve collection and recycling in underserved areas. Expanding circular business models and building skilled workforces through reskilling programs are crucial for sustainable economic growth and resilient supply chains. {15.3; 20.7.2.3; 20.7.3.3}.

The WEOG countries can address transforming material and waste management systems to circularity through the reallocation of existing resources. The three primary levers of control for transformation in WEOG are implementation of circularity principles, eliminating planned outdatedness, and increasing eco-taxation (*well established*). The shift towards green consumerism through prioritizing sustainable eco-friendly products and services can be supported by digital tools such as community platforms and by new regulatory oversight of advertising messages and emerging market reforms to support the sharing economy. Similarly, behaviour change can be achieved with financial incentives such as eco-taxation to support a shift towards sustainable lifestyles that prioritize quality over quantity, As well, sharing and reductions in material consumption should be supported. {15.2.2; 20.8.2.3}

C. Energy system transformation

By taking a holistic, integrated and Africa-led approach to addressing both the supply and demand sides of energy, the continent can achieve universal energy access, drive sustainable economic growth, and play a global leadership role in the clean and just energy transition. Africa can transform the primary energy system while simultaneously increasing access to energy at the household level, through rural electrification drives, connecting households to national and decentralized grids and increasing the overall share of renewables enhancing the existing hydropower provision and embracing solar, wind and geothermal technologies (*well established*). With 13 per cent of the world's hydropower potential, Africa can use its available water resources, such as the Congo River Basin, to realize its hydropower potential and scale-up clean-energy provision. To address inequitable energy access in Africa, aggressive rural electrification and decentralized grids can be delivered through new wind and solar technology, alongside a just transition to modern clean cooking fuels at the household level. Financial incentives through repurposed subsidies can support this transition alongside raising awareness, aligning with evolving pro-environmental consumer values,, providing sustainable mobility choices such as mass rapid transit systems, and enforcing responsibility through taxation, underpinned by sound governance. {16.2.1; 16.2.2; 16.3.3; 16.4.2; 20.4.2.1; 20.4.3.1}

Regionally diverse and with the largest energy use, driven by increased consumption especially from emerging economies, Asia and the Pacific region is expected to increase its share of the global energy demand by 2050. The region can achieve a transformation to meet universal electricity access

by 2050, with financial system support, through regionally appropriate renewable energy deployment, increased energy access, rural electrification and decentralized grids, and electrification of transport systems (*well established*). Most AP countries can embrace solar and wind technologies, increasing the market to 38 per cent by 2050 (**Figure 20.6**). The Pacific Island countries can promote floating solar off-grid solutions, while there is high potential for wind and solar energy production in West Asia. Grid infrastructure strengthening with associated policy reform is necessary to support hydrogen and biofuel energy in emerging economies. Electrification of the transport system, especially in large urban conurbations, alongside financial incentives through taxation of large vehicles. Private sector involvement in financial policies and regulation is required, alongside demand side measures driven by lifestyle changes and market reforms. {16.2.1.; 16.3.2; 16.3.3; 20.5.2.1; 20.5.3.1}

Eastern Europe depends heavily on fossil fuels, however by 2050 a low-emission, green economy is possible through following similar pathways as pursued by the EU. This entails embracing renewable energy through repurposing financial subsidies, developing a cross-border carbon adjustment mechanism, breaking monopolies, and enforcing stronger regulation of energy markets (*well established*). To improve the environment and public health, particularly air quality, and to reduce energy poverty, EE can increase the renewable share through policy incentives such as decentralized green energy production and support civic energy to break state monopolies through establishing energy communities. As well, repurposing subsidies, such as EU Social Climate Fund and ETS revenues, can lower energy bills, promote clean transport, and invest in energy-efficient housing. These changes can be supported by awareness-raising about lower energy lifestyles, mechanisms to finance renewable and efficient energy infrastructure at the household level, and sustainable mobility options. {16.3.2; 16.2.3; 16.3.3; 20.6.2.4; 20.6.3.4}

Resilient decarbonization through smart electrification and microgrids is essential for sustainable energy transformation in LAC by 2050 (*well established*). Electricity demand is expected to increase significantly under both behaviour and technology-focused pathways, highlighting the need for decentralized energy systems that enhance disaster resilience, expand rural access, and support renewable integration. Abundant wind, solar, and bioenergy resources can complement existing hydropower, reducing water stress. Regional cooperation is crucial to fund clean energy projects like offshore floating photovoltaics and wind installations, minimizing land-use changes. In the Caribbean, transitioning to wind and solar could cut fuel imports by 70 per cent and reduce fossil fuel dependence by 60 per cent by 2050. Community-shared energy facilities – such as micro hydro, solar home systems, and off-grid mini-grids – could electrify 20 million underserved rural residents. {16.2.1; 16.2.3; 20.7.3.1}

The WEOG countries have a long legacy of mineral and fossil fuel extraction, therefore, they can achieve rapid decarbonization through transitioning to renewable energy, enhancing energy efficiency, reducing energy consumption, and supporting electricity-based transportation. As well, WEOG countries can refine and demonstrate carbon dioxide removal strategies. Three primary actions for transformation are ending fossil fuel subsidies, large-scale implementation of smart grids and efficiency gains in both consumption and production of energy (*well established*). Carbon capture and storage and bioenergy with carbon capture and storage technology are projected to rise by 2050. However, this projection is based on currently unachieved scientific and technological innovations. Reductions in energy use can be supported through low-energy consumption principles at both industry and household level, alongside a move to collective community action adopting domestic energy production by 2050. {16.2.2; 16.2.3; 16.3.3; 20.8.2.1; 20.8.3.1}

D. Transformation of food systems

To address food security and undernourishment, with 286 million undernourished population in 2020, Africa can transform the food systems taking a holistic approach that prioritizes sustainability, equity and the integration of Indigenous Knowledge and Local Knowledge processes with modern technologies (*well established*). In other terms, by systematically addressing interconnected dimensions of food security, environment sustainability and social harmony, Africa can build resilient, equitable, and sustainable food systems that not only feed

its population but also nurture its environment and foster lasting peace. Dietary change in Africa can be achieved through leveraging indigenous cultivar and culinary diversity and commercially producing protein-rich food sources and encouraging using all part of a plant to reduce waste, which can improve food security in low-income communities. By strategically integrating transhumance and stable livestock farming, Africa can transform its livestock sector into a more productive, resilient, and environmentally sustainable system, contributing significantly to food security and rural development, particularly in the Sahel and East Africa. Inclusive governance, conservation-based agriculture intensification, and agroecological innovation can deliver stable and quality food production while strengthening energy, food, and nutrition security and reducing poverty, thereby improving the resilience and health security of vulnerable communities. {17.2.1; 17.2.3; 17.2.4; 20.4.3.2}.

To address food security and nutritional food demand, food system transformation in the Asia and the Pacific region is critical due to increasing demand and supply gap, unsustainable production practices, rapid population growth and urban expansion. Transformation can be achieved through a shift to sustainable diets, including Indigenous and local food systems and production of novel foods. An important component is countering the rise in meat and dairy consumption among AP's growing middle class, by rearing regionally appropriate livestock on pasture, supporting the growing vegetarian and vegan movement and connecting small-scale farmers with supermarkets through government support or private finance (*established but incomplete*). Reducing food loss and reusing food waste for nutrient recovery through backyard composting in rural towns can reduce pressure on land degradation. Specific to AP is the potential for aquaculture to remain a global strength, with 92 per cent of the global market in farmed fish. Sustainable aquaculture must be supported through governance reform to curb overfishing and promote responsible intensification by redirecting subsidies into upgrading the value chain. {17.2.5; 17.2.3; 20.5.2.2; 20.5.3.2}

Eastern Europe is a crucial contributor to global food security, currently producing 22 per cent of the world's wheat. Achieving food system transformation must address land degradation and rural depopulation. Transformation can occur through shifting to a sustainable diet of plant-based food, improving health outcomes. This shift will drive an 11 per cent increase in demand for food crops by 2050, supported by a 41 per cent increase in agricultural productivity by 2050 if precision farming and waste reduction strategies are embraced (*well established*). Eastern Europe's agricultural sector is poised to remain a cornerstone of regional GDP, offering both economic stability and a safety net through resilient small-scale farming. Empowering these producers with access to land, finance, and markets can safeguard food sovereignty and rural livelihoods. Dietary shifts away from livestock-based diets – potentially reducing crop demand for feed by up to 49 per cent – can lower land-use intensity and soil degradation. This transition must be supported by policies that promote nutrient-rich, plant-based diets and encourage food literacy through schools and community programmes. Eastern Europe can leverage its long-standing tradition of community-based food systems – such as cooperative farming, local markets, and household gardens – to advance circularity, nutrition security, and climate-smart agriculture. Integrated policy support linking agroecology, sustainable consumption, and low-impact production will be essential to address environmental pressures while ensuring inclusive economic opportunities across urban and rural communities. {17.2.1; 17.2.5; 20.6.2.5; 20.6.3.5}

Achieving a just and resilient food system transformation in LAC by 2050 requires targeted support for smallholders and Indigenous communities, alongside climate-adaptive agricultural practices that restore ecosystems and enhance food security (*well established*). Prioritizing agroecology, secure land tenure, and healthy diets can drive forest recovery and biodiversity gains. The behaviour-focused pathway envisions a 46 per cent reduction in agricultural land by 2050, while the technology-focused pathway anticipates a 50 per cent increase in livestock and cropland, risking ecological harm. Sustainable food production strategies include urban agriculture in the Caribbean, precision farming in Central America, and no-deforestation supply chains in South America. These shifts can reduce water demand by 12 per cent, nutrient run-off by 20 per cent, and malnutrition by 98 per cent, while improving calorie distribution by 58 per cent. Financial mechanisms, regional cooperation, and inclusive policies that consider

gender, rural and low-income populations, are essential for equitable and sustainable food systems. {17.2.2; 17.2.3; 20.7.2.2; 20.7.3.2}.

The WEOG region currently produces 30 per cent of the global food supply. The transformation to sustainable food production – threatened by climate-induced heat, flooding and drought – is possible by shifting to more plant-based diets potentially supplemented by new products and markets (*well established*)**.** The three primary actions for transforming the food system in WEOG are promoting sustainable agricultural practices and food production systems, including Indigenous practices that support food sovereignty, circular economies, and well-being; optimizing logistics for food value chains to reduce food waste; and shifting towards plant-dominated diets (well established). To support a just transition, the promotion of ecologically sound agriculture intensification and customized technological interventions should be prioritized to achieve sustainable farming practices. These efforts can be bolstered by advancements in precision farming and developments in plant and livestock breeding. Reducing food waste is essential. {17.2.4; 17.2.5; 20.8.2.2; 20.8.3.2}

E. Environmental System Transformation

Environmental sustainability in Africa is crucial, given the continent's immense biodiversity, vulnerability to climate change, reliance on natural resources for livelihoods, and rapid population growth and urbanization. Transformative nature-positive and climate-adaptive actions can slow down the 1.4 million km^2 of land degraded and reverse deforestation trends, such as the 20 per cent decrease in vegetation cover experienced in the East African Highlands (*well established*). Africa's diverse ecosystems offer significant opportunities for sustainable conservation, ecosystem-based adaptation and carbon sequestration. To maximize this potential, initiatives like REDD+ that support green value chains, payment for ecosystem services, and community-based forest management can promote sustainable land use and forest conservation. These efforts, supported by funding from the Green Climate Fund and other financial institutions, can capture the carbon value of well-managed forests and agricultural lands. Promoting carbon-neutral energy, climate-resilient agriculture, and nature-positive investments can help policymakers reduce greenhouse gas emissions and address land-use damages like nutrient depletion, salinity and erosion, with high-emitting countries providing the requisite financial support, technology transfer, and capacity-building assistance through multilateral financial institutions. Integrating Indigenous Knowledge with scientific practices can further enhance sustainable land management, reduce deforestation, and strengthen climate resilience. Africa can genuinely transform its financial system to become a potent force for biodiversity preservation and climate action – unleashing its vast natural wealth for sustainable development – by concurrently bringing capital into the system and guaranteeing a strong pipeline of investable green projects. {18.2.1; 18.2.4; 20.4.2.3; 20.4.3.5}.

Strengthening regional cooperation in the AP region is vital to achieve transformative solutions through knowledge-sharing, technology transfer, and international partnership (*well established*). Adopting green innovation with integrated technology alongside lifestyle change can support environmental transformation. Regional and transboundary cooperation can lead to sustainable conservation, strengthening synergies between climate and biodiversity actions at landscape and seascape levels. Prioritizing technological innovation and energy efficiency emerge as key strategies tightly connected to emission reduction and playing vital roles in ecological management. Growing numbers of nature-based solutions pilot cases offer insights for potential adoption in the Pacific Small Island States. Ecosystem-based adaptation is widely recognized in the AP regions as sustainable approaches to climate change adaptation. Integrating climate-resilient agroforestry, sustainable forest management, and conservation agriculture practices using Indigenous and local knowledge can improve ecological integrity of both agriculture and forest ecosystems. {18.2.1; 18.2.3; 20.5.2.3; 20.5.3.5}

Although numerous sites in EE have legacy pollution issues and require revitalization, a transformation towards a resilient environmental system is possible. A shift towards sustainable diets promoted by a food system transformation will drive the adoption of precision farming, regenerative agriculture, organic farming and sustainable forestry, leading to improved soil health and reduced chemical inputs and promoting a healthier ecosystem (*well established*). Nature-based infrastructure and sustainable

production techniques can drive transformative environmental outcomes in Eastern Europe. Although the region hosts many protected areas, most suffer from poor management, weak enforcement, and fragmented ecological networks – undermining their effectiveness as biodiversity and climate buffers. Addressing land degradation will require investing in connectivity across green corridors, riparian zones, and rewilded landscapes, alongside integrated watershed management to enhance ecosystem services and water security. Nature-based solutions, such as wetland restoration, agroforestry buffers, and reforestation, must be embedded in spatial planning and regional investment strategies. However, weak environmental activism at both individual and community levels hinders behavioural transformation. {18.2.1;18.2.2; 20.6.2.6; 20.6.3.6}

Transforming environmental systems and reversing biodiversity loss by 2050 in LAC requires large-scale nature-based solutions supported by green finance and regional cooperation (*well established*). Achieving net-negative emissions through a 50 per cent reduction in CO_2, a 16 per cent expansion in forest cover, and a five gigaton gain in carbon stocks demands large-scale reforestation, regenerative agriculture, and afforestation over 190-296 million hectares. Restoring mangroves, seagrasses, and coral reefs can enhance blue carbon storage and protect coastlines. Indigenous-led stewardship, backed by policy frameworks that secure land rights and fund ecological knowledge, is crucial. Green urban infrastructure, satellite monitoring, and circular economy strategies in agriculture and construction can minimize waste and pollution. Financing mechanisms like green bonds and carbon credit markets, alongside regional cooperation in transboundary ecosystems, are essential for scaling nature-based solutions and enhancing community resilience across LAC. {18.2.1; 18.2.2; 20.7.2.5; 20.7.3.5}.

Nature-based solutions including nature-positive climate actions are imperative to address complex and interactive environmental effects in the WEOG region (*well established*). **Improvement in environmental stewardship can be achieved through establishing global monitoring of ecosystem function, developing integrated economic and environmental accounting, and enhancing natural and technical carbon sequestration** (*well established*). Countries of the WEOG, by transforming their financial systems, can lead by example, inspiring other regions to adopt similar practices. The positive examples in high-income countries can enhance international cooperation on climate initiatives, technology transfer, and sustainable development goals, creating a more robust collective global response to environmental challenges. Shifting to nature-positive diets, reducing food waste, and minimizing postharvest loss can decrease the land required for intensive agricultural production and support biodiversity. By reducing consumption and waste, material system changes decrease resource demand and environmental degradation as demonstrated by Indigenous Peoples' traditional circularity practices {18.2.3; 18.2.4; 20.8.2.4; 20.8.3.5} can enhance international cooperation on climate initiatives, technology transfer, and sustainable development goals, creating a more robust collective global response to environmental challenges. Shifting to nature-positive diets, reducing food waste and minimizing postharvest loss can decrease the area needed for agriculture, reducing biodiversity loss. By reducing consumption and waste, material system changes decrease resource demand and environmental degradation as demonstrated by Indigenous Peoples' traditional circularity practices {18.2.3; 18.2.4; 20.8.2.4; 20.8.3.5}.

20.1 Introduction

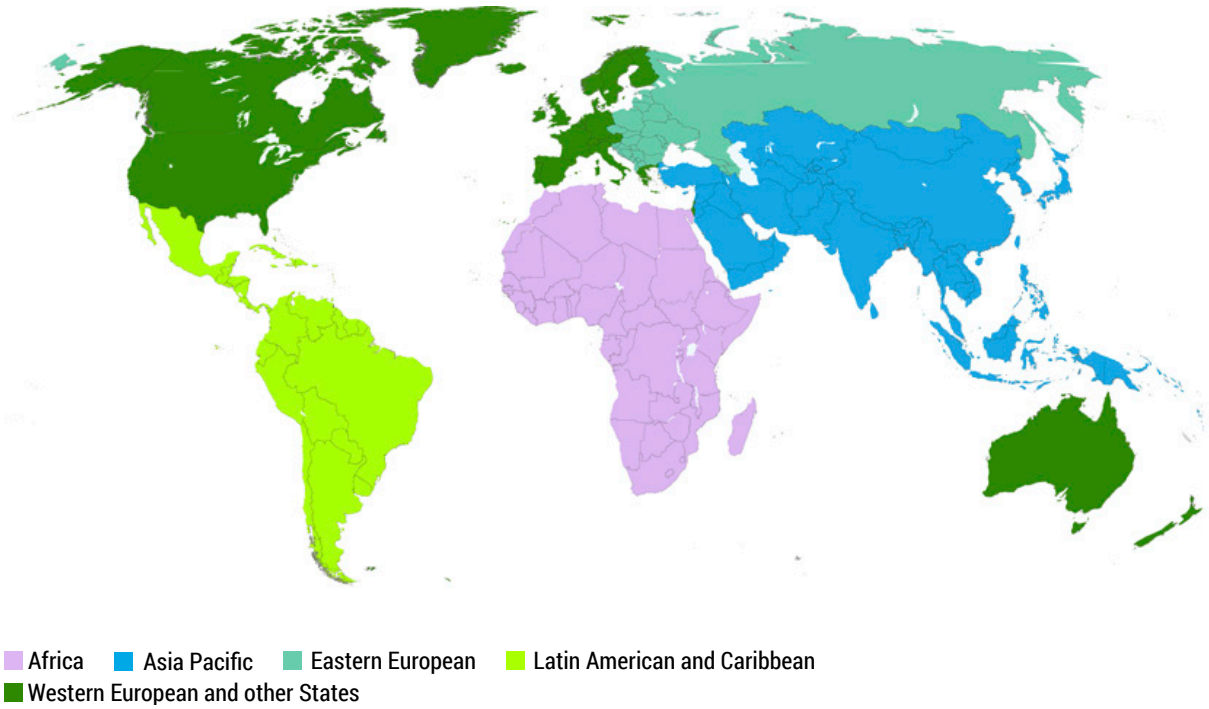
This chapter presents plausible and potential future outlooks for the five United Nations regions in the face of three global environmental crises that are formally defined as the crisis of climate change, the crisis of biodiversity loss, land degradation and desertification, and the crisis of pollution and waste. The future outlooks for the United Nations regions are assuming the effective implementation of transformative pathways (Chapters 9-11). This chapter focuses on responding to the policy questions below and discusses how the transformations of five systems – economic and financial, energy, food, materials, and environmental – can happen:

1. How does policy development and implementation in one region affect other regions or other countries, and what is needed to maximize positive and minimize negative effects?

2. How could the interrelationships of the environmental issues and the energy, food, materials/waste systems change in the future, and what pathways and scenarios could lead to environmentally sustainable futures, building on synergies, while minimizing unintended consequences?

3. Can the internationally agreed environmental goals be met? How are the socioeconomic impacts of the system transformation distributed differently across countries at different socioeconomic development trajectories and climate vulnerability?

4. How can countries address uneven or skewed effects of these socioeconomic impacts?



The Chapter responds to the above policy questions in a consolidated manner covering all the five United Nations regions by disaggregating the global modelling results from the previous chapters and explores regionally differentiated transformation pathways. The chapter outlines potential trajectories in which the transformation can occur.

20.2 Approach

Chapter 20 presents the regional outlooks across five United Nations-defined regions (**Figure 20.1**):

- Africa
- Asia and the Pacific [AP]
- Eastern Europe [EE]
- Latin America and the Caribbean [LAC]
- Western Europe and Other Group [WEOG]

Figure 20.1: Regional groups of UN Member States

It takes as its starting point the environmental priorities highlighted in Chapter 8 (**Table 20.1**) and focuses on analysing regional similarities and differences in the implications of two different pathways. Available literature evidence (IEA 2023; UNEP 2023; UNECS 2024a), makes it clear that developed and developing countries will follow different pathways to tackle the global environmental crises (Desai 2022). These pathways represent a spectrum of future possibilities through which transformation can happen.

Two different transformation scenarios have been designed: the *GEO-7 Behaviour-focused Transformation Scenario and the GEO-7 Technology-focused Transformation Scenario* (Chapter 11) that yield the various transformation pathways explored. The disaggregated modelling outputs are used in conjunction with the region-specific actions identified in the solution pathway chapters (Chapters 14-18) and in combination with peer-reviewed literature, including Indigenous Knowledge and Local Knowledge perspectives, to provide contextual narratives on regional trajectories and subregional differences, as well as interlinkages.

Finally, the chapter synthesizes findings across the systems and future pathways, using the types of policy and regulatory solutions identified as effective in earlier chapters (Chapters 14-18) to draw conclusions on potential future transformation. Synergies and trade-offs between regions are then explored, reflecting the tele-coupled socioeconomic and environmental interactions over distances, as presented in Chapter 8 (**Figure 20.1**).

20.3 The GEO-7 Current Trends Scenario is not a Future Option

Results from the Intergovernmental Panel on Climate Change (IPCC) AR6 indicate that the climate implications of continuing along the current path have significant adverse environmental consequences (IPCC 2023). There are notable regional differences in the impacts of climate change, which are unequally distributed across the United Nations regions, resulting in each region having a distinct future trajectory.

Exploring the regional implications of maintaining current policies and practices across all regions suggests that there are significant drawbacks to staying on this path, as reflected by the regional disaggregation of Chapter 10 findings. This *GEO-7 Current Trends Scenario* is used to assess the environmental and socioeconomic implications if global environmental crises are not addressed.

The African region is expected to face severe and widespread consequences from climate change, including extreme weather events such as droughts and intense heatwaves. West and Sub-Saharan subregions are expected to face extreme food and water insecurity due to climate change (IPCC 2023). This insecurity will have catastrophic effects on the agriculture and livestock sectors due to severe flood events as well as the expected droughts (IPCC 2023). Land degradation and desertification are expected to accelerate in North Africa and the Sahel, resulting

Table 20.1: Regional environmental priorities identified in Chapter 8

Region	Priorities
Africa	Unsustainable resource exploitation and use Ecosystem degradation and ecological vulnerability Climate change vulnerability with escalating extreme events
Asia and the Pacific (AP)	Climate change impacts on development and cultural heritage Land-use change impacts on ecosystems Pollution and waste impacts on ecosystems and human health
Eastern Europe (EE)	Loss of ecosystem services due to unsustainable agriculture Unsustainable energy system effects on climate and health Biodiversity loss due to weak management frameworks
Latin America and Caribbean (LAC)	Changes in land-cover dynamics Changes in freshwater quality and availability Degradation of coastal and marine resources
Western Europe and Others Group (WEOG)	Biodiversity loss and ecosystem change Climate extreme events Pollution and waste

in a reduction of arable land and exacerbating food insecurity. The loss of livelihood resources leads to increased vulnerability, characterized by widespread poverty, governance challenges, and a lack of social safety nets, suggesting displaced communities will emerge and there will be an increase in cross-border migration. Loss of biodiversity and worsening air, water, and land pollution are expected to further increase food and water scarcity, as well as spur diseases like malaria. Biodiversity loss, particularly of wildlife, and ecosystem collapse will threaten livelihoods and lead to further food and resource scarcity. Fishing industries in West and East Africa are expected to collapse due to coral bleaching and the degradation of coastal ecosystems. The consequences of uncontrolled industrialization and urbanization on air, water and land pollution will be significant (World Bank 2024).

For the Asia and the Pacific region, staying on the current trend threatens any chance of achieving the sustainable development goals (SDGs). Continued global warming will increase the frequency and intensity of heatwaves, floods, droughts, and cyclones, impeding food production in South and Southeast Asia. Sea level rise is expected to endanger many of the region's island states and coastal cities by 2050 (IPCC 2023). Coastal fisheries and ecotourism businesses are expected to suffer severe losses. Approximately 2 billion people are expected to face significant water shortages due to the rapid and unseasonable melting of Himalayan glaciers (IPCC 2023). Repercussions for human health due to the combined effects of climate extremes and rising pollution are expected to be severe. Vector-borne diseases, including malaria and dengue, are expected to rise. The current model of industrialization, urbanization and resource exploitation will further erode biodiversity and nature's resilience in the region (UNDP 2022).

For the Eastern European region, the results from the *GEO-7 Current Trends Scenario* show increasing pressures from climate change on environmental systems. These pressures threaten biologically valuable areas that currently lack any protection status. Significant increases are expected in the frequency and intensity of extreme precipitation events, and with this increase comes an associated increase in natural hazards such as flooding and landslides.

In Latin America and the Caribbean, the Current Trends pathway will have significant implications for human and natural systems. Consequences for biodiversity and human systems are expected to escalate due to an increase in the frequency and intensity of extreme heatwaves and droughts. Those effects, exacerbated by extreme flood events, will put heightened stress on water resources, with serious consequences for fisheries and agriculture.

Across the non-contiguous region of Western Europe and Other Groups, continuing on the Current Trends pathway has significant implications for both environmental and human systems. The cost of no transformation will lead to significant biodiversity loss across large parts of North America, continental northern Europe and parts of Australia. Water resources are likely to be significantly altered, with North America and Northern Europe experiencing increased precipitation frequency and intensity. At the same time, Australia and southern Europe are expected to face an increase in the severity of droughts and heatwaves. Socioeconomic problems are anticipated to result from environmental deterioration in the WEOG region.

20.4 Africa Region

20.4.1 Introduction

This section outlines policy and development options to reverse Africa's key environmental challenges highlighted in Chapter 8:

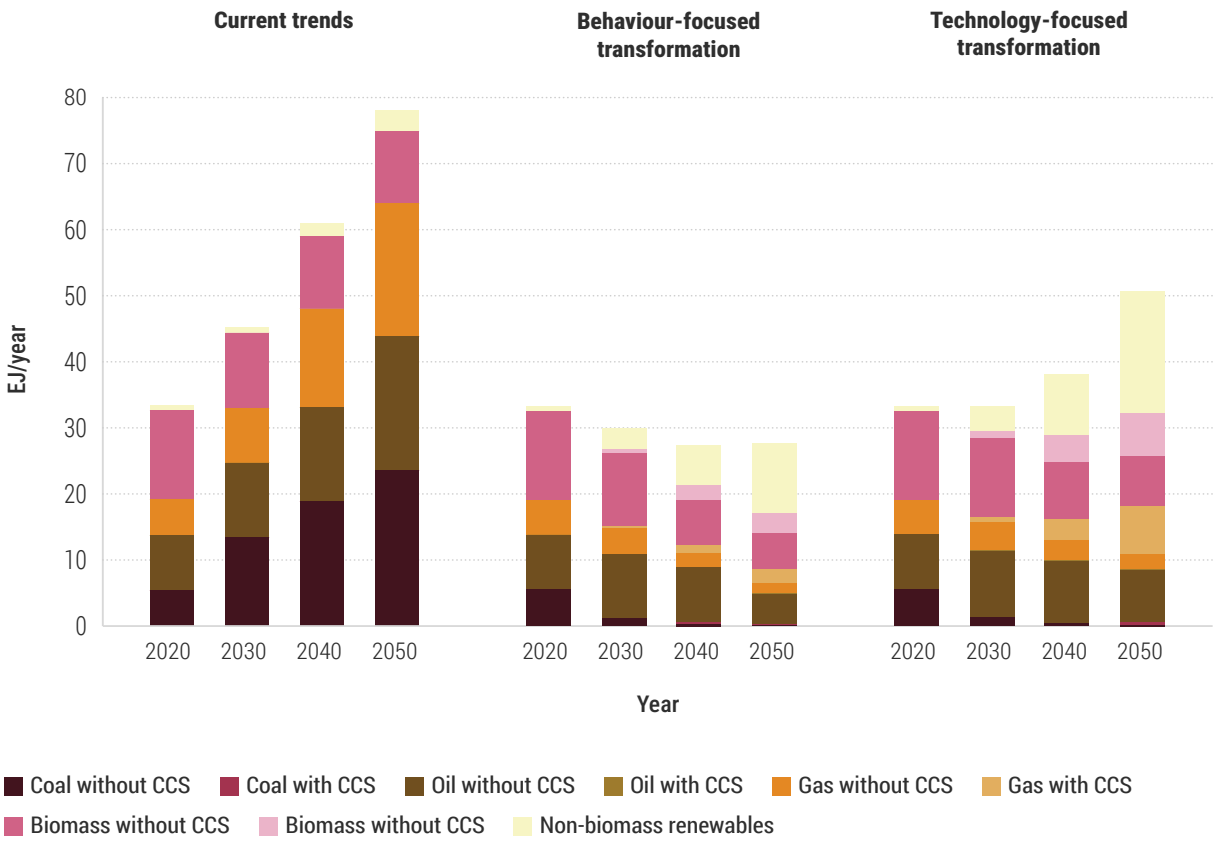
- Ecosystem degradation and biological vulnerability
- Unsustainable exploitation and use of natural resources
- Climate change vulnerability and extreme events

Addressing these environmental priorities is crucial for sustainable resource management, climate resilience, disaster preparedness, and positioning Africa as a leader in environmental sustainability, thereby promoting public health and strengthening social equity, livelihood and economic growth.. This section considers

the practicality and implications of addressing the above priorities by implementing intrinsically interdependent Technology-focused and Behaviour-focused transformations in Africa's energy, food, materials/waste, economic and financial/environmental systems to make them more sustainable and resilient with co-benefits from improved human health and well-being. Transformation of the energy system would enhance energy access, quality and security (IEA 2022) through an increased uptake of renewable energies such as solar photovoltaic, hydro, wind, geothermal and green hydrogen, an adoption of decentralized smart grids, and a shift to sustainable consumption behaviours. Transforming the food system through ecological intensification and technological advancements would enhance food security, food sovereignty and ecosystem health, while promoting culinary diversity and incorporating protein-rich, overlooked, indigenous foods. Entrenching circularity in the materials and waste system would help address pollution and overconsumption of the region's natural resources (FAO 2019; FAO 2023). Transforming the economic and financial systems would shift resources to sustainable businesses. Restructuring the environmental system through stringent regulations and the adoption of renewable energy, for example, can halt and reverse biodiversity loss and ecosystem destruction, as well as reduce emissions. Incorporating the perspectives offered by Indigenous Knowledge and Local Knowledge into the design of policy and strategy for all five systems, as well as their implementation and monitoring, will better ensure cultural relevance and acceptability, environmental sustainability, resilience, cost-effectiveness, and social justice and equity (UN 2023).

Although the desired outcomes are admittedly ambitious, they can be unlocked by integrating public participation, implementing governance reforms and streamlining financial systems. These can be promoted on a regional level by leveraging the flagship projects of the African Union Agenda 2063 – such as the formulation of a regional sustainable trading strategy, the strengthening of continental financial institutions and the implementation of the African Continental Free Trade Area (AfCFTA) – to develop and harmonize common regulatory frameworks that minimize negative environmental externalities and promote sustainable environmental practices across the member states (AUC 2018; Quartey 2023).

20.4.2 Technology-focused Transformation Pathway



This pathway emphasizes regionally tailored, technology-driven solutions to drive systemic change across energy, agriculture, and materials sectors through transformative, integrative, and cross-sector approaches.

20.4.2.1 Transition to renewable energy

Africa has substantial opportunities to leverage the global net-zero transition (Ngondieb et al. 2020; Mutezo and Mulopo 2021; Blimpo et al. 2024) to significantly stimulate green growth and enhance public health (Maupin 2017). The Congo River basin management, for example, can mitigate the loss of arable lands and forests, thereby reducing food insecurity (Olson and Omoyajowo 2025). Integrated management of the Congo River basin can make Africa a leader in clean energy production (IEA 2020). However, addressing the increasing flood and drought scenarios in the basin will be a challenge.

Aggressive large-scale rural electrification drives that connect rural households to national or decentralized grids incentivize the adoption of energy efficiency and the transition to renewable energy. This can play a crucial role in socioeconomic development of Africa, as it can improve living standards (Deutch 2020; Cotterman et al. 2021) and achieve energy self-sufficiency (Acheampong et al. 2019; Hafner et al. 2021; Manjong et al. 2021) and security (Kouton 2021). While the region can achieve SDG 7 by 2030 (International Renewable Energy Agency [IRENA] 2021), meeting this and the Paris Agreement aspirations will require profound energy and land-use policy shifts. These shifts will encourage the integration and adoption of renewable energies, the development of necessary infrastructure for hydro, solar, geothermal and wind mini-grids, and the sustainable utilization of reserves of cobalt, lithium, manganese, and platinum that are essential inputs to renewable technologies. The deployment of solar photovoltaic, wind power, and clean-cooking solutions will tap into the region's vast renewable energy potential and protect forest ecosystems (Renewable Accelerator for Innovative and Sustainable Energy in Africa [RES4Africa] 2023) and reduce air pollution, thereby improving public health and the overall quality of life.

Figure 20.2: Increased uptake of renewable energies

The share of renewables in the primary energy mix will gradually increase to become the dominant energy source by 2050 (**Figure 20.2**). Total energy demand is projected to surpass 3100 terawatt-hours by 2040 (Nel and de Kock 2021), with installed capacity increasing by 700 gigawatts. Long-term sustainability will depend on ensuring a just energy transition that benefits the historically marginalized (Nwokolo et al. 2023) and is underpinned by sound governance (IRENA 2021). Looking towards 2040, Africa could focus on diversifying its renewable energy mix by investing in high-capacity energy storage technologies such as batteries and pumped-storage hydropower.

According to Peters et al. (2024), 76 per cent (1,225 TWh) of the estimated 1,614 terawatt-hours of electricity needs for 2040 could be met by renewable energy sources if all current wind, solar, and hydropower plants run at full capacity and all proposed plants are put into operation (82 per cent hydropower, 11 per cent solar power, and seven per cent wind power). Although hydropower has been the primary renewable energy resource up to this point, solar photovoltaic and wind turbines have the potential to lead sustainable renewable energy pathways in the future while simultaneously safeguarding freshwater ecosystems due to their 90 per cent and 60 per cent decrease in costs, respectively, since 2009 and 2010.

Incentivizing the adoption of electric vehicles including bicycles and motorcycles and establishing robust charging infrastructure will reduce Africa's reliance on fossil fuels in the transportation sector, aligning with global decarbonization goals (IEA 2022) (**Figure 20.02**).

Africa could enhance energy security and economic cooperation by establishing regional power interconnections and cross-border power trading to optimize renewable energy use, creating a resilient and integrated energy system (Africa Development Bank [AfDB] 2021). Developing a skilled workforce (UNEP 2022) and integrating renewables with agriculture, water and sanitation, and health care can create synergies to address the interconnected challenges of the global environmental crises which are interlinked with human issues (i.e. hunger and health).

As the global demand for green hydrogen is rising, Africa could benefit from the lack of legacy technologies to harness its estimated 1,590,000 terawatt-hours per year potential (European University Institute 2020). Green hydrogen can help with decarbonization of the energy sector while its amenability to be transported over long distances primes it as the next generation export which can accelerate the attainment of several SDGs particularly in the Northern and Southern Africa subregions which have significant untapped solar photovoltaic and concentrated solar power and wind energy. **Box 20.1** sets out the role of green hydrogen in development, using Namibia as a microcosm for the endowed subregions {16.2.1-16.4.2}.

20.4.2.2 Circular economy, and pollution control and prevention

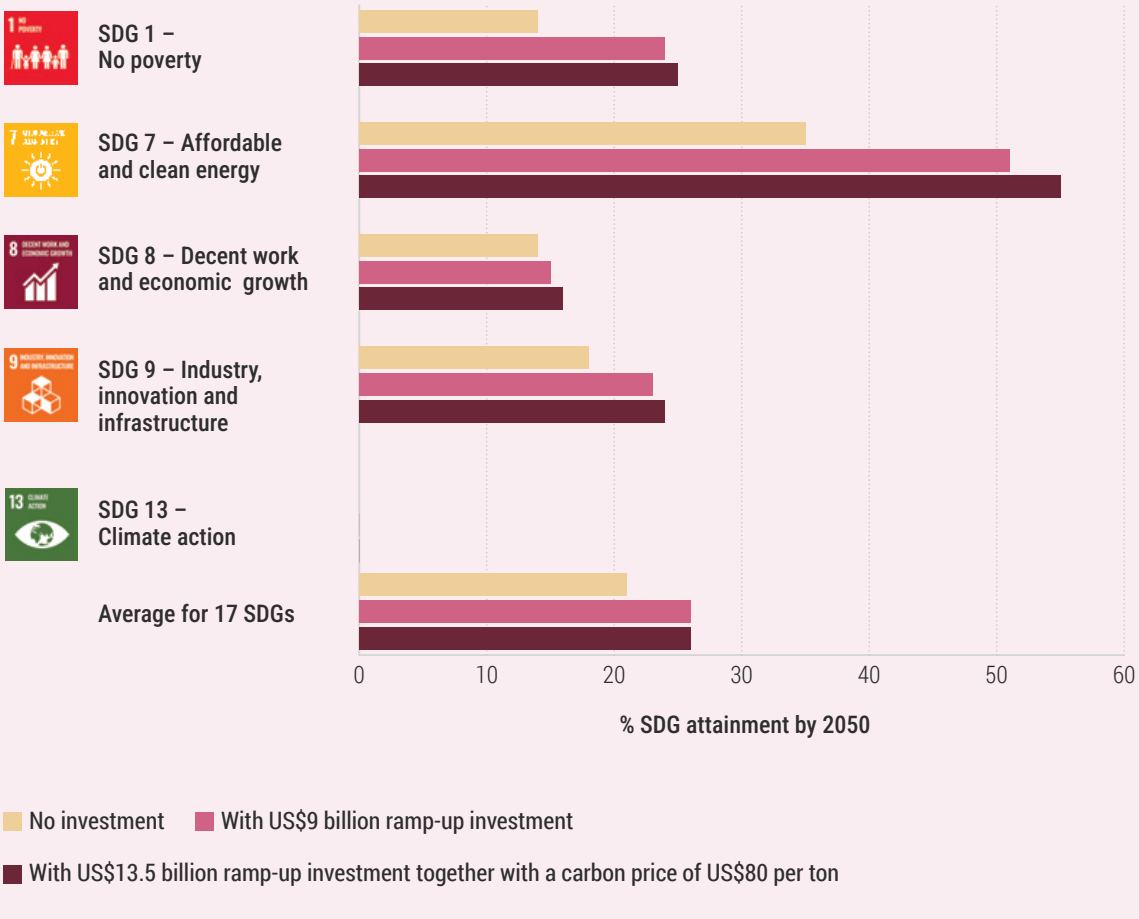
Africa's low industrialization offers a unique opportunity to leapfrog to circularity through sustainable construction, resource-efficient manufacturing, and material efficiency technologies (ECA 2020). Rapid urbanization generates substantial waste, which can be repurposed for energy recovery in the form of electricity, heat, or fuel and soil nutrient recovery. With chemical and cement production projected to rise until 2050, integrating digital technologies, data analytics, and smart urban planning can help address urban challenges (Mamphiswana and Bekele 2020). Africa's regional economic communities can emulate the 2011 polythene ban by the East African Legislative Assembly. Following the publication of the 2018 Africa Waste Management Outlook, the African Ministerial Conference on the Environment pledged to establish concomitant harmonized regional environmental policies. Although the shift requires considerable investment and policy reforms, states can access multilateral and blended finance by creating conducive regulatory environments. The resulting economic growth, job creation, cost savings, improved efficiency, new market opportunities, and increased resilience are expected to far outweigh the initial challenges {15.2.3}.

20.4.2.3 Conservation and Restoration of Nature are crucial for sustainable and resilient food systems

Africa's diverse ecosystems offer significant opportunities for sustainable conservation, ecosystem-based adaptation, and carbon sequestration, with African forests projected to maintain a higher net carbon sink than Amazon forests from 1990 to 2040 (Hubau et al. 2020). To maximize this potential, initiatives like Green Value Chains, REDD+, Payment for Ecosystem Services, and community-based forest management can promote sustainable land use and forest conservation. These efforts, supported by funding from the Green Climate Fund and other financial institutions, can capture the carbon value of well-managed forests and agricultural lands. Additionally, the Taskforce on Nature-related Financial Disclosures provides guidelines for businesses to assess and manage nature-related risks, aligning financial flows with the Kunming-Montreal Global Biodiversity Framework. Integrating Indigenous Knowledge with scientific practices can further enhance sustainable land management, reduce deforestation, and strengthen climate resilience (Nkuba et al. 2020; Nkuba et al. 2023).

Promoting carbon-neutral energy, climate-resilient agriculture, and nature-positive investments can help policymakers reduce GHG emissions and mitigate land-use impacts like salinity and erosion, supporting attainment of Paris Agreement and Kunming-Montreal Global Biodiversity Framework commitments. The IPCC AR6 scenarios for limiting warming to 1.5°C include substantial carbon capture estimates of 2.3 peta-grams annually by 2050. This includes planting over 700 million hectares of forest land (Forster et al. 2018). Armani et al. (2022) stress the urgency of conserving carbon-rich ecosystems by adopting sustainable agriculture and implementing land-based carbon dioxide removal strategies. This can stabilize the climate and assure community livelihoods and regional development. Historically high-emitting countries can provide the requisite financial support, technology transfer, and capacity-building assistance through multilateral financial institutions {18.2.1; 18.2.4}.

20.4.2.4 Economic and Financial System reforms



To meet the basic needs of water, food, energy, and finance, Africa needs robust climate change adaptation and net-zero plans with clear targets supported by enabling policies, regulatory frameworks and good governance mechanisms. Effective governance is essential for reducing emissions, fostering businesses, creating jobs,

Box 20.1: The green hydrogen economy in regional development. The case of Namibia

Green hydrogen (GH2), produced via renewable-powered water electrolysis, is a carbon-neutral energy carrier that can reduce emissions in hard-to-abate sectors like shipping and aviation. While currently costlier than fossil fuels, GH2 and its derivatives, such as green ammonia, methanol, and kerosene, are projected to become cost-competitive within two decades.

Namibia, leveraging its solar, wind, and coastal resources, has attracted over US$9 billion in foreign investment. The country aims to export GH2 products, create jobs, and support decarbonization. Societal impacts on SDGs 7, 8, 9, 13, and 1 to 2050 have been modeled (**Figure 20.3**)

Figure 20.3: Simulated SDG attainment at year 2050 with and without investment

The simulations explore three scenarios. The government requires that GH2 development ensure net gains in electricity, water, and biodiversity protection. GH2 investments drive GDP growth, enabling government spending on education, health, and infrastructure, related to SDGs 1, 7, 8, and 9. SDG 13 shows little progress because GH2 primarily reduces emissions without addressing adaptation. The simulations indicate that GH2 can provide social benefits if coupled with policies for environmental protection, job creation, and access to water and electricity. Global decarbonization commitments and uptake, like Maersk's green methanol vessels and the EU's sustainable aviation fuel mandate, are crucial to drive GH2 demand and prevent stranded assets.

and ensuring prosperity,while adequate financial resources are needed to implement national climate and biodiversity plans to fulfil global commitments (UNEP 2023; UNEP 2024). Africa's investment in green transition is expected to reach US$190 billion annually between 2026 and 2030, significantly lower than the US$1.6 trillion required annually to meet the region's sustainable development needs by 2030 (OECD 2023). Sub-Saharan Africa will need US$835 billion in capital investment by 2040 to meet rising electricity demand (Amir and Khan 2022). Increasing private finance is essential to supplement limited public resources for climate action and green growth. Diversifying into non-traditional exports like carbon credits can unlock funding. With banks holding over 90 per cent of financial assets (ECA 2020) and financing tools lagging behind other regions (Fintech 2022; CPI 2024), sector reforms can provide businesses with cheaper finance, enhance competitiveness, and drive reinvestment, creating a virtuous cycle (Obiwulu et al. 2022). Africa can enhance access to international finance from multilateral financial institutions such as the Green Climate Fund, Global Environment Facility, and Adaptation Fund, by reforming the global climate and nature funding architecture, diversifying financing instruments, and strengthening national capacity and coordination (CPI 2024) {14.3, 14.4;14.4}.

20.4.2.5 Implications of the transformations

20.4.2.5.1 Socioeconomic system

Implementing technology-focused transformation can exacerbate existing insecurities in Africa. Prioritizing advanced technologies may deepen climate and energy inequalities, marginalize Indigenous and local practices in agriculture and fisheries, worsen food insecurity, and drive displacement through land grabbing, exacerbating the marginalization of vulnerable communities (AfDB 2016; IPCC 2021).

Meeting the Paris Agreement target could prevent over 15 per cent of Africa's projected mid-century GDP loss, highlighting its growth potential. With vast human and natural resources, Africa is well-positioned to develop its agriculture, renewable energy, manufacturing, and agricultural sectors (Saba et al. 2023). Although this will require significant infrastructural and human investment, leveraging technology such as precision agriculture in farming, smart grids in energy, and digital manufacturing in industry can amplify these opportunities through robust data systems. In addition, the need for context-relevant climate information and developing robust climate services and forecasts are vital for Africa's ability to adapt to climate change, bridge the gap between scientific data and practical action and build a sustainable future (Vogel et al. 2019; Nkuba et al. 2019). Africa's expanding tech industry and renewable energy potential can drive job creation, economic growth, and climate resilience. Decentralized energy systems can transform rural areas, improving healthcare and green job opportunities, especially for women, while agricultural innovations empower smallholders and youth, and early warning systems enhance adaptation and disaster risk reduction. However, Africa's transformation must be guided by the imperative of aligning with SDGs to ensure the well-being of its population. This alignment, which prioritizes poverty reduction, food security, and inequality, is crucial (Zhang 2024). Tenaciously implementing enhanced nationally determined contributions (NDCs) is a key step in reducing future economic losses.

20.4.2.5.2 Unintended environmental consequences

Climate extremes are introducing significant uncertainty and volatility to Africa's energy and food sectors. This underscores the need for Africa to diversify its energy mix, exploring other renewable energy sources such as green hydrogen, solar and wind while transitioning to more regenerative, inclusive and resilient food systems. Addressing these challenges requires a holistic approach that considers the interconnectedness of these sectors, acknowledging that there may be unintended consequences or unforeseen feedback loops across different horizons.

While technology adoption can drive progress, the increased demand for devices and manufacturing facilities may lead to overconsumption of resources, increased carbon emissions, biodiversity loss, and land degradation (Pindiriri and Kwaramba 2024). Unequal access to technology could widen the digital divide, exacerbating multidimensional vulnerabilities. Additionally, the demand for critical energy transition minerals may cause deforestation, habitat destruction, and soil erosion. Intensive use of agrochemicals in advanced technologies could further degrade soil fertility.

Box 20.2: A carbon footprint integrating all ecosystem elements: application to Indigenous Knowledge systems of pastoral livestock production in the Sahel

In the Sahel, pastoral livestock farming exploits an extreme environment and is often accused of emitting too many greenhouse gases per kilogram of milk or meat produced. Research in Senegal showed that pastoral livestock farming, grounded in Indigenous Knowledge of landscape ecosystems, biodiversity, and ecosystem service dynamics, can achieve a neutral carbon footprint. In other terms, animal emissions are offset by carbon sequestration in soils and vegetation. The study, conducted i n northern Senegal, found that the ecosystem method used takes into account the entire ecological functioning of a territory, focusing on specific processes like animal consumption of fodder on the stalk and used an original method to estimate the indigenous practices of feeding behavior of ruminants and the emission of methane from their digestion, called "enteric methane." The study proposes new standards for daily ingestion, such as 18g/kg for cattle and 34g/kg for small ruminants. The carbon footprint was calculated by assessing all greenhouse gas emissions and carbon sequestered, converting these flows into carbon equivalents.

The new daily intake standards are adjustable (+12%) depending on the territory's resources, livestock practices, and seasons. Despite this, they have consequences for estimating enteric methane emissions: for Sahelian cattle, current official estimates are believed to be twice the actual level. These standards could contribute to revising those used i n the guidelines of the IPCC. The work showed that the territory's carbon footprint is balanced, even if it varies depending on the location and the season. In the area studied, one hectare of pastoral ecosystem emits 0.71 tonnes of carbon equivalent per year and sequesters 0.75 tonnes; in other words, it stores the difference, or 40 ± 6 kilograms of carbon equivalent.

In the Sahel, storage in trees, shrubs, and soils offsets greenhouse gas emissions from animals linked to their diet and the deposit of their droppings. More precisely, the annual carbon footprint varies from one location to another, and this variation is linked to livestock farming practices. Grassy, shrubby, and wooded rangelands, where animals move to graze, are places where sequestration prevails. Conversely, rest areas near camps and the areas around watering points, which receive a lot of droppings, are places that emit the most carbon.

Promoting Indigenous Knowledge Systems of pastoral livestock management covering nearly 1.3 million hectares on the international carbon market is an opportunity for Africa, representing significant potential for carbon sequestration. Green funds and carbon credits could also be mobilized for the benefit of pastoral livestock farming in sub-Saharan countries.

The carbon footprint per hectare offers a valuable additional indicator for assessing the performance of extensive grass-based livestock systems in tropical regions. Hence, by advancing the debate on pastoral livestock farming, this metric aligns closely with the objectives of the Koronivia Joint Work on Agriculture, adopted at the 23rd Conference of the Parties to the UNFCCC (COP 23, 2017).

Source: Adapted from IPBES (2018) and Imarc Group

20.4.3 Behaviour-focused Transformation Pathway

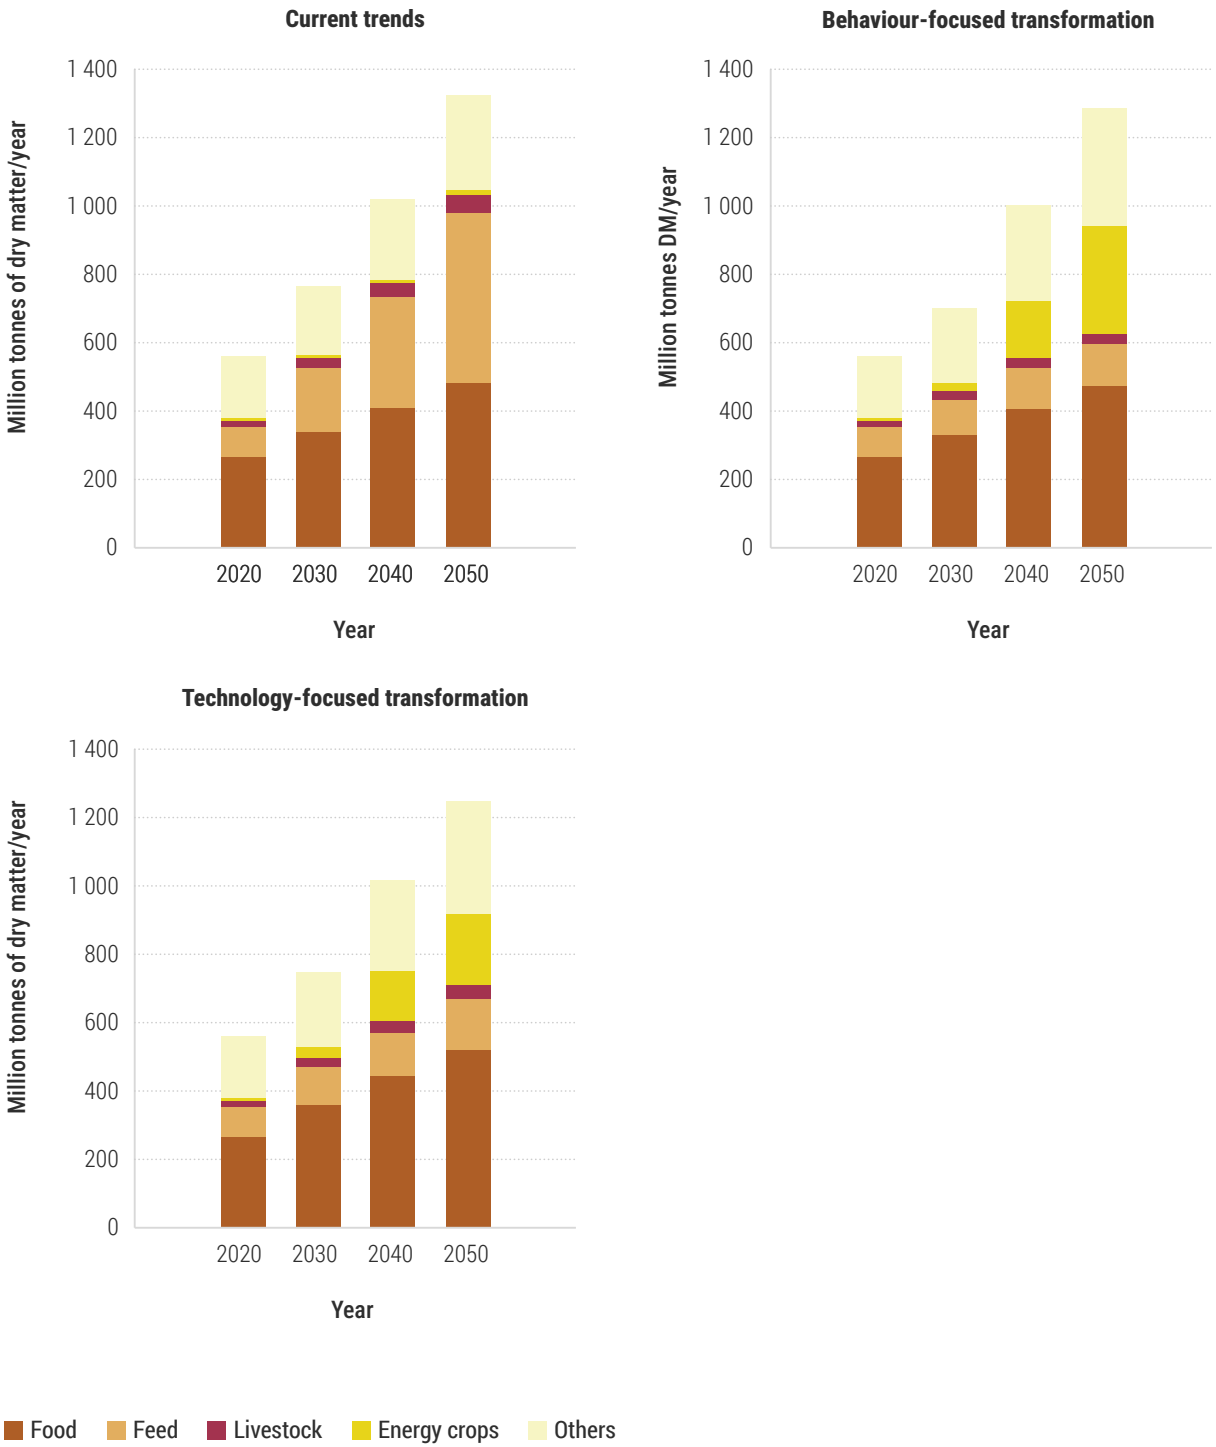
Behaviour-focused transformation can drive local and individual actions by changing behaviours, social norms, and collective efforts through nature-positive activities and renewable energy solutions.

20.4.3.1 Implications of energy system transformation

By addressing both the supply and demand sides of the energy equation with a holistic, integrated, and Africa-led approach, the continent can achieve universal energy access, drive sustainable economic growth, and become

a global leader in the clean energy transition. Countries can promote sustainable consumption and production by using financial incentives and raising awareness about nature's true value (Khanna et al. 2021), encouraging the adoption of renewable energy (Global Wind Energy Council [GWEC] 2019; IEA 2019), reducing waste, and fostering environmentally responsible behaviours. These would concomitantly conserve the region's forests and biodiversity due to reduced solid biomass burning. The renewables would complement the installed hydropower capacity (Cáceres 2022) whose scalability is impeded by its capital-intensive nature (McMillan and Zeufack 2022)and frequent outage (Ateba and Prinsloo 2018) as well as increasing frequency of floods and droughts the solution for which is building of climate-resilient hydropower infrastructure (IEA 2020).

As Africa ascends the energy ladder, the focus could shift to educating households to purchase energy-efficient appliances and to ingrain electricity-saving practices such as keeping building doors and windows closed when using heating, ventilation, and air-conditioning (HVAC) systems (Mutumbi et al. 2022), and embracing green architecture and sustainable building codes and building with sustainable construction materials. Access to affordable capital would enable industrial and mining sectors to invest in more energy-efficient machinery and processes (Apeaning and Thollander 2013; Du Plessis 2015). Africa's transport sector can be nudged to adopt more energy-efficient vehicles through economic instruments (such as punitive taxation) that ensure the internalization of externalities, alongside investments in mass rapid transit systems and provisions for non-motorized travel through smart spatial planning and design (Agyekum et al. 2023; Lefèvre & Mainbuy 2009) (Lefèvre and Mainbuy 2009; Agyekum et al. 2023) {16.2.1-16.4.2}.



20.4.3.2 Implications of food system transformation

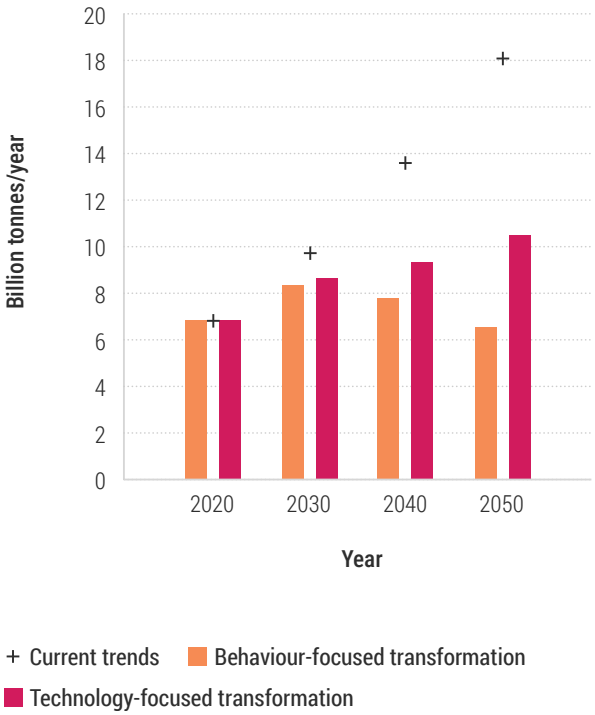
Africa's food systems can be transformed to meet four policy priorities: accessibility, affordability, availability and inclusivity (Global Panel on Agriculture and Food Systems for Nutrition [GPAFSN] 2020). Governance reforms that dismantle conceptual and institutional silos around agriculture, biodiversity, forests and land, and entrench integrated practices such as conservation-based intensification and agroecology can markedly increase and stabilize yields, assure energy, food and nutritional security, reduce poverty (Islam et al. 2019; Mrabet and Moussadek 2022), and enhance the provision of ecosystem services (DeClerck et al. 2023). At the international level, there is need for coordination among multilateral environmental agreements to ensure that cross-cutting issues are addressed collectively. At national level, leveraging Indigenous Knowledge for cultivar and culinary diversity by incorporating commercially producing protein-rich edible insects in select communities and practising specialized farming systems can provide good health benefits with strong safety and quality regulations (Kelemu etal. 2015; Van Huis 2015; Matandirotya et al. 2022). Underutilized crops such as finger and pearl millet, sorghum, tubers, and legumes (Popoola et al. 2023) can be promoted by encouraging the consumption of the leaves, flowers, fruits, stalks, bark, and roots (UNEP 2023). Nutritious and well-adapted African super foods, promoted through advertisements and product placement (WFA 2021; Herrero et al. 2023), can enhance flavour and reduce waste. This can bolster impoverished communities' food security and food sovereignty (Van Huis 2015; Smith et al. 2021). Postharvest loss and waste can be addressed across the value chain through adoption of preservation technologies and building consumer awareness (Cattaneo et al. 2021).

As depicted in **Figure 20.4**, the period 2025-2050 witnesses a marked increase in energy crops in behaviour-focused transformation with a sharp inflexion in 2037, mainly at the expense of feed crops, emphasizing the role of behavioural spurs in driving the shift from animal to plant-based, lower carbon-emission diets. The anticipated rise in demand for energy crops under the behaviour-focused transformation is considerably higher than that projected under the technology-focused transformation, pointing to the role of raising consumers' environmental consciousness in driving demand for cleaner energies such as biofuels. Nevertheless, a degree of technological innovation anticipated under the technology-focused transformation will be needed to boost demand for sustainable energy crops, as they optimize energy extraction (Toromade et al. 2024; Ezeh & Agu 2025; Akinbobola et al. 2025).

Promoting a combination of transhumant and stable livestock farming is crucial for improving the carbon efficiency of food production. While ranches in the low-rainfall areas (less than 500 mm/year)

Figure 20.4: Shift towards a plant-based diet from 2020 to 2050

of Australia and the United States produce 0.3 to 0.5 kg of animal protein per hectare per year, the transhumant Fulani herds in the comparable Sahel of Mali produce markedly more meat of 0.6 to 3.2 kg per hectare per year. Similar productivity trends are observed among transhumant herders in East Africa, highlighting the benefits of traditional pastoralism over ranching {17.2.1-17.2.4}.



20.4.3.3 Implications of materials/ waste system transformation

Sustainable material production and consumption transformations are essential to conserve Africa's finite resources, whose demand under the Current Trends Scenario is projected to rise by 150 per cent to 17,800 MT/yr by 2050. Although simultaneously

implementing Technology and Behaviour-focused Transformation Pathways produces the best results, behaviour-focused transformation pathway promotes a noticeable behavioural shift from linearity to circularity, conserving resources and minimizing adverse environmental impacts. Public awareness drives geared at reducing conspicuous consumption can complement technological advancements in material recycling, as shown in **Figure 20.5.**

Africa's material and waste management systems can only be transformed if resource-efficient technological innovations are complemented with behavioural shifts towards sustainable consumption and waste generation. Key shifts include integrating resource-efficient manufacturing technologies and processes (UNEP 2019), circularity models that prioritize sustainable product design, extended product lifespans, and products that are reusable, repairable, and recyclable (UNEP 2022). Embedding these practices into corporate culture and aligning them with individual, departmental and organizational performance metrics are essential for long-term success. In addition, widespread adoption of B2B and B2C e-commerce platforms can help reduce the carbon footprint associated with traditional intermediation (Nwokolo et al. 2023). Digital platforms, such as block-chain-based apps, offer further potential as enable

Figure 20.5: Total materials demand as a function of transformation pathways

material traceability, improve demand management, and match suppliers with buyers in real-time (IEA 2020; UNEP 2023), thereby streamlining the value chain through disintermediation. Moreover, investing in and scaling waste-to-energy technologies, waste-to-soil enhancers, and digital waste management infrastructure can mitigate the environmental impact of Africa's rapid urbanization, which is expected to continue beyond 2050 (World Economic Forum [WEF] 2022; UNEP 2023){15.2.3}.

20.4.3.4 Implications of finance and economic system transformation

Overhauling Africa's finance system to make it more climate and biodiversity inclusive will necessitate both supply and demand side interventions. The sustainable funding per capita from international public sources such as multilateral financial institutions, bilateral cooperation and private global private sources in the form of lending and blended finance as well as domestic public and private sources (Ludwig 2021; Atteridge et al. 2022; Brears 2022) needs to be substantially increased and made more affordable. This will bridge the annual financing gap for nature-based solutions estimated to total US$230 billion by 2025 and US$674 billion by 2050 while that for climate resilience and adaptation will exceed US$127.2 billion per year by 2030 (AfDB 2023). Through compliance and voluntary carbon markets, Africa can leverage its untapped CO_2 potential estimated at 2,400 metric tons ($MtCO_2e$) per annum, 400 $MtCO_2e$ of which can be technically harnessed by 2030, unlocking US$7 billion annually (Africa Carbon Markets Initiative [ACMI] 2022). Development and commercial banks can educate staff to green their loan portfolio by attracting sustainable projects particularly to meet national priorities and to capitalize on the anticipated demographic dividend. Integration of climate risk management considerations into financial operations and lending practices should ensure transparency and accountability in their monitoring and evaluation systems, and incorporate environmental, social, and governance factors into annual reporting (UNEP 2023). Implementing national, economic bloc-wide and region-wide projects under the auspices of the AfCFTA can create synergies and level trading playing field. Beyond Extended Producer Responsibility schemes, Africa could develop and adopt Ultimate Producer Responsibility, which establishes a fair funds transfer mechanism for imports of used goods. Ultimate

Producer Responsibility ensures that producers bear fair costs when their responsibilities for end-of-life management of goods shift across national borders and with government and private sector support, provides opportunities to transition to more circularity and sustainability (Peng et.al. 2023). In addition to tackling the continent's waste management issues, Ultimate Producer Responsibility would radically alter global supply chains, encourage the creation of genuinely sustainable products everywhere, and guarantee a fairer and just shift to a circular economy on a global scale. If Africa can invest the money it currently spends in fossil fuel subsidies in circular-economy-related technology adoption and infrastructure development, there can be positive changes in the materials, agrifood, energy and environmental systems (UNEP 2024). Although initial economic costs will be higher, the health, environment and biodiversity benefits will outweigh costs in the long-run Accordingly, Africa's position as a global leader in sustainable development would be cemented by this {14.3-14.6}.

20.4.3.5 Implications of Environmental system transformation

Under the behaviour-focused pathway implementation, the accelerated destruction of Africa's biodiversity and mean species abundance projected by the Current Trends Scenario can be reversed for all species, although this may not lead to distinct improvement possible under the technology-focused pathway. Moreover, emissions of black carbon, organic carbon, and sulfur dioxide can exhibit a general downward trend following implementation of stringent regulations while those of ammonia emissions grow nominally owing to its widespread reuse. However, emissions of volatile organic compounds peak in 2025 at 43Mt, bottom out in 2038 at 31Mt before steadily rising to 38Mt by mid-century, driven by both rising energy consumption and legacy inefficiencies. Water withdrawals for electricity use can decrease rapidly before 2040 if there is a switch from fossil-fueled thermal power plants to renewables. The potential of irrigation water, particularly in sub-Saharan Africa, would nevertheless largely remain untapped, impeded by limited access to technology, technical know-how and finance (Bjornlund et al. 2020; Bedasa 2023; Galbert and Olinga 2023), policy and institutional constraints (Mohammedshum 2023) and cultural and social norms, including on traditional gender roles (Fredriksson and Gupta 2023){18.2.1; 18.2.4}.

20.4.3.6 Implications of the transformation under Behaviour-focused Transformation Pathways

20.4.3.6.1 Socioeconomic system impacts

Africa's growing population could demand more sustainable food production, which could raise food prices beyond the reach of the groups living below the poverty line, exacerbating rather than alleviating hunger and malnutrition (Mehra et al. 2024). The anticipated shift towards renewable energies and carbon-resilient development will create considerable job opportunities for the region's growing population. Further, the adoption of renewable energies has the potential to foster universal access to clean energy, contribute to health and well-being, mitigate inequalities, empower women, promote decent work, and stimulate economic growth (Balgehshiri and Zohuri 2023).

To address the spike in climate change impacts due to both extreme and slow-onset events especially on the health systems, Africa needs to invest in the physical infrastructure and a skilled workforce development making them resilient to climate-related risks, shocks and stressors and other emergencies (AfDB 2023).

Behavioural shifts towards responsible environmental stewardship can mitigate conflicts over land and its varying tenure systems and resources, subsequently reducing the prevalence of inter-community and gender-based violence and discrimination. Moreover, training and providing financial resources can empower women, youth and marginalized groups to participate in natural resources management, the economy and society and encourage them to adopt sustainable consumption practices. Therefore, the benefits of behavioural transformations transcend the environmental space, promoting overarching sustainability, equality, education, health care, financial inclusion and overall societal well-being in Africa.

20.4.3.6.2 Unintended consequences for the environmental system

Policies encouraging eco-friendly behaviours – such as incentives for afforestation, renewable energy adoption, or sustainable food system – need to support ecosystem restoration considering local environmental dynamics and social complexities. Large-scale tree-planting initiatives, for example,

should not lead to monoculture plantations that deplete soil nutrients, biodiversity and water resources. Similarly, promoting biofuels or alternative materials should be based sustainable land management to prevent deforestation, habitat loss, and increased carbon emissions. Overreliance on behavioural nudges, such as consumer-driven recycling initiatives, may also shift responsibility away from systemic solutions like improved waste management infrastructure or stronger environmental regulations. Furthermore, policies that impose new environmental costs, such as taxing single-use plastic without providing affordable alternatives, can push communities towards unintended substitutes that may be more harmful. Behavioural interventions therefore need to be holistic and context specific.

20.4.4 What does that mean for the regional priorities?

20.4.4.1 Implication of combined technology-focused and behaviour-focused transformations on regional priorities

The technology and behaviour-focused transformations are interdependent and should complement each other to address the environmental priorities detailed in Chapter 8 and highlighted at the beginning of this section. While technological innovations provide physical and digital tools to help solve hitherto intractable problems, and optimize efficiency and productivity, unlocking their full potential necessitates corresponding shifts in behaviour (**Table 20.2**).

Table 20.2: Drivers and actions for each transformation pathway

Systems	Technology-focused Transformation		Behaviour-focused Transformation	
	Drivers	Actions	Drivers	Actions
Economic and finance {14.3-14.6}	Reforming economic and financial systems for sustainable and green growth, poverty reduction, and resilience to global shocks.	• Macroeconomic stability • Development and reform of finance sector • Increasing private and international finance • Diversifying financing instruments • Enhancing creditworthiness and risk mitigation	Ensuring financial flows actively support environmental sustainability and human development.	• Develop and adopt the Ultimate Producer Responsibility • Developing green financial products and instruments • Strengthening financial institutions' capacity • Fostering compliance and voluntary carbon markets • Mixing or blending various financial mechanisms
Material and waste {15.2.1}	Leapfrogging to circularity and integrating zero-waste policies into its development.	• Sustainable construction • Resource-efficient manufacturing • Smart urban planning • Material efficiency technologies • Capacity-building and awareness • Responsible management for abundant resources	The indispensability of behavioural shifts to conserve Africa's finite resources while foster inclusive economic growth.	• Integrate sustainable consumption and waste generation practices • Resource-Efficient Production and manufacturing • Investing in and scaling waste-to-energy technologies, waste-to-soil enhancers, and digital waste management infrastructure

Systems	Technology-focused Transformation		Behaviour-focused Transformation	
	Drivers	Actions	Drivers	Actions
Energy {16.2-16.4}	Accelerate rural development and share of renewables dominant energy source by 2050 and aligning with global decarbonization goals.	• Increasing access to electricity • Incentivizing energy efficiency programmes • Strong commitment to renewable energy including green hydrogen	Sustainable Energy production and consumption.	• Leveraging Africa's abundant renewables • Bundling efficiency and behavioural change
Food {17.2.1-17.2.5}	Integration of conservation and restoration of nature with ecologically intensive food systems.	• Technology integration for sustainable and resilient food systems (agroforestry, conservation agriculture, forest landscape restoration etc.) • Sustainable water management and wetland regeneration and restoration • Nature-positive investments for protecting invaluable natural heritage • Capacity-building and awareness	Achieving triple-win" approach: food security, environment and social harmony.	• Diversified Farming Systems including combining transhumant and stable livestock farming • Dietary change through leveraging indigenous cultivar and breads and culinary diversity • Conservation-based intensification and agroecology • Investing in Human Capital
Environment {18.2.1; 18.2.4}	A holistic approach to environmental sustainability: transform environmental challenges into opportunities.	• Interconnectedness among drivers and Nexus thinking • Technology-focused, resilient, equitable, and sustainable development • Ecosystem-based management and Nature-based Solutions • Advancing science, fostering research, and strengthening institutional capacity	Going beyond incremental improvements to a truly transformative path of ecosystems with behavioural shifts and development.	• Promoting people-centric and inclusive development. • Prioritize policies that actively encourage eco-friendly behaviours through a mix of incentives. • Guaranteeing a strong pipeline of investable green projects.

In reversing ecosystem degradation and vulnerability, tempering depletion pressures and enhancing disaster risk reduction, the technological pathway could offer solutions which optimize resource utilization and entrench sustainable land management practices such as precision agriculture; safe, affordable, inclusive and low-carbon food system and shorter agrifood value chains. The corresponding behavioural transformation would promote shifts towards sustainable consumption patterns and land-use practices, further supporting ecosystem restoration and conservation. To bolster climate change adaptation, technology-focused transformation offers renewable energies and climate-smart agriculture. These can be complemented by behavioural changes that promote energy efficiency and conservation mind-sets.

Overall, while the technology-focused transformation provides the innovations or the "hardware" to urgently address the three regional priorities, the behaviour-focused transformation pathway offers the critical "software" part of the equation, reinforcing sustainable production and consumption patterns which in turn create demand for successively more sustainable innovations and practices, fostering synergies and creating a virtuous cycle and ultimately driving Africa's sustainable development.

20.4.4.2 Reflections: Synergies

20.4.4.2.1 Synergy by strengthening Interlinkages

The five systems are interdependent and achievements in one have co-benefits for other systems, the environment and human well-being. Equally, the Technology and Behaviour-focused Transformation Pathways can complement each other in several ways. First, the development and implementation of new technologies can influence consumers' behaviours including purchase decisions. For example, the availability of affordable, efficient renewable energies can encourage consumers to reduce their reliance on fossil fuels. Second, the behaviour-focused transformation pathway can drive demand for new technologies. As people become more aware of the scale of the global environmental crises and the concomitant need for environmentally sustainable practices, they may demand incrementally innovative technologies or quantum leaps. This demand can lead to the development and adoption of new technologies, further promoting sustainable practices. Third, technological innovations may lead to behavioural shifts, which may in turn lead consumers to demand even more environmentally sustainable products, chaining off a perpetually reinforcing virtuous cycle.

20.4.4.2.1 Balancing synergies and trade-offs

In the African context, the synergies of adopting both the complementary Technology-focused and Behaviour-focused pathways can help reinforce lasting, holistic and sustainable transformation for the five systems – energy, food, materials and waste, economic and financial and environmental – and yield co-benefits for inclusive human well-being for the region's population.

The trade-offs between the two pathways require careful balancing, so that environmental, social, and economic objectives are aligned rather than placed in conflict. Organizations should weigh initial capital investments against long-term sustainability and resource efficiency gains. Managing the complexity of technology adoption while integrating behavioural changes across diverse developmental, environmental, cultural and resilience-related national contexts calls for transformative strategies. Another critical consideration is navigating technological dependency while empowering local, Indigenous and marginalized communities to build self-reliant, inclusive and resilient practices.

20.4.5 Policy implications

The policy implications of the above analysis revolve around integrating natural resources management, good governance, overhauling economic and finance systems and embedding circularity principles across entire value chains. Regional and national policymakers could leverage some of the flagship projects of the African Union's Agenda 2063 to ensure unified regulatory frameworks that address externalities and foster sustainable environmental practices across the continent. Possibilities include development of the Grand Inga Hydropower Project, the creation of a regional trading strategy, the establishment of continental financial institutions, and the implementation of the AfCFTA. Integrating environmental management would entail multi-sector and multi-stakeholder governance among entities sharing similar mandates such as those which are responsible for the environment, energy, forests, agriculture, economic development and finance. An important first step in this direction could be establishing national interministerial councils for addressing climate, agriculture and forest and other land uses.

Effective funding governance is key to addressing environmental crises by ensuring resources are allocated efficiently and equitably. Clear guidelines can prioritize climate-resilient projects that benefit marginalized communities while supporting sustainable development. Strong governance also enables monitoring and evaluation, ensuring accountability and transparency, which builds public trust and participation. Transforming financial systems by greening loan portfolios of public financial institutions and incentivizing private sector can redirect resources towards green initiatives such as circular economy,

Credit: ©UNEP

renewable energy, climate-resilient agriculture and infrastructure blue/green economy etc.

International coordination among multilateral environmental agreements is essential for identifying synergies, preventing policy conflicts, and promoting a holistic approach to environmental management. While multilateral environmental agreements often address specific issues like climate change or biodiversity, greater cooperation can foster integrated solutions that consider land-sea connections, biodiversity-climate links, and the balance of conservation, restoration, and sustainable use of ecosystems.

The African Union Agenda 2063's flagship projects, including the AfCFTA, offer significant opportunities to address regional priorities by establishing a unified regulatory framework across member countries. This framework could enforce standards for emissions control, energy efficiency, and waste management, promoting sustainable environmental practices. AfCFTA can also facilitate the trade in products that are made with sustainably sourced raw materials and environmentally sound manufacturing methods, incentivize conservation efforts, and support biodiversity protection. Furthermore, it can accelerate the continent's clean energy transition by promoting cross-border exchange of renewable energy, production thus, reducing reliance on fossil fuels. Additionally, AfCFTA could introduce mechanisms for carbon trading and emissions reduction commitments, encouraging member countries to lower their carbon footprints and enhance climate resilience (Lokotola et al. 2023).

20.4.6 Conclusion

African countries can make significant progress towards achieving sustainable development and net-zero goals by 2050, despite challenges of poverty, capacity gaps, and infrastructure limitations (Royo et al. 2022). Through ecosystem restoration, promoting sustainable resource use, and building resilience to climate change and extreme weather events, they can unlock new growth opportunities. Progress will vary across subregions, with more advanced economies benefiting from greater technological and financial resources. With enhanced investment, international cooperation, technology transfer, innovation, sensitization, education and transformative policy reforms, Africa can drive its energy transition, strengthen climate adaptation, and advance low-carbon growth in line with its development goals.

20.5 Asia and the Pacific Region

20.5.1 Introduction

The Asia and the Pacific (AP) region is bio-culturally and geographically diverse in its state of environment and development, facing numerous challenges and opportunities (UN 2024). The key priorities of the region are climate change adaptation and resilience building against extreme events, land-use change and land degradation, and increasing waste and pollution (Chapter 8). Increasingly severe climate-induced disasters destroy lives and livelihoods in many Asian countries (IPCC 2023). Significant gaps persist in reducing GHG emissions to limit warming, as presented by the Paris Agreement (IPCC 2023).

While many countries in the region have undertaken effective measures for ecosystem restoration, biodiversity conservation and climate change adaptation (United Nations Economic and Social Commission for Asia and the Pacific [UNESCAP] 2023), further efforts are needed to ensure a sustained flow of ecosystem goods and services to achieve the SDGs by 2030. Overall, conserving biodiversity and sustainably managing natural capital can be a basis for enabling the region's economic growth and social welfare.

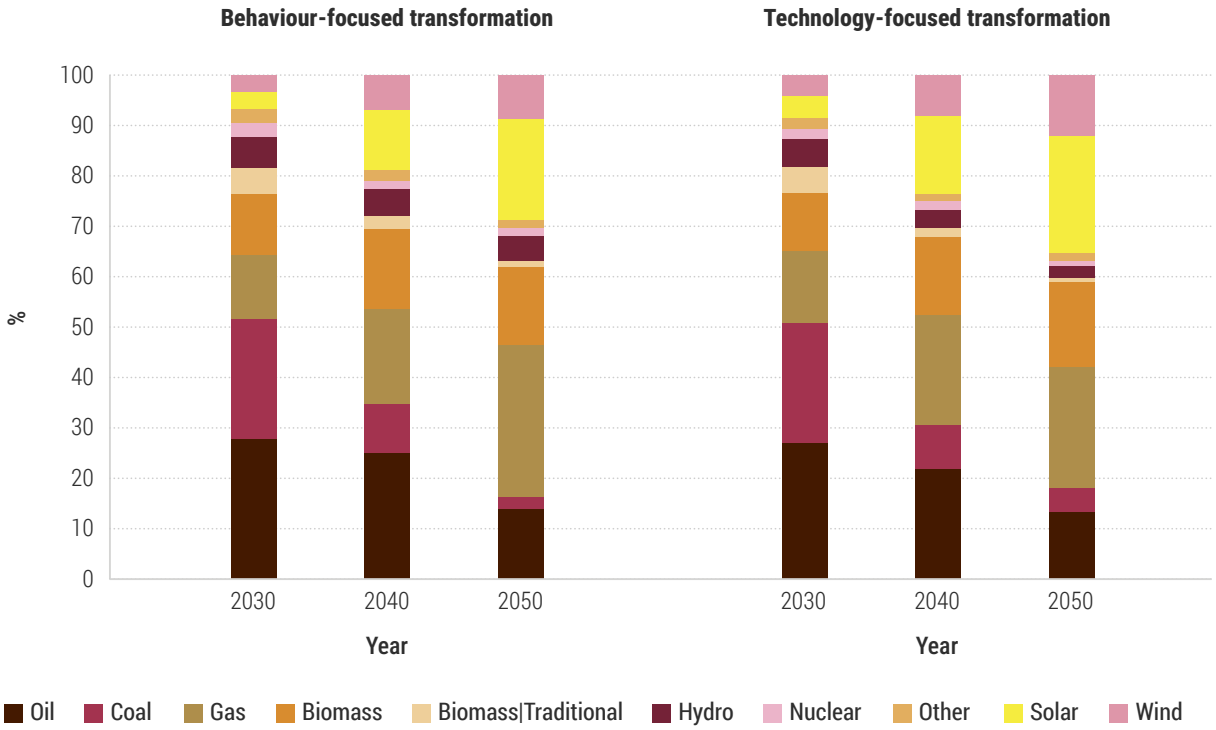
Asia and the Pacific countries have achieved only 17 per cent progress in the 17 SDGs – slightly above the global level. However, at the current rate, the AP region will fail to achieve 90 per cent of the 118 SDG targets by 2030 (UNESCAP 2024). Although 39 Asia and the Pacific countries have pledged to reach carbon neutrality and net-zero targets by the 2050-2070 period, few countries have developed enabling frameworks to implement NDCs to meet their net-zero pledges. The region can achieve global goals and targets only if it raises ambition in their NDCs to reduce GHG emissions and meet Paris Agreement goals (UN 2022c). The region's countries can accelerate progress through building resilience and leveraging synergies between climate and development (UN 2024).

AP countries need major transformation in energy, food, water, and material systems while simultaneously transforming their and finance systems to avoid continuing with Current Trends practices that are detrimental to all.

Chapter 11 presented transformative pathways that, if adopted either individually or in combination, can fast-track integrated and holistic solutions for these systems through simultaneous transformation of economic and finance and environmental systems to address global environmental crises. The pathways for system-wide transformation are described below.

20.5.2 Technology-focused Transformation Pathway

This pathway calls for transitioning away from fossil fuels and towards green fuels and renewable energy sources. However, technology-focused pathways depend upon reforming regulatory frameworks, finance, respecting Indigenous Peoples' aspirations, infrastructure development and enhancing energy efficiency. Tailored transformation-based solutions for the region are described below.



20.5.2.1 Transition to green energy

The AP region is projected to have the highest demand and supply of clean energy power by 2050 (UNDP 2022a). Renewable energy resources and low-carbon technologies are expected to penetrate multiple sectors in different proportions across the region. In the primary energy mix (6), the renewable energy penetration is projected to increase about 11 times, between 2020-2050, with 38 per cent of non-biomass renewables share by 2050. In the case of fossils, new plants could be developed with carbon capture and storage. (Chapter 11)

The primary energy is expected to decline in the short term (2020-2040), due to transition towards best-available-technologies resulting in significant efficiency improvement while it increases post 2040, due to growing in energy demand (**Figure 20.6**). (11.3.1)

Renewable energy and penetration of green fuels such as green hydrogen and biofuels into the energy system requires enhancing and strengthening of grid infrastructure (Pandey and Asif 2022; Asif et al. 2024), securing additional land, innovative financing (IRENA 2023; Skalamera 2024), phasing out fossil fuels subsidies, holistic policies and regulations (Hamelin and Bhatti 2023; IRENA 2023). It also calls for private sector involvement (Azhgaliyeva et al. 2019; IRENA 2023; Asif et al. 2024), fast-tracked planning, manpower training (IEA 2023),

Figure 20.6: Percentage share of primary energy mix in Asia and the Pacific region

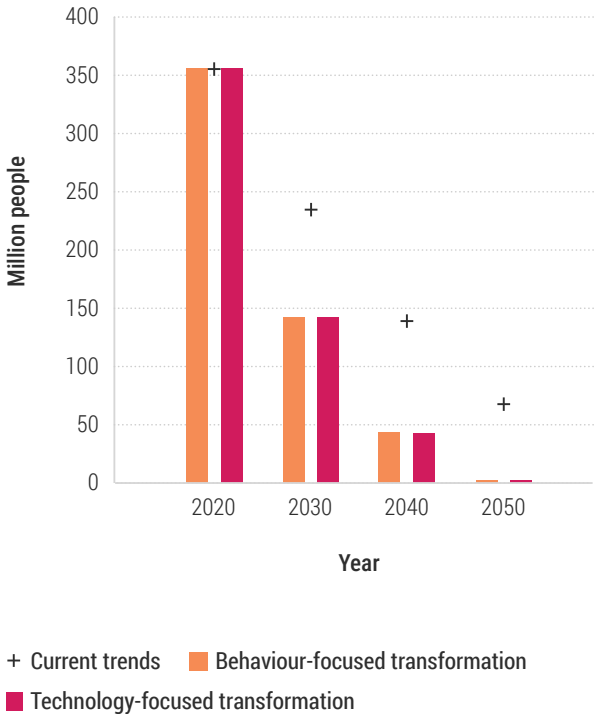
policy and technology adoption from best practices, data repositories, and regional grid development. Additionally, electricity storage technologies, such as batteries and pump storage are crucial for supporting renewable penetration by maintaining grid stability (Chapter 16). Among subregions, Central and South Asia has great potential for solar and hydropower, which could be harnessed through individual and hybrid power plants (Azimov and Avezova 2022; Zakeri et al. 2022). The Pacific islands have significant solar potential (Malik 2021; Taylor and Taylor 2022; Prasad and Prasad 2023) and could also explore marine renewable energy (Malik 2021; Kazimierczuk et al. 2023) to utilize their geographical advantage, provided commensurate technological and economic challenges are addressed.

West Asia has potential to invest in hydrogen, solar and offshore wind energy solutions along with climate capture and storage (Bianco 2021; United Nations Economic and Social Commission for West Asia [UNESCWA] 2022; UNEP 2022b).

Asia may see marginal improvements in the use of non-solid cooking fuel by 2030 (IEA 2022b). Adoption of cleaner cooking fuels could be driven by affordability, efficient service, and e-payment options. The final energy consumption as compared to REF-pathway is projected to reduce by 34 per cent in 2050 (Chapter 11). Technological advancements and increased use of electricity-based technologies such as electric vehicles, electric cooking, increased electrification of industrial processes are expected to improve energy system (Pandey and Asif 2022; IRENA 2023; Asif et al. 2024), however the overall energy demand would continue to rise due to increase in population and economic growth {16.2-16.4}.

20.5.2.2 Sustainable agriculture and food system

Food system transformation is critical to the AP region due to increased food demand, production expansion, and increased pressure on arable land, driven by rapid urbanization, climate change impacts, population growth, and income rise. Additionally, environmental challenges such as increased climate extremes and land degradation further strain agricultural productivity by reducing arable land quality. The transformations are possible by adopting both technology-based and behaviour change pathways (Asia Development Bank [ADB] 2020).



Technological advances show promising results in efficient land use, resilient food systems and low fossil-fuel-based food production throughout the supply chain (UNDP 2022). While technological applications hold great potential, it's important to

note that the region cannot achieve the SDG2 targets through the technology-focused pathway alone (**Figure 20.7**). Due to competition for arable land, projected climate-oriented technological solutions such as biofuel may lead to 225 million people at risk of hunger in 2030 and 142 million people in 2050. This is because while technology can increase food production, distribution and resilience, it cannot address socioeconomic, political and environmental causes of crises (APSDG Partnership 2024). However, combining with the behaviour-focused strategies, technology-based solutions can meet higher agricultural demand, while ensuring inclusive access to a healthy diet and addressing the undernourishment issue {17.2.1; 17.2.3; 17.2.4} (Figure **20.6**; **20.7**; **20.8**).

20.5.2.3 Conservation and restoration of nature

Robust environmental management is crucial to overcome industrial-driven resource exploitation that is environmentally harmful (Asian Development Bank [ASEAN] 2023). Prioritizing technological innovation

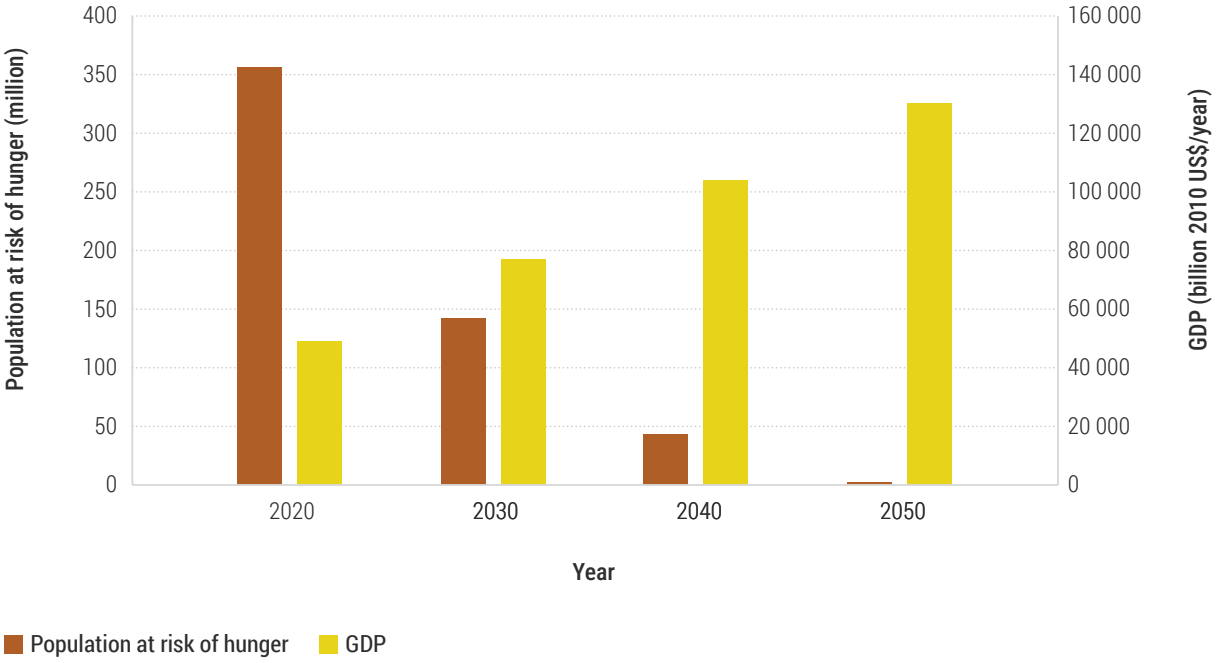


Figure 20.7: Population at risk of hunger

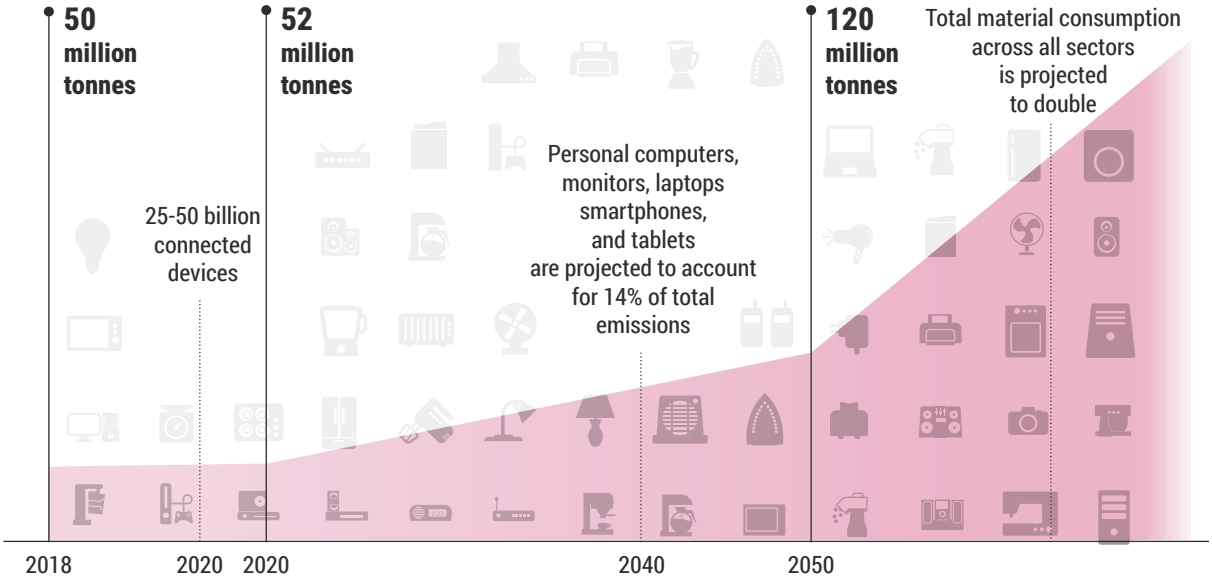
The Living Indus initiative aims to restore 40 per cent of the Indus basin within Pakistan by 2030. Credit: ©UNEP

Figure 20.8: Population at risk of hunger and projected GDP in Asia and the Pacific under the technology-focused transformation pathway

and energy efficiency emerges as key strategies tightly connected to emission reduction, playing vital roles in ecological management. Gradual reduction of chemical fertilizers and pesticides use in the region is possible through conservation-based system intensification, including in livestock and aquaculture subsectors improving water and air quality and contributing to sustainable land management. (Nkonya et al. 2016; Gathala. et al. 2020). Sustainable transformation of the farming system applying the principles of agrobiodiversity conservation and climate-resilient agriculture, combined with green incentive mechanisms, can promote ecological and environmentally friendly food system transformation while eliminating harmful subsidies (CIMMYT 2019; WB 2024).



Small-scale and subsistence farming will remain an important food and income source, and a social safety net in the absence of alternative livelihood security (Giller et al. 2021). Tackling barriers such as limited access to land, education, and credit – especially for women smallholders, is critical to enabling technological solutions such as mechanizing smallholder farms. Favourable policies to promote healthy diets and Indigenous and local food systems can transform the region's food system.

20.5.2.4 Circular Economy and pollution control and prevention

The Asia and the Pacific region's top position in global waste generation, including e-waste, is expected to continue through 2050 (Herat 2021) (**Figure 20.9**). Circular economy solutions can promote sustainable waste management. In West Asia alone, circularity solutions have the potential to result in a 14 per cent reduction in e-waste generation (UNEP 2023).

Asia and the Pacific countries can adopt circular economic solutions comprising of both technology-based and behaviour change-based interventions to improve waste collection, segregation, and material recovery (Francis 2020) {15.2}. Decisions made at each stage of production and consumption – for food waste, packaging, building materials, e-waste, and plastic waste – can focus on reducing, reusing and recycling materials to minimize greenhouse gas emissions, resource consumption, and environmental consequences (Andeobu et al. 2021). The key requirement is enforceable regulatory frameworks and citizens' participation. There is a need for packaging leadership with innovation, easier recycling, creative solutions, and better garbage collection and landfill management policy. Under transformative actions,

Figure 20.9: Future of E-waste

Source: Herat (2021)

countries set ambitious goals in waste reduction, circularity and landfill management. Enabling legal and policy frameworks, can help eliminate single use plastic bags and avoidable plastic packaging. The progress under transformation pathways will be slow initially but should increase by 2030 through a reduction in materials demand. Behaviour-focused transformation pathways reduce demand for industrial round wood most significantly (**Table 20.3**).

Material demand will remain dominant in the Asia and the Pacific region for almost all materials except industrial sand and gravel. The region will be a net importer of materials, especially aluminium, copper, iron ore, and other metals and concentrations. (Chapter 11).

Countries can improve material recycling rates by using technology-focused transformations, aiming to reach 100 per cent recycling as found in the iron ore material category. Behaviour-focused transformations can increase recycling rates slightly compared to the current trends pathway while technology-focused pathways increase the recycling rate more significantly across all eight materials {15.2} (**Table 20.4**).

20.5.2.5 Economic and financial system reforms

Global and regional financial institutions need to undergo major reforms, especially by mainstreaming climate-resilient and nature-positive financing strategies that transform them into environmentally friendly institutions and green-taxonomy-based financial institutions (Song et al. 2023). Environmentally friendly institutions can fund projects and companies that are positively impacting environment and contributing to sustainability. The Asian Development Bank and the Asian Infrastructure Investment Bank can be reformed further to invest in climate inclusive and green initiatives. These financial institutions can scale-up concessional loans, equity investments, guarantees, capacity-building and investment advisory services to support green projects, especially in low-income countries across the region (Asian Infrastructure Investment Bank [AIIB] 2023). The use of public-private partnerships can attract private capital by reducing risks to their investment through public finance. Funds for responding to climate change or other crises-related loss and damage can be provided to vulnerable developing countries in addressing the adverse effects.

To meet carbon neutrality targets by 2050-2070, countries can implement innovative decarbonizing mechanisms including emissions trading systems, voluntary carbon markets, and green bonds to reduce carbon and methane emissions. Enhanced NDCs commitments can be achieved through increased investments in nature-based solutions to protect natural capital including sustainable management

Table 20.3: Annual production, demand, and extraction for different materials

Variable	Scenario	Unit	2020	2030	2024	2050
Forestry Production - Industrial Roundwood	Behaviour-Focused	Mm^3/yr	433	527	459	366
	Current Trends	Mm^3/yr	433	591	678	735
	Technology- Focused	Mm^3/yr	433	493	440	399
Material Demand - Iron Ore	Behaviour-focused	Mt/yr	2660	3090	2730	2500
	Current Trends	Mt/yr	2660	3620	4220	4730
	Technology- Focused	Mt/yr	2660	2830	2570	2600
Material Extraction - Iron Ore	Behaviour-focused	Mt/yr	1190	1380	1210	1160
	Current Trend	Mt/yr	1190	1660	1980	2270
	Technology- Focused	Mt/yr	1190	1290	1160	1190
Material Demand – Total	Behaviour-Focused	Mt/yr	61200	72100	57800	46100
	Current Trends	Mt/yr	61200	72100	96100	98800
	Technology- Focused	Mt/yr	61200	70100	62700	62000

of terrestrial, freshwater and marine ecosystems that can generate mitigation co-benefits as well as improve, protect and sustain livelihoods. However, the availability of external financing and technical support for vulnerable developing countries is required (UN 2022a) {14.3-14.6}.

Residual GHG emissions from energy and industry sectors remaining by 2050 (Chapter 12), could be offset by carbon capture and storage and sustainable land-use and management methods. This transition offers co-benefits such as safeguarding ecosystems, reducing air pollution and enhancing urban sustainability through adaptation and climate-resilient building measures (**Box 20.3**).

Given the environmental challenges faced by the AP region, adopting green investment and innovations become crucial (Adebayo et al. 2021). Similarly, use of technologies such as drones, geospatial information systems, closed-circuit television cameras, smartphone applications, have proven to enhance forest fire detection and wildlife management.

Strengthening regional cooperation is vital to meet both climate and biodiversity goals and targets through knowledge-sharing, technology transfer, and partnership programs (United Nations Educational, Scientific and Cultural Organization [UNESCO] 2023). Regional cooperation can lead to sustainable conservation and use of both terrestrial and marine biodiversity beyond national jurisdictions by strengthening synergies between climate change and ecosystems at landscape and seascape levels. {18.2.1; 18.2.3}

20.5.2.6 Implications of the transformation

20.5.2.6.1 Implication on socioeconomic systems

The transition to a clean energy system is estimated to require an investment of US$14.7 trillion by 2030 in the region, with ASEAN countries alone needing US$2.7 to 2.9 trillion by 2040 (ADB 2023b). To ensure and promote inclusive benefits, there is a need to invest in putting in place safeguard measures to address misuse of technologies. In the agri-food sector, the spread of mobile technologies, remote-sensing services and online marketing services can improve smallholder farmers' access to information, inputs and good prices increasing production, streamlining supply chains and reducing operational costs (Townsend et al. 2019).

The region needs innovative approaches to access climate investments by improving its environmental performance so that it can attract private environmental, social, and governance investments, resulting in lower costs for sustainable debt (IMF 2024).

Table 20.4: A Recycling rate for different materials

Variable	Scenario	2020 %	2030 %	2024 %	2050 %
Aluminium	Behaviour-Focused	60	62	63	65
	Current Trends	60	60	60	60
	Technology- Focused	60	66	73	80
Copper	Behaviour-focused	48	50	51	53
	Current Trends	48	48	48	48
	Technology- Focused	48	54	61	68
Industrial Roundwood	Behaviour-focused	40	42	43	45
	Current Trend	40	40	40	40
	Technology- Focused	40	46	52	60

Sand Gravel and Rock for Construction	Behaviour-Focused	70	72	72	75
	Current Trends	70	70	70	70
	Technology- Focused	70	76	83	90

20.5.2.6.2 Implications on environmental systems and unintended consequences

Adoption of technological solutions alone could drive prices high, leading to poorer access to a healthy diet and adequate food to poor and vulnerable groups. To cope with the climate crisis, food system transformation can focus on conservation-based intensification of agriculture and reducing excessive use of chemical fertilizers and pesticides in the region. Sustainable transformation of the food system must rely on green manures, methane-reducing animal feed, financial incentives such as support for certification and labelling that promotes ecological and environmentally friendly farming while eliminating harmful subsidies that encourage over-fertilization (FAO 2021).

The Asia and the Pacific region's success in increasing its forest area, countering global decline through large-scale reforestation in large economies, needs to be kept apace. Emerging challenges including deforestation, forest degradation, overexploitation of natural resources, and spikes in poverty need

Box 20.3: Climate change adaptation needs

The Asia and the Pacific region needs to prepare for adaptation to climate change and related disaster risks, as the region accounts for almost half of global natural and human-induced disasters. The expansion of informal settlements in urban areas needs to be protected from increasing urban heat island effects. Increased climate and weather extremes may further cause serious damage to local infrastructure, which in turn affects human security. (Chapter 8). This can be overcome by building climate-resilient infrastructure, using microgrid energy systems, water recycling systems, and local farm and food supply chains. Nature-based solutions can protect communities and infrastructure from coastal flooding and provide the evacuation space and sufficient ecosystem services that can potentially support to provide the human basic needs to all residents (**Figure 20.10**)

Figure 20.10: Nature-based solutions for coastal flood protection and ecosystem services provision

to be addressed through green, inclusive and resilient development actions. The estimated 500 million hectares of deforested and degraded land in Asia and the Pacific can be rehabilitated through ecosystem restoration (FAO 2023b). Transformative change is essential to address deforestation and ecosystem degradation caused by slash-and-burn and monoculture agriculture – practices driven by poverty and unsustainable lifestyles (FAO 2021; IPCC 2022).

20.5.3 Behaviour-focused Transformation Pathway

The behaviour-focused transformation pathway responds to policy questions by driving societal shifts towards sustainability, emphasizing equitable access to clean energy and ecosystem services. Using this approach, Asia and the Pacific region can transform its climate, nature and environment actions

through cross-sector, cross-scale and interdisciplinary solutions tailored to the region and subregions as described below.

20.5.3.1 Transition to green energy

In the Asia and the Pacific region, the renewable energy penetration in primary energy supply mix (**Figure 20.6**) is projected to increase about six times between 2020-2050 with 35 per cent of non-biomass renewables share by 2050 (Chapter 11). The adoption of renewable energy would also grow as more consumers start acting as prosumers, contributing energy to the grid. Demand side measures driven by lifestyle changes would drive the energy transition (KPMG Asia and the Pacific 2022), leading to decline in primary energy supply (11.3.1).

To increase electricity access, especially in rural and remote areas, establishment of decentralized energy systems with storage is essential (Asif et al. 2024, UNESCAP 2012), which could be further enabled by active and inclusive local governance that facilitates increased participation of all users especially women. Distributed electricity storage such as rooftop solar is expected to gain traction in coming years.

Concerning cooking fuels, the incremental demand in the Asia and the Pacific region is expected to be increasingly met by LPG to replace biomass and kerosene. For switch to LPG, the transition cost could be supported through government subsidies on cylinders (Sharma et al. 2019). In rural areas, increased adoption of efficient cook stoves and smaller size LPG cylinders could accelerate the transition (Gould et al. 2020). To promote electric cooking, free or subsidized electric cook stoves and associate utensils could be provided. Alternate technologies such as biogas could also be promoted to expand the clean energy basket, where local governments play major role.

The transition progress in Pacific Island countries could be accelerated using Indigenous Knowledge and local practices, such as Talanoa and Talanga, Tongan processes for participatory decision-making during project planning (Ofanoa et al. 2015; UNFCC 2022; Park et al. 2023; Chapter 11).

The final energy consumption in behaviour-focused pathways is expected to be less by about 43 per cent in 2050 in comparison to technology-focused pathways, as people are expected to adopt less-energy-consuming lifestyles, in the form of public transportation, judicious consumption, and increased use of recycled and reused materials. (Chapter 11, Chapter 16).

20.5.3.2 Sustainable agriculture and food system

Behavioural changes play a significant role in transforming the food system in the AP (FAO 2021), and the population at risk of hunger will likely fall after 2020 to just 1.06 million in 2050 (**Figures 20.7**; **20.8**). This may be attributed to the promotion of vegetarian and vegan diets that counter the expected rise in the consumption of meat and dairy products that accompany AP's growing middle class (FAO 2021). Reducing food waste is also vital to food system transformation in this pathway. These solutions include rearing regionally appropriate livestock on pasture, reusing food waste for nutrient recovery through backyard composting in rural towns, and connecting small-scale farmers with supermarkets through government-sponsored interfaces and services (FAO 2022b).

A strong commitment to developing supportive policies, market tools, and good governance to promote biodiversity-based practices, Indigenous knowledge, and local expertise in food production will drive the transformation of the food system along this pathway.

Effective governance and climate-resilient practices in the aquatic-food systems are crucial for ensuring food security and livelihoods (FAO 2023). The region can retain the position of being world's largest aquaculture producer, contributing 92 per cent of the world's supply of farmed fish and other aquatic products by maintaining resilience (FAO 2023a). To ensure sustainable growth, it's essential to curb overfishing through sustainable aquaculture intensification and expansion, manage all fisheries effectively, and upgrade aquaculture value chains. In this regard, implementing measures such as ecosystem-based fisheries management and controlling illegal fishing can help protect marine ecosystems and ensure food security in the Asia and the Pacific region (Fabian et al. 2023). Meanwhile, in the Small Island Developing States (SIDS) of the Pacific, a growing number of entrepreneurs are developing ideas such as smartphone apps, which help

Credit: crshelare/Envato

producers and consumers make informed, nutritious choices {17.2.1-17.2.5}.

20.5.3.3 Circular Economy and pollution control and prevention

A mix of regulatory measures, knowledge and good practice-based advocacy, awareness building for behavioural change can help make a huge shift in personal and organizational actions. Countries can mobilize younger generations in eco-friendly waste processing behaviour by incorporating this aspect in college education and transforming students, as enlightened future leaders, bring strong social impacts of pro-environmental behaviours to both the young and elderly citizens, while individuals' behaviour of household waste separation also matters highly (Rieckmann 2018).

Appropriate behavioural change needs to be adopted to promote citizen engagement for managing the waste at its source. Informal waste pickers can be organized by collecting segregated waste and separating recycling materials and working with local government in waste segregation. Improving the adoption of circular economy standards and practices

needs effective collaboration across various sectors and among all member economies.

Business sectors could coordinate with the upstream supply network, lobbying the government, and raising public awareness, while for local communities, there is a need to create mass awareness on the need for waste segregation and environment friendly disposal {15.2}.

20.5.3.4 Economic and financial system reforms

Countries in the AP region can accelerate climate and biodiversity action by integrating them into national finance systems. The reform can provide incentives to the private sector and set standards for emission disclosure by companies and products (OECD 2021). While strengthening disclosure systems, leveraging the pressure transmitted through supply chains to encourage collaborative carbon reduction between companies and their suppliers can gradually become a policy trend.

Several nations in the AP region have prioritized electric mobility and the reduction of carbon emissions in their transportation sectors. Forecasts from the International Energy Agency indicate that the total number of electric vehicles, encompassing cars, vans, trucks, and buses, could surge to 200 million in the region by the year 2030. However, with ambitious climate policies and financial incentives in place, this figure could potentially climb to 350 million, thereby making significant contribution to the worldwide ambition of reducing emissions (IEA 2022a){14.3-14.6}.

20.5.3.5 Conservation and restoration of nature

Integrating climate-resilient agroforestry, sustainable forest management, and conservation agriculture practices using Indigenous and local knowledge can improve ecological integrity of both agriculture and forest ecosystems (FAO 2023). Sustainable forest management and conservation agriculture programmes provide significant carbon sequestration sinks while also benefiting Indigenous Peoples and local communities. The land-sea ecosystem conservation requires integrated management and restoration plans informed by Indigenous Knowledge and Local Knowledge (UNEP 2022a). Effective management of protected areas can prevent land degradation, protect critical biodiversity areas, and help meet the Kunming-Montreal Global Biodiversity Framework targets {18.2.1-18.2.3}.

Growing numbers of nature-based solution pilot cases offer insights for potential adoption in the Pacific Small Island States. Ecosystem-based adaptation is widely recognized in the Asia and the Pacific regions as sustainable approaches to climate change adaptation. The effective use of these tools streamlines the decision-making process for planning ecosystem-based adaptation initiatives at local levels, making it easier to integrate these strategies into practical actions and behaviour (GIZ 2024).

The Asia and the Pacific region has emerged as a vibrant hub for environmental and social entrepreneurship, with a surge in initiatives addressing environmental problems. From green technologies and climate-smart practices to ventures led by women and youth, innovative solutions are flourishing across the region (**Box 20.3**).

20.5.3.6 The implications of the transformation

20.5.3.6.1 Socioeconomic system

The maintenance of decentralized energy systems in remote and rural areas, can increase employment opportunities, especially for women, who often lack good access to education and training due to cultural norms and lack of childcare support.

Countries can fast-track their net-zero and circular economy strategies to significantly affect international trade. The shift towards a low-carbon economy will directly influence resource demand, particularly reduce fossil fuel consumption and boost demand for low-carbon technologies (Yang et al. 2023). Tax incentives and policies encouraging research and development can accelerate low-carbon technology development, fostering sustainability.

20.5.3.6.2 Environmental systems / unintended positive and negative consequences

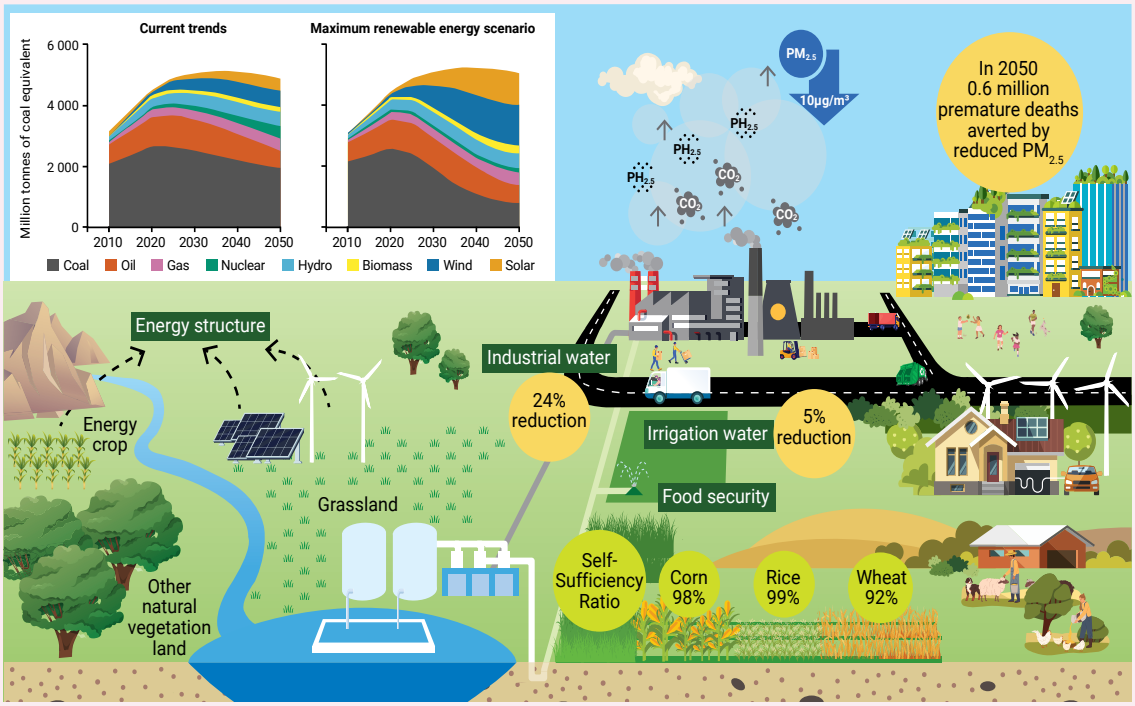
On the consumer side, products with lower environmental footprints or items made from recycled

materials can positively influence market trends and encourage businesses to adopt more sustainable practices. By adopting more sustainable practices, such as reducing, reusing, and recycling, communities can decrease the demand for new resources, thereby reducing the resource pressure on the Earth system. For instance, the efficiency of nitrogen resource use would increase from roughly 39 per cent in 2020 to almost 50 per cent by 2050 (Congreves et al. 2021). On the product side, increased recycling and better management practices are expected to reduce the waste released into the environment.

Restoring degraded ecosystems and undertaking large-scale reforestation efforts can help combat biodiversity loss and climate change in the region. These activities can contribute to carbon sequestration, enhance habitat connectivity, and provide multiple benefits to local communities (FAO 2023b). According to the IPCC (2022), a 40-70 per cent reduction in greenhouse gas emissions could be achieved by 2050 along with these behavioural changes.

20.5.4 What does that mean for the regional priorities?

By using model outputs and literature synthesis, mega-trends and policy options of major environmental issues in the region and subregions are analysed. Transformation pathways – based on Current Trends and Technological-focused and Behaviour-focused transformation scenarios – can reach subregional scale wherever data and information support are sufficient (UN 2023). Most countries in the region show continuous transformation, either in technology or behaviour, or both. Following the Current Trends Scenario is not an option. Technological transformation shapes resilient urban infrastructure and smart cities, enhancing urban resilience especially in major urban clusters of North, South and South-east Asia, accelerating transitions to renewable energy sources, amplifying energy efficiency, and promoting sustainable transportation that can significantly reduce greenhouse gas emissions in the region (ADB 2023a). Digital technologies including big data, artificial intelligence, and incorporation of citizen science observations can provide new frontiers for environment solutions in the region, including early warning systems for disaster risk reduction, cloud-based pollution monitoring networks, and smart grids for solar and wind energy. Meanwhile, lifestyle transformation is expected to accelerate across the region, with changing land-use practices, food production and processing and dietary habits. This accelerating transformation should apply both modern and Indigenous Knowledge and Local Knowledge and good practices in decision-making processes and enhance coordination among sectors and government units. The integration of the two transformation pathways, interacting synergistically using digital technology, can enhance e-commerce in the region and lead to a fundamental shift in marketing and consumption patterns (**Box 20.4)**.



A technology-focused transformation sees energy transition driven mainly by the wide-scale deployment of renewable energies in carbon neutrality scenarios. Non-fossil energy will gain a more than 75 per cent share of total primary energy by 2050, growing from only around 17 per cent in 2020. This jointly reduces air pollution and brings human health co-benefits by avoiding 0.6 million air pollution-related premature mortalities in 2050. The West-East Energy Transfer project holds promise for future energy distribution in China, bringing significant benefits to the more densely populated and economically developed eastern and central China. Meanwhile, achieving carbon neutrality will also result in a 24 per cent reduction in the country's industrial water consumption by 2060, as renewable energy sources replace water-intensive thermal plants.

In the behaviour-focused transformation, rural residential energy for cooking and heating is shifted towards a two-stage energy transition from coal and biomass to natural gas and liquefied petroleum gas before 2040 and then to electricity by 2060. The decarbonization of cooking and heating is estimated to reduce $PM_{2.5}$ concentrations in almost all provinces and empowers individuals to contribute to reducing carbon emissions. This is particularly significant in northern China provinces, where the reduction in $PM_{2.5}$ concentrations is most pronounced. For the food system, behavioural change is essential to counter the adverse effects of land competition introduced by large-scale bioenergy deployment. Reconciling bioenergy deployment with domestic food security requires enhanced food system efficiency enabled by a bundle of sociotechnical measures including halving food loss and waste, shifting to healthier diets and, most importantly, narrowing crop yield gaps.

Box 20.4 Transformation pathways for China

The transformation pathways for China to reach carbon neutrality by 2060 are modelled using the tools recommended in Chapter 9 (**Figure 20.11**). Achieving carbon neutrality in China reveals plentiful opportunities to realize synergies in the water-energy-food nexus and the health sector. However, both technology and lifestyle transformations are needed to yield these gains while reducing consequences for land use and food security. This calls for more carefully designed strategies for China, which could also provide valuable insights for countries in the Asia and the Pacific that share similarities with some provinces in China.

Figure 20.11: Carbon neutrality transformation pathways for China and its implications for energy, environmental and food systems

2.5.5 Reflections on strengthening regional interlinkages

2.5.5.1 Interlinkages

By embracing transformative pathways, the Asia and the Pacific region can achieve global goals and targets for addressing climate change mitigation and adaptation, nature conservation, and waste management – driven by factors including demographic dividends, labour-force mobility, decarbonized urbanization and industrialization, and climate-resilient development. These changes can result in mostly positive environmental consequences with notable improvement in ecosystem health, biodiversity, water resources, and human well-being (UNESCAP 2019). Protecting environment and conserving nature through ecosystem-based adaptation can result in human security and resilience of most vulnerable countries, especially climate-change-vulnerable small island nations in the Pacific region. Flood defences in the coastal areas and building resilient infrastructure and livelihoods can avert the risk of permanent submergence of island and coastal settlements (IPCC 2022; IPCC 2023).

To combat the global environmental crises, countries in the region can double their efforts towards sustainability and environmental conservation. A renewable energy transition can lead the transformation by providing affordable access to low-income communities.

However, despite these potential achievements, significant challenges remain, especially in finance, necessitating urgent action to address the complex developmental and environmental challenges in the region and subregions.

The Current Trends Scenario results in a two-fold increase in CO_2 emissions by 2050, justifying an urgency for transforming environmental and economic systems. Nature-based solutions, sustainable aquaculture and agriculture practices, and nature conservation efforts are necessary for creating resilient food, water and human systems. Efficient waste management, recycling, and tackling e-waste are crucial for sustainable materials management (Peng et al. 2023). Environmentally sound investments and green technology innovation are key strategies for economic growth while addressing environmental challenges (United Nations Framework Convention on Climate Change [UNFCCC] 2023). Multiple transformation pathways are likely to be adopted by the region's countries in the coming decades leading to 2030 and 2050 when SDGs are to be achieved. These pathways are likely to be interlinked, creating interdependence for maximizing synergies and minimizing trade-off.

20.5.5.2 Synergies and trade-offs

Technological advances, including smart-grid systems and energy-efficient appliances, complement sustainable consumer behaviours by enhancing efficiency and facilitating practices like recycling and waste reduction. This synergy can build resilience against climate impacts, as innovations in climate-resilient infrastructure work alongside responsible land use and biodiversity conservation efforts. Furthermore, the integration of technology and behavioural change can create new job opportunities in sectors like renewable energy, stimulating economic growth and establishing a positive feedback loop that benefits both the environment and the economy.

However, there are notable trade-offs to consider. Transitioning to new technologies often involves significant upfront investments that may burden lower-income communities and disrupt traditional industries, leading to job losses. Additionally, disparities in access to technology can exacerbate socioeconomic inequalities, while reliance on technological solutions might foster complacency regarding sustainable behaviours. Moreover, competition for limited land and water resources due to the introduction of new technologies may conflict with food production and ecosystem health goals.

Balancing these synergies and trade-offs is crucial for effective policymaking. By strategically navigating the interactions between technological innovations and behavioural changes, stakeholders can design interventions that drive sustainable development in the AP region and beyond. This holistic approach can foster resilience and inclusivity while addressing complex challenges such as climate change, unsustainable resource management, and economic disparity.

20.5.6 Policy implications

The region can enhance sustainable development by implementing a range of policies focused on renewable energy, sustainable land and water management, and the transformation of food systems. Key strategies include incentivizing renewable energy adoption through smart subsidies and feed-in tariffs, promoting sustainable food systems to adapt to and address land degradation and climate extremes, while ensuring equity and justice. Additionally, supporting innovative financing models and fostering public-private partnerships can increase investments in green sectors.

On the consumer side, products with a lower environmental footprint or items made from recycled materials can positively influence market trends and encourage businesses to adopt more sustainable practices. Meanwhile, significant behavioural shifts, alongside technological advancements, could help achieve net-zero emission targets of the region by 2050. As individual investors grow more environmentally aware, their investment activities are likely to shift away from resource extractive industries and towards sectors that promote sustainability and circular economy models.

Restoring degraded ecosystems and undertaking large-scale reforestation efforts are vital for combating both biodiversity loss and climate change. Creating more green parks and open spaces, wetlands, and urban agriculture can counter flood risks and urban heat island effects.

Table 20.5: Actions for Asia and the Pacific Countries

Systems	Technology-focused Transformation		Behaviour-focused Transformation 2024 %	
Economic and finance {14.3-14.6}	Innovative decarbonizing initiatives through market-based mechanisms	Apply novel technology for green finance	Scaled up Finance and integration of Indigenous and local solutions into modern ones	Apply carbon tax and polluters pay principles
Material and waste {15.2}	Reduce e-waste with reuse and life cycle assessment	Digital innovations for supply chains traceability	Change market and pricing signals for used products and secondary materials	Increase awareness on circular lifestyle choices
Energy {16.2-16.4}	Scale-up adoption of renewable technologies	Increased investment in electric cars and energy saving technology	Raise awareness to the benefits of lower energy lifestyles	Enable availability of sustainable mobility choices
Food {17.2.1-17.2.5}	Enhance localized technology in farming and food processing	Strengthen food market structure and regulations in international trade.	Conservation agriculture practices with Indigenous and local knowledge	Encourage local knowledge based diverse and healthy diet
Environment {18.2.1; 18.2.3}	Prioritize technological innovation for ecosystem protection and restoration	Advance digital technology for monitoring and forecast	Coordinate nature-based climate and ecosystem solutions	Climate-resilient agroforestry, sustainable forest management

20.5.7 Conclusion

The outlook for the AP region presents a mixed picture. With the Current Trends Scenario, the region will not achieve the sustainable development goals nor fulfil net-zero ambitions by 2030 and 2050, respectively. However, by undertaking transformative actions the region can accelerate progress by capitalizing on its fast economic growth, advanced technological innovation and regional cooperation. Greater and diverse challenges exist at subregional levels to embrace transformation – the East Asia and West Asia subregions provide promising outlooks, in addition to a few fast-growing economies in the South Asia and Southeast Asia subregions. Therefore, sub regionally customized transformative options can address the global environmental crises. What is critically needed is striking a strategic balance between socioeconomic growth and sustainability through a judicious application of diverse knowledge systems, technology and behavioural change options.

20.6 Eastern European Region

20.6.1 Introduction

Eastern Europe (EE) is part of the fastest warming continent in the world. Climate risks are threatening energy and food security, ecosystems, infrastructure, water resources, financial stability and human health (European Environment Agency [EEA] 2024). The region's key priorities are:

- Climate change
- Land degradation
- Heavy fossil fuel usage and abusive pricing generating high levels of energy poverty
- Loss of biodiversity and key habitats (Chapter 8)

This chapter proposes transformative pathways to meet these priorities, providing recommendations to

the region's policymakers to achieve environmentally sustainable, socioeconomically sound, and climate-resilient futures by implementing solutions that optimize synergies and trade-offs. Most of the region's countries are either European Union (EU) member states, candidate countries, or partnership countries that follow EU legislation and policies. Non-EU countries follow their national policy and regulatory frameworks. The war in Ukraine is a major factor affecting the future of the region's ecosystems and environments (UNGCRG 2022; UNEP 2023). Analysis and policy recommendations for the future, presented in the next sections, answer this Chapter's policy questions, based on modelling results and a literature review and with specific input from Indigenous Knowledge and Local Knowledge experts.

20.6.2 Technology-focused Transformation Pathway

20.6.2.1 System transformations

This pathway focuses on technology solutions to drive systemic change across energy, agriculture, and materials sectors.

The region is influenced by EU policies. However, climate neutrality targets are to be achieved at different speeds depending on expectations for each country. Russia and Belarus follow different legal frameworks to achieve global goals and targets (Lafortune et al. 2022; Bashmakov 2023; Interreg Europe 2023; Nurcan Kilinc-Ata and Dolmatov 2023; IRENA 2023a-e; European Commission 2023a-h; Energy Monitor 2024; Yakov and Partners 2024; Climate Action Network Europe [CAN] 2024; IEA 2025).

Under this scenario, the transformative, integrative and cross-sector solutions tailored to the needs of the region are described below:

20.6.2.2 Economic and financial system reforms

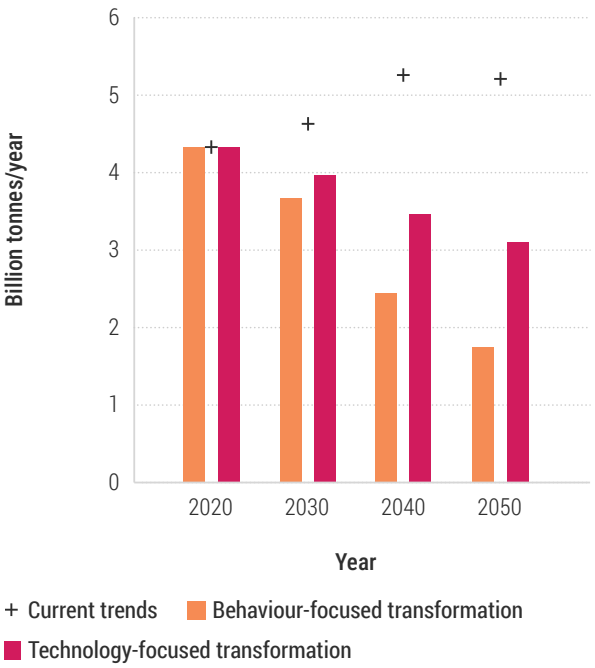
The EE region needs tighter environmental regulations for foreign direct investments, to combat foreign investors' interest in profit maximization and promote the use of green technology for environment protection. Governments can provide incentives for adopting clean technologies to enhance renewable green infrastructure, reduce economic and energy poverty, and create job opportunities (Simionescu and Gavurová 2023; European Commission 2023a-h; Chapter 7). The region recorded progress on sustainable and digital finance, which must be intensified. By 2030, green finance will contribute to reductions in carbon emissions and material footprints – this trend will accelerate between 2030 and 2050 (European Commission 2023a-h; Kantor et al. 2023; UNDP 2023). Innovative green finance and carbon tax measures will boost investments and consumption towards sustainability (Chapter 14). The national legal framework alignment to EU banking requirement is ongoing in most EE countries, Russia manages to keep its green finance agenda relevant, while Belarus facilitates green finance development collaborating with UNDP (Kopalkina and Arustamyan 2024; Martirosyan 2024) {14.3-14.6}.

20.6.2.3 Circular economy, pollution control and prevention

Most of EE countries focus on managing waste rather than on preventing it through circular design. It is expected that a 23 per cent circularity rate target will be achieved by 2030 (European Court of Auditors [ECA] 2023). Russia and Belarus follow different legal frameworks to achieve national targets, mainly in the waste sector (Maalouf et al. 2021; Republic of Belarus 2024). The technology-focused pathway generates a decrease in total material demand through improved design, material substitution, a high recycling rate and reduced waste (Chapter 15) (**Figure 20.12**). **Figure 20.12** Total material demand scenarios in Eastern Europe (Chapter 11-12).

To achieve the transition to a circular economy and climate neutrality by 2050, binding targets, which only exist in the waste sector – municipal waste, construction and demolition waste, and the deposit return system – must be introduced in all sectors (Gassiy and Novikov 2022; National Recovery Council 2022; United Nations Conference on Trade and Development [UNCTAD] 2022; European Commission 2023a-h; Bitsadze 2023; Barseghyan 2023; EU4Environment 2023; Todasca 2023; European Union 2025). The technology-focused pathway reduces demand for industrial roundwood by 11 per cent between 2020 and 2030 and by 25 per cent between 2020 and 2050, providing opportunities for improvements in conservation and ecosystem service (**Figure 20.13**) {15.2.5}.

Figure 20.12: Total material demand scenarios in Eastern Europe



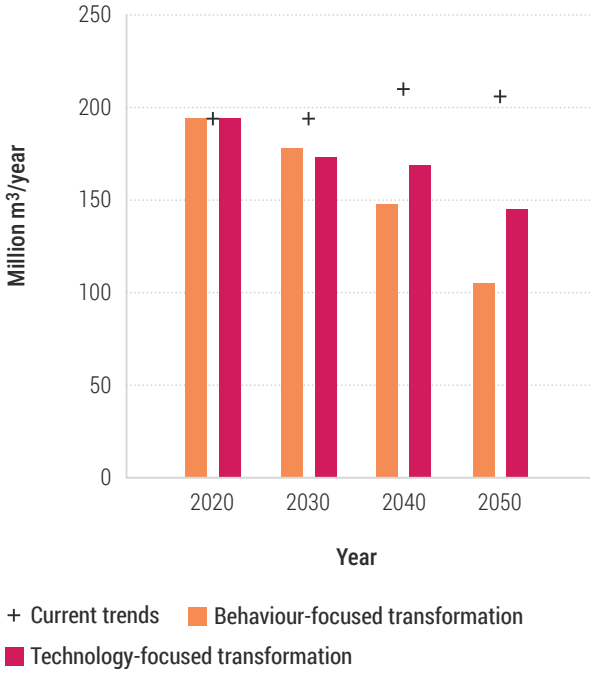


Figure 20.13: Forestry production scenarios in Eastern Europe

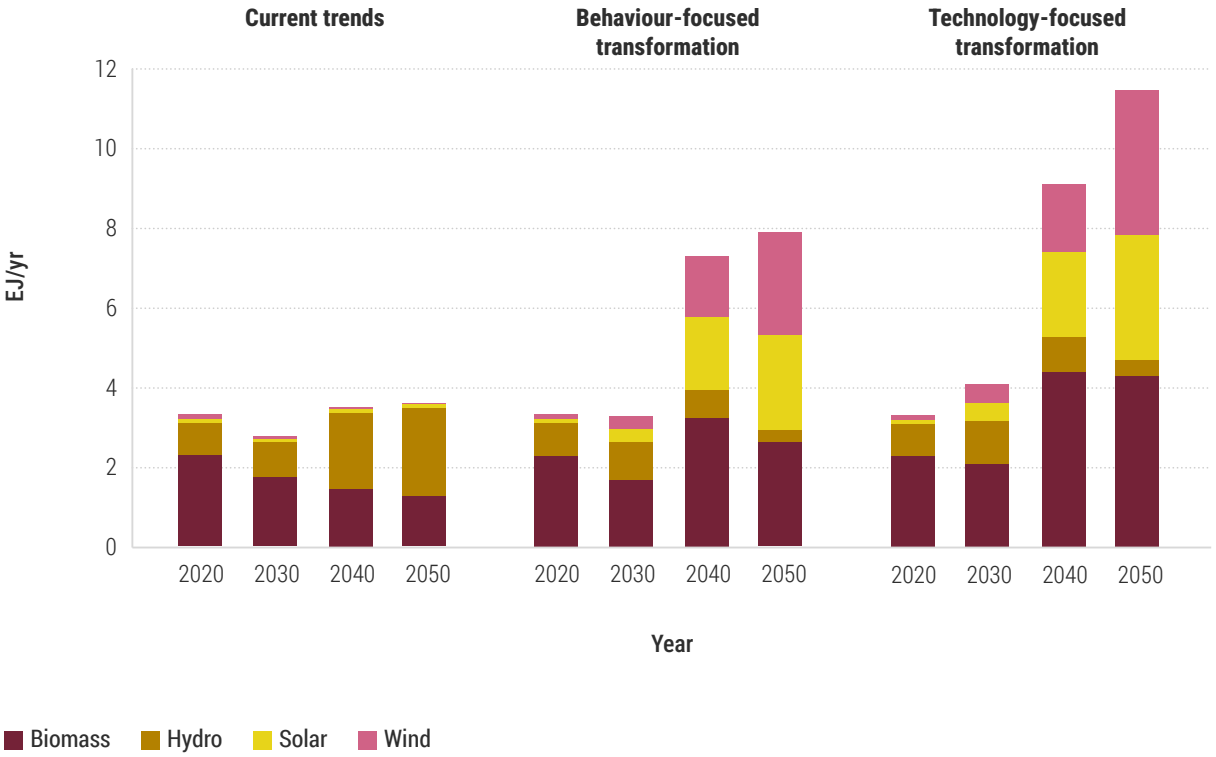
20.6.2.4 Transition to renewable energy

Different policy frameworks for EE countries explain the uneven nature of low-carbon energy transitions (International Renewable Energy Agency 2023; IRENA 2023a-e; European Commission 2023a-h; Energy Monitor 2024; Yakov and Partners 2024; Eurostat 2024; IEA 2025). An energy transition is completed by 2050 based on a transition to renewable energy, carbon capture and storage (CCS) strategies and enhancing energy efficiency (Chapter 11).

In this scenario, primary energy production declines by 28 per cent between 2020 - 2030 but rises by 19 per cent between 2030 - 2050 due to the rapid increase of renewable energy use. Production of renewables is expected to rise sharply between 2020 - 2050. Solar energy production could increase by 468 per cent between 2020 and 2050 (**Figure 20.13**). Nevertheless, the share of renewables as a proportion of the total primary energy supply remains relatively low, at 27 per cent by 2050. Meanwhile the fossil energy supply share declines slowly by 2050, therefore promoting CCS as a solution to climate change is essential (**Figure 20.14**; Chapter 11-12; 16.2-16.4).



To reach EU Renewable Energy targets (2030–2050) for improving the environment, public health, and reducing energy poverty, the EE should implement the following policies:

- Expanding renewable energy while phasing out fossil fuels
- Utilizing the EU Social Climate Fund and emissions trading systems revenues to lower energy bills, promote clean transport, and invest in energy-efficient housing across regions' most in need
- Breaking energy monopolies and regulating unfair pricing
- Preventing speculative trading in energy markets; (European Commission 2023i; Widuto 2023; European Environmental Bureau 2024)

20.6.2.5 Sustainable Agriculture and Food System

The technology-focused pathway is based on efficiency, sustainable intensification, and precision farming (Chapters 16 to 18). A shift towards sustainable diets is promoted through nature-based solutions and new production techniques boosting the introduction of novel foods. Digital agriculture and

Figure 20.14: Renewable energy supply scenarios in Eastern Europe

biotechnology pose a significant barrier to small and medium enterprises facing difficulties in innovating (European Economic and Social Committee [EESC] 2022; European Academics Science Advisory Council [EASAC] 2022; Masi et al 2023; Konfo et al. 2023).

By 2030 in most EE countries, the economy will remain heavily reliant on the agricultural sector in terms of contribution to GDP and total employment, while small-scale agriculture will continue to be an important food source and safety net (Eurostat 2022; Yakovlev and Alexseev 2022; IPCC 2022; European Commission 2023a-h; The GlobalEconomy.com 2023a-d; Eurostat 2024). Extreme weather events and political instability will continue to threaten food security in several subregions of the EE.

Demand for food crops increases by five per cent by 2030 and 14 per cent by 2050 compared to 2020. By 2030 and 2050, demand for livestock declines by one per cent and 15 per cent, respectively, while demand for feed crops by seven per cent and 24 per cent reflecting a shift towards sustainable diets promoted by nature-based solutions, new production techniques for novel food and higher crop yields. However, demand for energy crops records a sharp increase with 473 per cent by 2030 and 546 per cent by 2050). Increasing crop yields offsets this effect (**Figure 20.15**; 17.2.1-17.2.5).

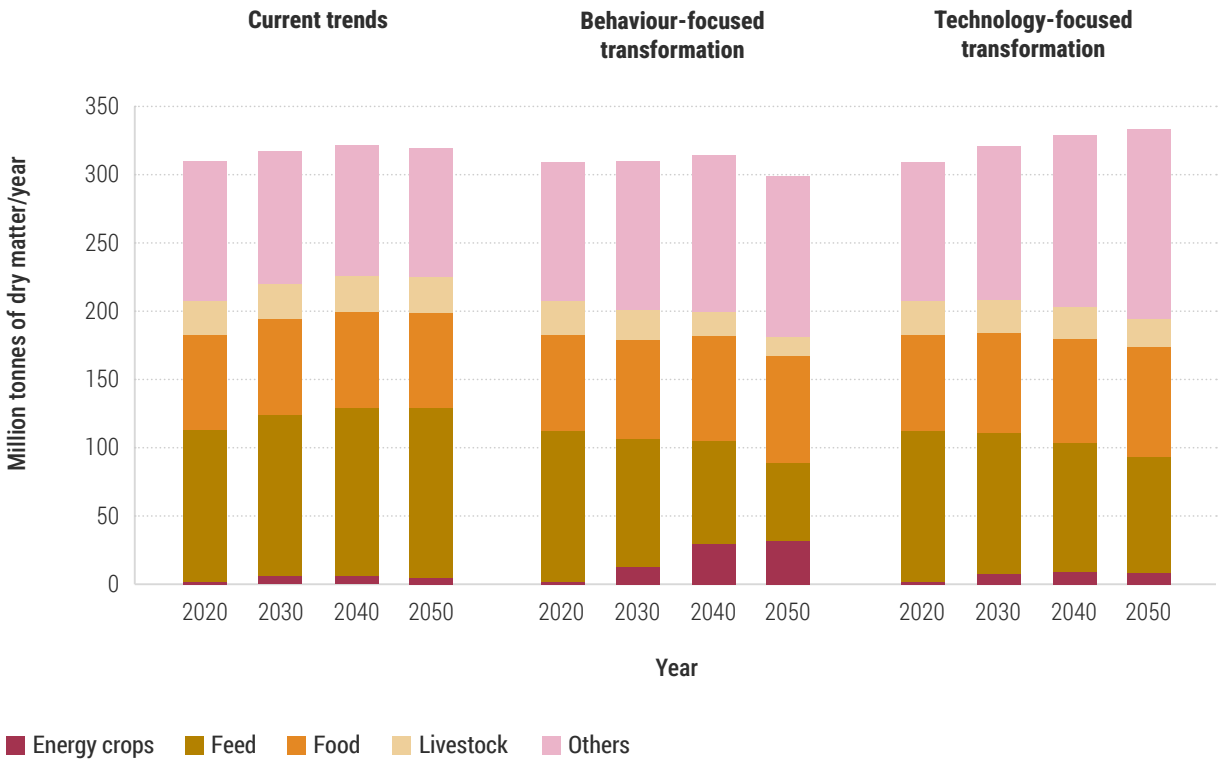
Due to high efficiency, precision farming and reducing food waste, this scenario generates the highest increase in agricultural production, by 13 per cent between 2020 - 2030 and by 41 per cent between 2020 – 2050 (**Figure 20.16**) The region's agricultural production exceeds demand leading to trade surplus between 2020 and 2050. Sustainable food system transformations can be achieved under this pathway.

20.6.2.6 Conservation and Restoration of Nature

Generally, EE follows the EU Biodiversity Strategy for 2030 by protecting nature and reversing the degradation of ecosystem, while Russia and Belarus have different legal frameworks and coordinate biodiversity strategy with global goals and national targets (Elias 2021; EASAC 2022; EEA 2023; Republic of Belarus 2025).

Numerous sites in EE – mining areas, heavy industry zones, contaminated lands – require revitalization, where principles of natural succession must be applied to achieve a higher quality of future ecosystems (Chapter 8). The level of biodiversity is significantly

Figure 20.15: Agricultural demand scenarios in Eastern Europe



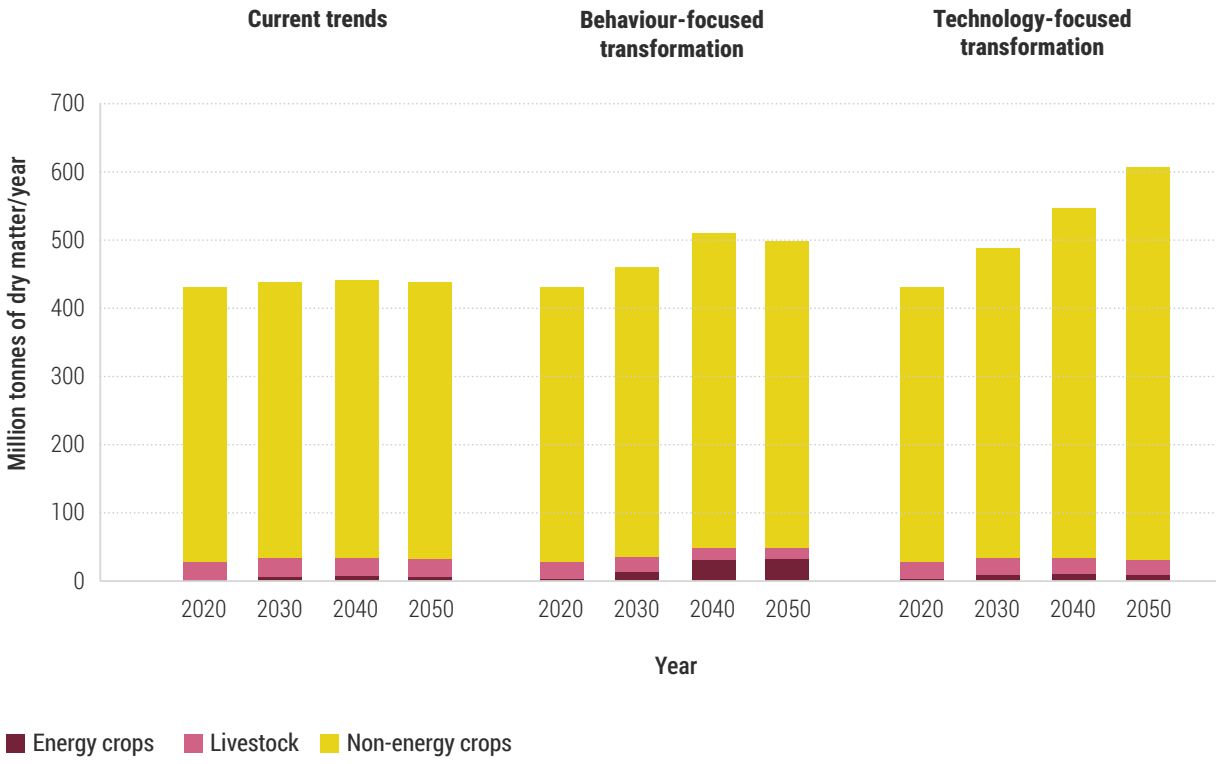


Figure 20.16: Agricultural production scenarios in Eastern Europe

higher compared to other regions of the world. A trend of further reduction in mean species abundance is projected by 2030 (Chapters 11 and 12). Sustainable agricultural practices contribute to mitigate land degradation, biodiversity loss and climate change, aligned to the EE priorities (Chapter 8).

The technology-focused pathway generates an increase in cropland cover, with two per cent by 2030 and 10 per cent by 2050 due to the rising demand for energy crops. Forest cover records no change by 2030 and one per cent increase by 2050. Pastureland decreases by nine per cent by 2030 and by 33 per cent by 2050, due to a shift towards sustainable diets promoted by nature-based solutions and new production techniques. By managing cropland expansion, this scenario can mitigate land-use changes, enhance biodiversity conservation, and support sustainable farming {18.2.1; 18.2.2}.

20.6.2.7 Implications of the transformation

The EE region is shifting to digital applications quickly (McKinsey and Company 2023). The technology-focused pathways offer substantial benefits, including economic growth, jobs creation, improved human well-being, resource efficiency and waste minimization. While technology-focused pathways can create new jobs in high-tech and service sectors, they may also generate unintended negative consequences and displace workers in traditional industries, leading to higher unemployment, informal employment, brain drain, high old-age dependency and income inequality, if adequate retraining is lacking. Targeted investment in education and training promoting green and digital skills can bridge income inequality gaps and enhance workforce adaptability (Simionescu and Gavurová 2023).

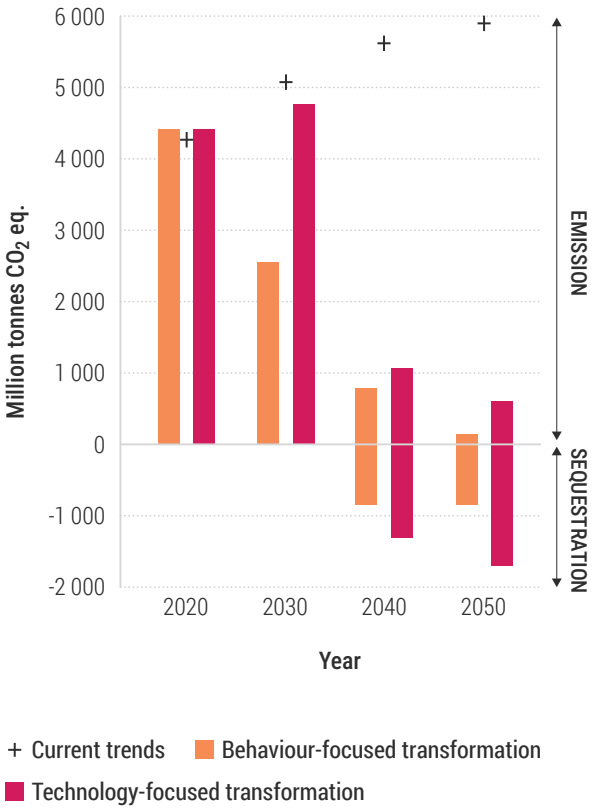
In these pathways, continued heavy fossil fuel use to 2050 would require large-scale industrial CCS deployment – including capture at power plants, industrial facilities, and direct air capture – to achieve CO_2 reduction targets of 37 per cent by 2030 and 86 per cent by 2050 (**Figure 20.17**). While afforestation and ecosystem restoration are important complementary sinks (20.7.2.6), their potential is addressed separately within the biodiversity framework. The reductions presented here therefore assume CCS as the primary offset technology, which would require a massive scale-up beyond today's capacity and must be combined with natural sinks and systemic reforms to be sufficient.

A portfolio of solutions — CCS + renewables + forest expansion + governance reforms — is required to meet the 2030 and 2050 targets.

Compared to the Current Trends Scenario, both transformation scenarios foresee lower GDP loss from climate damage which will increase by less than one per cent of GDP by 2050. Meanwhile avoided damages, measured as a percentage of GDP, are also expected to reach one per cent by 2050. According to the GEO-7 data modelling procedures, both scenarios are projected to follow the same trend (**Figure 20.18**). Internalizing damages associated with carbon emissions can encourage decarbonization in addition to the implementation of the Emissions Trading Systems and the EU Carbon Border Adjustment Mechanism.

The two pathways are not modelled as concurrent or competing simulations but as distinct and complementary strategies.

Figure 20.17: Net-emission of Kyoto greenhouse gases for scenarios in Eastern Europe



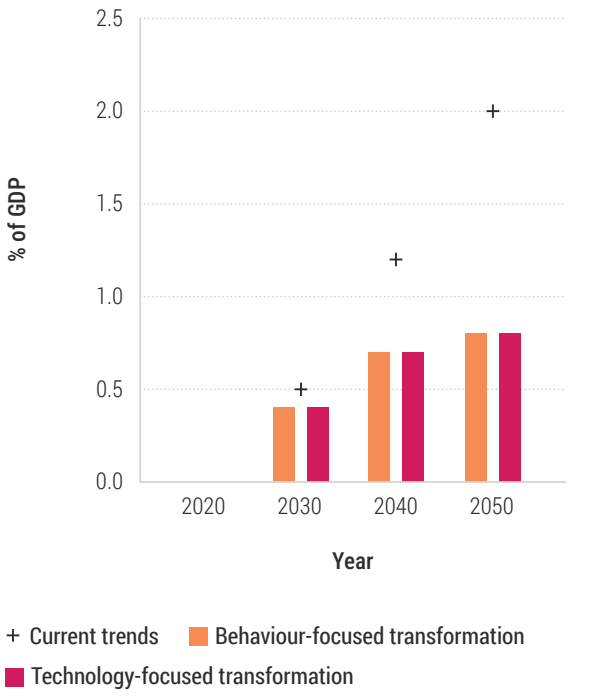


Figure 20.18: Climate damage corrected by loss relative to GDP in Eastern Europe

Source: CCCCCCC

The five systems are interdependent, and achievements in one generate co-benefits for the others. Implementation of new technologies can shape individuals' and firms' behaviour and consumer decisions, while behaviour-driven change can create demand for clean and efficient technologies.

Overall, the technology-focused pathway delivers innovations – such as renewable energies, precision agriculture, and circular production – to address regional priorities, whereas the behaviour-focused pathway reinforces sustainable consumption and social norms.

Taken together, these pathways provide independent yet synergistic solutions that mitigate Eastern Europe's environmental challenges and support achievement of the modelled targets.

20.6.3 Behaviour-focused Transformation Pathway

20.6.3.1 System transformations

This pathway emphasizes behaviour change, social norms, and community-driven actions, focusing on local and individual-level actions to drive transitions. Examples include prosumer activities and decentralized renewable energy solutions fostering community-based renewable energy generation and consumption, reducing energy poverty, dependence on centralized systems and enhancing local resilience. It also responds to policy questions by driving social shifts towards sustainability emphasizing equitable access to energy.

The behaviour-focused pathway offers transformative, integrative and cross-sector solutions and policy recommendations tailored to the EE region and are presented below.

20.6.3.2 Economic and financial system reforms

Behaviour-focused pathway aims at greening the finance systems and internalizing externalities (14.3 to 14.6). In most parts of the region, EU policies and environmental regulations are applicable. For example, the Polish energy sector applies structural changes to achieve internalizing of externalities by 2050 (Kudelko 2022).

Existing EU policies and financial mechanisms are important, but EE needs solutions for the future to ensure access and effective use of financing for green economy transition (OECD 2022). Good-practice examples include better water management strategies at user level aiming at minimizing water demand (OECD 2022) and policies for green infrastructures as blue-green corridors (European Commission 2021). The implementation of nature-based solutions supporting financial mechanisms also has strong social value (Bockarjova et al. 2022) that can compensate for lower public acceptability of a transitions' high-costs.

Policy recommendations for behaviour-focused transformation may aim at communication strategies to influence social norms and behaviours and improved citizens' and small businesses' access to financial capital and investments.

20.6.3.3 Circular economy, pollution control and prevention

Repairing, refurbishing, and recycling can be the norm for the behaviour-focused pathway (Chapter 15). Material systems in EE lack mechanisms for a circular economy.

In many EE countries the circular rate of material use (EEA 2024) is lower compared to other European countries, while in some other is even decreasing. The current EU target for 2030 is 23.4 per cent (EEA 2024), while in 2021 it was 11.7 per cent.

In the behaviour-focused pathway, material demand per capita is projected to decline by 14 per cent by 2030 and by 54 per cent by 2050 compared to 2020, representing a significant reduction compared to the technology-focused pathway (**Figure 20.12**). The behaviour-focused pathway for the materials system should seek to reduce the need for conspicuous consumption that would lead to lower material footprints (Chapter 10).

The pandemic and the war in Ukraine have significantly reduced consumption of luxury goods (Statista 2024a). However, the prediction for the short and long term is a gradual increase of the EE luxury goods market (Statista 2024a).

Policy measures may focus on preventing e-waste and stimulate the related e-waste collection and recycling rate and on promoting sustainable production and consumption, coupled with lifestyle change to reduce over consumption in the importing country and environmentally friendly production in exporting countries. Efforts should be made to achieve SDG12 through better teleconnections, sustainable trade, and targeted communication strategies (Chan et al. 2018). It is worth mentioning that stopping the decline of traditional repair shops – watch repair, cobbler services, electronics, home appliance repairs – which were common in EE, is important for enabling the new societal practices of circular lifestyle choices.

20.6.3.4 Transition to renewable energy

One of the main drivers of the behaviour-focused pathway in the energy system is the emergence of prosumers – in this context, prosumers are consumers who also produce energy, typically through renewable sources like solar panels, and are encouraged by feed-in tariffs or other support schemes (Brown et al. 2020; Korsnes et al. 2024). The potential of prosumers in EE is very high (EEA 2022; IEA 2023). For example, out of 10 EU countries with highest potential electricity production by prosumers, four countries are from EE (EEA 2022).

In the behaviour-focused pathway, primary energy production could decline by 35 per cent between 2020 to 2030 and by another 30 per cent between 2030 and 2050 (Chapters 11 and 12) and the share of renewables, especially solar and wind, is projected to increase from 6.7 per cent in 2020 to 10.4 per cent by 2030 and 35.6 per cent by 2050 due to behavioural change (**Figure 20.14**, Chapters 11 and 12). The policy measures in EE may introduce incentives for decentralized green energy production that historically was lacking in the region, with Poland already rapidly implementing these changes (EEA 2022). In Eastern Europe, civic energy prosumerism is growing in popularity and value (Żuk and Żuk 2022), because it attempts to break state monopoly on energy production. Nonetheless challenges remain – particularly in terms of sociopolitical mechanisms, given efforts to maintain centralized monopoly.

However, there is a significant potential in the region to shift prosumerism from individual to collective action via establishing energy communities (Chapter 16). Solutions levers include raising awareness of the benefits of lower energy lifestyles, mechanisms to finance expansion of energy efficiency, and renewable energy facilities at household level, as well as enabling the availability of sustainable mobility choices for the public {16.2 to 16.4}.

20.6.3.5 Sustainable agriculture and food systems

Behavioural change in food systems can stimulate a strong shift to plant-based foods and promote policy incentives to preserve the vitality of local ecosystems (Chapter 13). The behaviour-focused pathway indicates significant increase in the demand for food crops by three per cent by 2030 and 11 per cent by 2050 (**Figure 20.15**), caused by shifts to more sustainable diets at the individual level.

Behavioural transformation in agriculture and food system will also affect agricultural demand inducing the decrease of crops for livestock – 11 per cent and 42 per cent by 2030 and 2050, respectively – and crops used as feed – 16 per cent and 49 per cent by 2030 and 2050, respectively – due to a switch to plant-based and sustainable diet (**Figure 20.15**). This will require change in social norms and collective actions towards achieving more sustainable food consumption and practices (Chapter 17).

The EE region is a large producer and exporter of agricultural products, especially grains (Garazha et al. 2023). However, the scope of the land allocation to traditional agriculture increases pressures on local ecosystem services. Small and subsistence agriculture should be supported and encouraged through policies and markets, rather than eliminated or transformed. The food practices in EE need to build on rich traditions of community-based local food production that can be transferred to modern settings. For example, urban farming and gardening provide possibilities for disadvantaged citizens to participate in the production of food and empower women as agents of change. The behavioural transformation can promote significant reduction of food waste in the food chain, and dietary change will tackle the obesity problem that is visible in EE {17.2.1-17.2.5}.

20.6.3.6 Conservation and restoration of nature

Behavioural change in the environmental system can be guided by the principles of sharing resources for the reconciliation of human and ecosystem well-being. Transformation pathways indicate the possibility of achieving CO_2 emissions targets by 2050 in EE (**Figure 20.17**). The behaviour-focused pathway indicates increase of cropland, by 10 per cent by 2030 and by 12 per cent by 2050 compared to current trends (**Figure 20.19**, Chapters 11 and 12). This scenario reduces pasture lands and promotes land-use practices that protect water quality and access. By expanding protected areas and reducing pasture lands, behaviour transformation addresses land degradation challenges through ecosystem conservation and water resource management achieved through nature-based solutions. In some parts of EE, the management of protected areas lacks participatory decision-making, and systematic change is needed for nature conservation models (Yakusheva 2019). This change should encompass cultural appreciation of nature, including Indigenous and local traditions. The behavioural approach also offers the potential to enhance ecosystem quality in landscapes outside protected areas, making them more resilient to climate change and weather fluctuations (Chapter 18).

Behavioural change is a bottom-up process driven mostly by individual and community actions (Chapter 10). The conceptualization of public and private environmental actions includes waste sorting as an individual action and to participating in civil advocacy a community action. Usually, individual action is stronger than community action (European Commission 2020).

In EE, environmental activism is weak both at individual and community levels compared to other European countries, creating significant obstacles for future behavioural transformation. There are significant subregional differences in terms of social inequality (UNDP 2024), and the gap between the poorest and the richest is projected to increase. This could indicate barriers to the behavioural change that would require economic sacrifices at individual level such as paying higher prices for renewable energy (Chwialkowska and Flicinska-Turkiewicz 2021).

The behaviour-focused pathway foresees transformation guided by the principles of sharing resources for the reconciliation of ecosystem and human well-being (Chapter 12; 18.2.1; 18.2.2). By 2050, this pathway could nearly eliminate CO_2 emission in EE region – 44 per cent decrease in CO_2 emissions by 2030 and 106 per cent decrease by 2050 (**Figure 20.17**).

20.6.3.7 Implications of the transformation

Methane emissions in the energy sector would decrease more compared to the technology-focused pathway due to a significant shift from energy production reliant on fossil fuels (Chapters 11 and 12). These projections can be affected by increasing CO_2 emissions generated by the war in Ukraine (Bun et al. 2024; Statista 2024b). Awareness-raising and behavioural changes are not enough to minimize carbon footprints. There is also a need for structural changes in how the food, housing, energy, and transport networks are organized (Liobikienė and Poškus 2019), as well as motivation to update vehicle fleets for public and private businesses (Stecenko et al. 2022; The European Automobile Manufacturers' Association [ACEA] 2023).

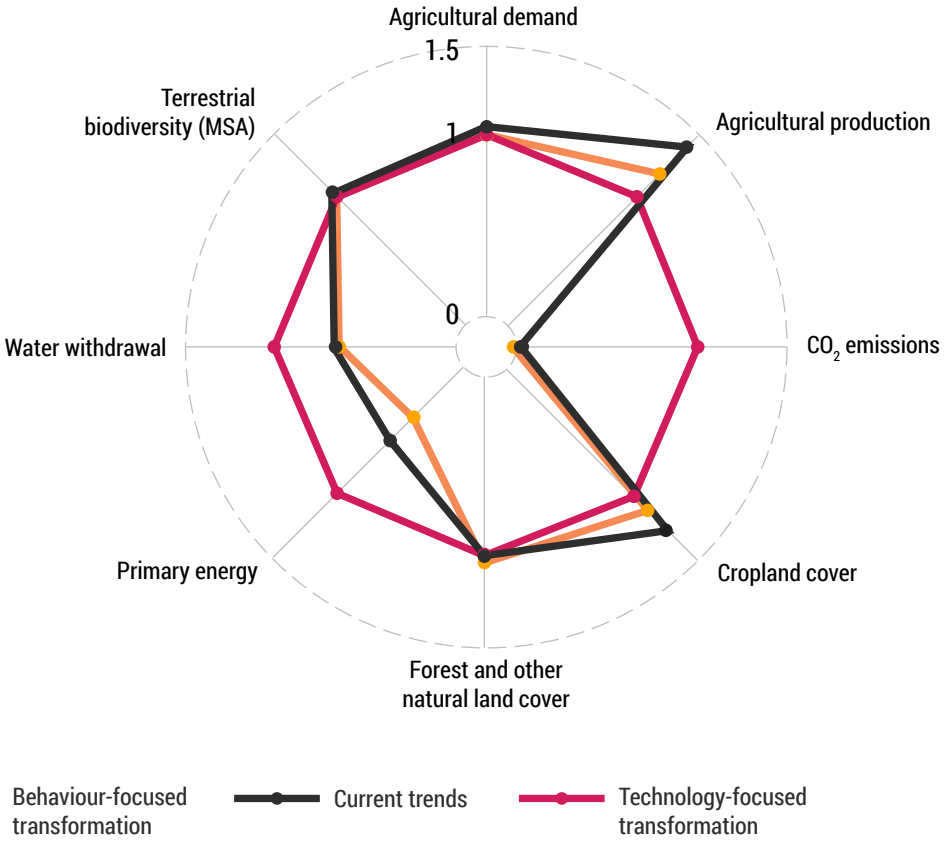
The EU's Green Deal fosters incentive mechanisms to take policy actions towards the 2050 net-zero emission target, among the EU countries in the EE region. This can play a role as motivation for taking similar actions in the non-EU region, addressing possible future regional inequalities in the scale and speed of change.

Policy recommendations should be applied to a broad range of actors, guided by strong institutions, who

engage in dialogue to explore new ways of interacting and protecting nature. Successful implementation of EU legal frameworks, directives and guidelines in member countries can act as a model for what works and adapted by non-EU countries.

20.6.4 Regional priorities

Given the unique challenges and priorities of the region, a balanced hybrid approach integrating both Technology-focused and Behaviour-focused transformations is essential to address the region's socioeconomic and environmental goals which include reducing greenhouse gas emissions, preserving biodiversity, and restoring degraded land. Each pathway offers distinct advantages but also limitations when applied independently (**Figure 20.19**).



20.6.4.1 Socioeconomic effects

A major socioeconomic challenge is EE's heavy reliance on fossil fuels (Radovanović et al. 2022), which is currently a significant source of employment and economic stability. The emphasis on carbon capture and storage technologies is crucial for the transition from fossil fuels (**Figure 20.17**). Simultaneously, behavioural changes focus more on energy use reduction. The share of EE's renewable energy (Chapters 11 and 12) is the lowest of the five regions in all scenarios despite ambitious EU targets. However, a significant potential is demonstrated in the Behaviour-focused scenario by the emergence of prosumerism, facilitated through small-scale electricity generation (Chapter 10). When introducing new technologies, consider energy costs to avoid worsening energy poverty (Chapters 11 and 12) and adopt measures if needed, such as support for vulnerable groups. Adoption of circular economy principles presents another area with social impact.

20.6.4.2 Environmental impacts

The technology-focused transformation's reliance on CCS technology is indispensable for managing fossil fuel use emissions (**Figure 20.17**). Implementing CCS would help curb emissions while renewable energy capacity is scaled up. However, this technology alone cannot solve issues related to biodiversity loss and land degradation.

Figure 20.19: Effects of alternative pathways and reference scenarios

YuriArcursPeopleimages/Envato

The behaviour-focused pathway's emphasis on transforming agriculture through sustainable practices is critical for addressing soil degradation and enhancing biodiversity. The adoption of precision farming, regenerative agriculture, organic farming and sustainable forestry can restore soil health and reduce chemical inputs, promoting a healthier ecosystem. However, a blanket application of these practices is not feasible across the entire region due to varying local conditions.

Moreover, enhancing the network of protected areas is a crucial component. Although the region has a relatively large number of protected areas, they often lack effective management and connectivity (Chapter 8). By improving their management and interconnectivity, the region can ensure more effective conservation outcomes.

20.6.5 Reflections

For the 21 EU member-candidate-partnership countries within the EE region, utilizing the tools provided by the EU, such as the European Union's Green Deal, is crucial for implementing systematic changes across various sectors while respecting regional specifics, if supported by substantial financial and policy resources. Continuation of dialogue with partner countries and resumption of communication is necessary with the remaining two states – Russia and Belarus – after the end of the war in Ukraine. Given the interconnected nature of modern economies, a coordinated approach to implementing these changes is essential. Uncoordinated changes could lead to unintended socioeconomic impacts, such as temporary increases in food prices due to the agricultural sector's transformation (Chapter 17, **Figure 20.16**, **Figure 20.17**). However, in the long term, these costs are expected to stabilize as the benefits of sustainable practices become evident, particularly in terms of cost savings from avoiding the current pathway (**Figure 20.19**).

20.6.5.1 Synergies and trade-offs

Achieving synergies between various sectors and policies will be key. The transformation of the agricultural sector will result in long-term benefits, such as reduced environmental degradation, improved soil health, and increased biodiversity. This will also have a positive impact on water withdrawal and help in mitigating the adverse effects of climate change (**Figure 20.19**).

The synergies between pathways help reinforce sustainable transformation as, together, they yield co-benefits for human well-being to promote long-term

sustainability and maximize the effects of sustainable solutions across all five systems.

The trade-offs between t pathways involve balancing initial investments in renewable energy supply, circular business models and digital agriculture with the long-term benefits for sustainability and resource efficiency, alongside the adoption of behavioural changes.

20.6.6 Policy implications

The successful implementation of these transformations requires strong political support and well-targeted investments (Chapter 14). The role of public awareness and education is also paramount, as integrating green principles into educational systems from the earliest levels to university can foster a culture of sustainability and environmental stewardship.

Policy measures should be tailored to respect the diverse natural, socioeconomic, and cultural conditions across the region. Local and individual solutions must be prioritized, as a one-size-fits-all approach is unlikely to succeed in a region as diverse as EE.

Economic and political tools will be the most effective instruments for driving these changes. Economic policies must consider vulnerable populations, ensuring that the benefits of these transformations are equitably distributed. Incentives for green investments should prioritize projects that provide opportunities for marginalized communities or regions. Both transformation pathways emphasize the critical role of green finance, but from complementary perspectives.

The technology-focused pathway (20.7.2.5) highlights financial incentives to accelerate the deployment of renewable energies, precision agriculture, and other green technologies. The behaviour-focused pathway (20.7.3.5) underscores financial inclusion and the creation of accessible green investment opportunities for households, communities, and small enterprises. Together, these approaches enable socially equitable and environmentally sustainable economic growth, while promoting inclusive green finance and directly addressing the GEO-7 Policy Questions (PQs) assigned to Chapter 20.

In addition, private sector participation should be actively encouraged through targeted incentives and public-private partnerships, including innovative instruments such as green bonds, debt-for-nature swaps, and blended finance mechanisms that expand investment flows into climate adaptation and resilience projects.

Green Investment and Technology Adoption – Policy Highlights

- Technology-focused pathway (20.7.2.5): stresses financial incentives for scaling renewable energy, precision agriculture, and other green technologies
- Behaviour-focused pathway (20.7.3.5): prioritizes financial inclusion and accessible green investments for households, communities, and small and medium-sized enterprises
- Shared outcome: supports socially equitable, sustainable economic growth and advances inclusive green finance, in line with Chapter 20 PQs
- Private sector engagement: should be expanded through incentives and public-private partnerships
- Innovative financing instruments: green bonds, debt-for-nature swaps, and blended finance can mobilize large-scale investment into climate adaptation and resilience projects

Enhanced Circular Economy: Technology-focused pathway's advances in recycling and circular material use rates (20.2.3) are complemented by the behaviour-focused pathway's interventions reducing consumption and waste generation (20.3.3), maximizing resource efficiency, minimizing environmental impacts, and promoting sustainable consumption habits, answering PQ2 and PQ3.1

Building Socioeconomic Resilience: Both pathways highlight sustainable agricultural practices, focusing on productivity and efficiency (20.2.2 and, respectively emphasizing local, small-scale agriculture and sustainable consumption (20.3.2). This synergy helps enhance food security, local employment, and rural livelihoods while protecting ecosystem services, thus answering PQ3.

Balancing Investments and Behaviour Change: Large-scale technology investments in renewable energy,

infrastructure, and agriculture, could result in social inequities if not balanced with behavioural inclusive approaches, and eliminating energy poverty leading to a balanced approach that answers PQ3, PQ3.1, PQ3.2

Agricultural Land Use and Biodiversity: Technology-focused pathway's increased agricultural production to meet food and energy crop demand (20.2.2) may conflict with behaviour-focused pathway's focus on ecosystem conservation (20.3.4). Policy integration is required thus answering PQ2 and PQ3.1.

Decarbonization Costs and Economic Impacts: The transition to low-carbon energy and adoption of new technologies entail high initial costs, which vulnerable communities could not afford. The behavioural changes' help distribute these costs more evenly, thus answering PQ3.2 (20.7.2.7; 20.7.3.7).

Policy Harmonization: **Table 20.6** below illustrates the types of policies that need harmonization.

20.6.6.1 Enhancing synergies and reducing unintended consequences

Regional Cooperation:

Regional cooperation is essential for realizing the full potential of these changes. For instance, EE has the potential to produce agricultural commodities and

Table 20.6: Levers and policy recommendations for Eastern Europe

	(Technology-focused)		(Behaviour-focused)	
Systems	**Type of lever**	**Levers/actions**	**Type of lever**	**Levers/actions**
Economy and Finances (ch14)	Economic and financial	Improve access to financial capital and investment	Innovation and diverse knowledge system	Focus on indigenous systems and local knowledge for resilience
	Science, tech, innovation	Research into sustainable food system and methods for transformation	Social and cultural	Provide social behaviour change communication strategies to influence social norms and behaviors
	Capabilities	Strengthen farmer knowledge and agricultural extension to improve agronomic techniques for greater productivity and sustainability	Economic and Financial	Improve access to financial capital and investment
Circularity (ch15)	Economic and financial	De-risk finance for circular business models	Economic and Financial	Change market and pricing signals for used products and secondary materials
	Science, tech, innovation	Research into new materials and novel industrial processes for circularity	Social and cultural	Promote traditional and new societal practices for reuse, sharing and repair
	Science, tech, innovation	Digital innovations for supply chains traceability and transparency	Capabilities	Increase awareness of consumers to make circular lifestyle choices

Systems	(Technology-focused) Type of lever	Levers/actions	(Behaviour-focused) Type of lever	Levers/actions
Energy (ch16)	Governance	Develop long-term mitigation pathways with accountability and transparency	Individual and collective action	Raise awareness of the benefits of lower energy lifestyles
	Science and technology	Scale up adoption of different technologies	Economic and Financial	Finance for expansion of facilities
		Increased investment in energy R&D	Individual and collective action	Enable availability of sustainable mobility choices
Food (ch17)	Science, technology and innovation	Advancing technology and genetics for increased yield, nutritional quality, resilience and climate adaptation/ mitigation	Economic and Financial	Change food industry practices to encourage sustainable consumer behaviours
	Institutional and political	Joined-up and strengthened food system governance	Individual and collective action	Change in social norms and collective actions
	Capabilities	Enhanced knowledge sharing of agricultural and food technologies and genetic materials	Skills and capabilities building	Increase public awareness and knowledge of food health and actions
Environment (ch18)	Economic and financial	Equitable access to finance	Social and cultural	Multiple partnerships for behavioural change and action
	Institutional and political	Localise national and international policies	Economic and Financial	Local economic opportunities for protection of nature
	Science, tech, innovation	Biotechnology for ecosystem improvement	Capabilities	Improved science literacy of wider society

food products exceeding regional demand, providing opportunities for export to other parts of the world. Conversely, the region's challenges in transitioning its energy system could be alleviated by collaborating with other regions to gain access to more renewable energy resources and technologies.

Conversely, the region's challenges in transitioning its energy system could be alleviated by collaborating with other regions to gain access to more renewable energy resources and technologies through sharing best practices, support policy alignment, and enhance transboundary sustainability efforts thus answering PQ3.

Public Engagement and Awareness Building:

Public engagement and awareness-raising campaigns drive social acceptance and demand for both pathways' options, fostering adoption of sustainable lifestyles.

Credit: anatoliy_gleb/Envato

The education, information and communication aided behaviour change is crucial for achieving SDG12, while application of modern technologies can achieve SDG1 and 2. ILK based innovations can achieve adaptation and mainstreaming of global environmental crisis in national policies and plans for SDGs 13, 14 and 15 thereby answering policy questions PQ2 and PQ3. Appendix 20.1 lists EE's key trends, conclusions and strategic recommendations across 2030-2040-2050.

20.6.7 Conclusion

By addressing regional priorities holistically, these pathways maximize synergies, enhance resilience, and minimize trade-offs, fostering equitable and sustainable futures.

The region continues to be shaped by two distinct influences: EU-driven policies and the different policies and legal framework followed by Russia and Belarus. As a result, changes are expected to occur at different speeds and scales, but aligning and coordinating these policies with global goals and targets will be paramount for the future. Tailored policy recommendations, sensitive to each country's specific context, are essential for achieving long-term resilience and balancing economic development with climate adaptation, social justice and environmental integrity.

20.7 Latin America and the Caribbean Region

20.7.1 Introduction

The Latin America and Caribbean (LAC) region supports approximately 60 per cent of the Earth's terrestrial species, over 30 per cent of its freshwater resources, and stores an estimated 100–120 billion metric tons of carbon. Yet, despite its rich biodiversity and natural resource endowment, the region faces unprecedented sustainability challenges from the intricate and interconnected effects of the global environmental crises. Consequently, regional priority issues such as changes in land cover dynamics, changes in freshwater quality and availability, and degradation of coastal and marine resources require urgent attention. These priorities are closely linked to multiple systems, including food production, energy generation, waste management, socioeconomic development, and the environment. The Technology-focused Transformation Scenario pathways and Behaviour-focused Transformation Scenario pathways illustrate transformation of these systems across LAC by 2050.

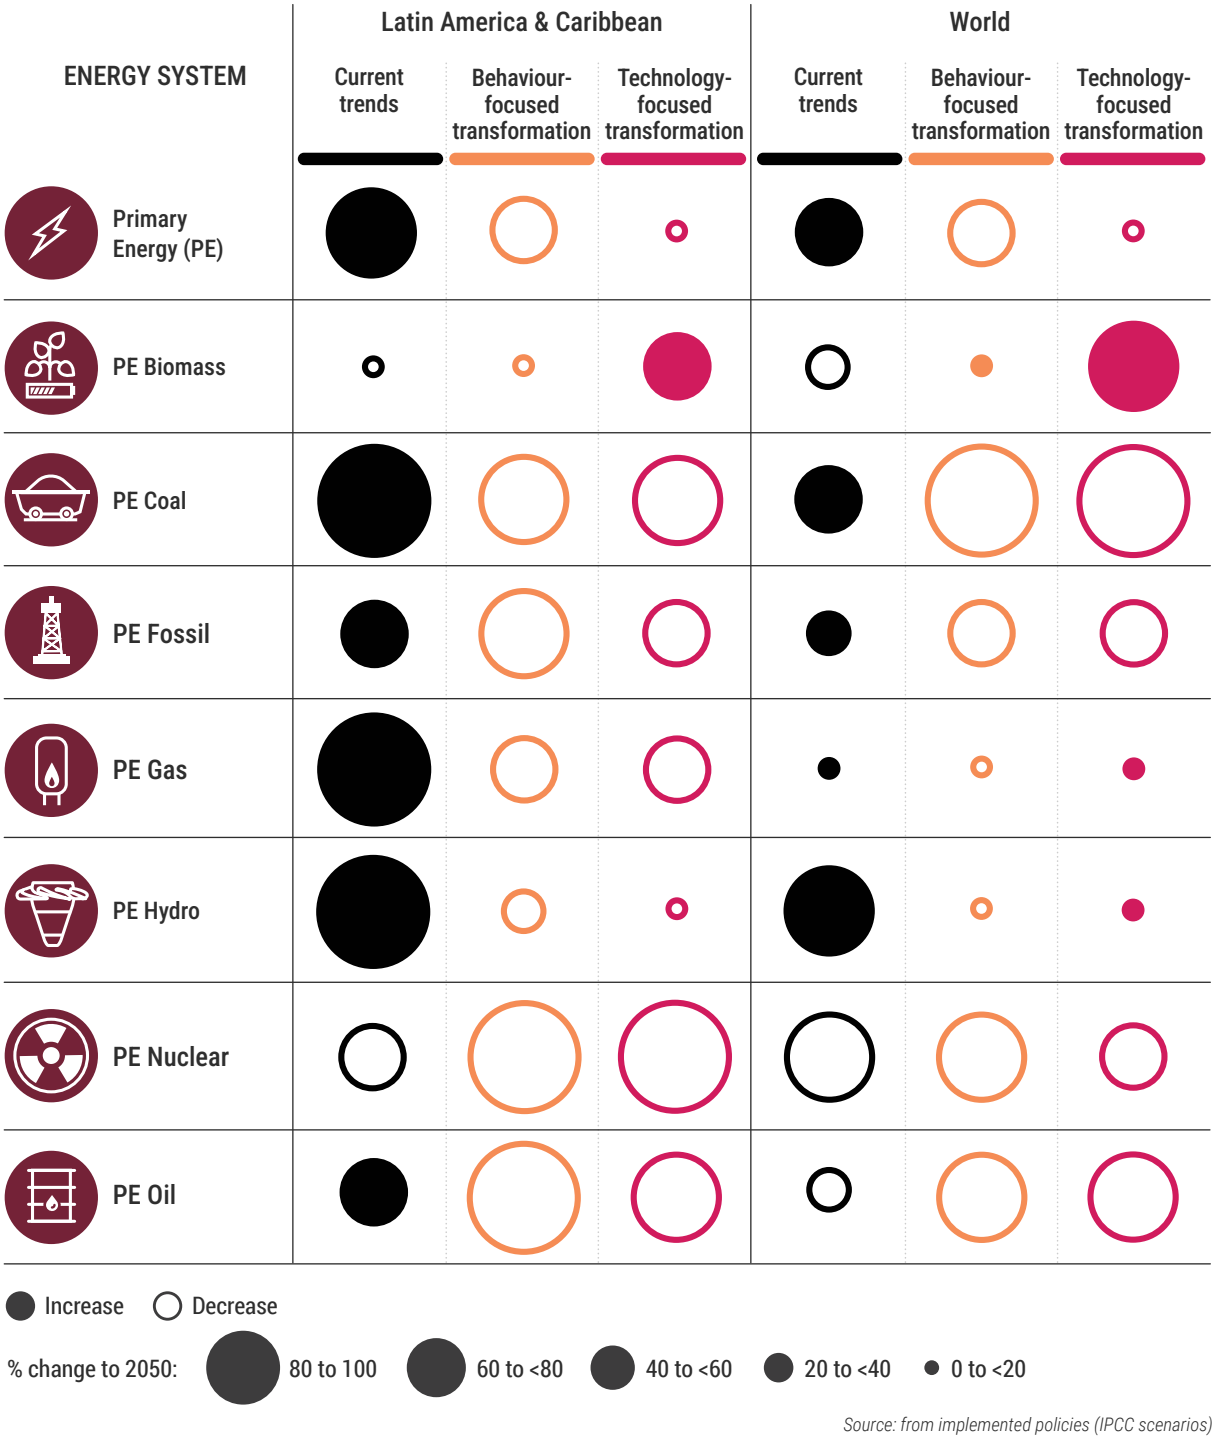
The technology-focused pathway is projected to expand production and improve food availability but at

the cost of increased emissions, water withdrawals, and land-use pressure. In contrast, the behaviour-focused pathway reduces agricultural and livestock footprints while maintaining calorie availability through dietary shifts and agroecological practices. Caloric availability increases while the number of undernourished people falls significantly across LAC. Both transformation scenario pathways show a major shift away from fossil fuels by 2050, with different trajectories across LAC. The technology-focused pathway projects significant reductions in coal and oil use through carbon capture and large-scale electrification, while the behaviour-focused pathway decentralizes energy systems and expands renewables.

Across LAC, environmental systems are under pressure but can deliver major co-benefits through integrated land-use policies. The behaviour-focused pathway projects greater biodiversity recovery, forest expansion, and reductions in methane and nitrous oxide emissions, higher than global averages. The technology-focused pathway shows improvements in air quality and carbon stocks but estimates increased water demand and low biodiversity gain. Coastal and freshwater ecosystems – especially vulnerable in the Caribbean and Central America – would require nature-based solutions, adaptive governance, and stronger restoration finance. In terms of material use and waste generation, the technology-focused pathway's gains in recycling by 2050 are offset by continued extraction and rising e-waste, while the behaviour-focused pathway shows throughput reduction, improved recycling, and enhances water quality. Both pathways improve recycling rates, but only the behaviour-focused pathway reduces overall material throughput and waste generation across LAC. Economic and financial systems require reoriented to support inclusive, low-carbon development across LAC. Both pathways avoid significant climate damage by 2050, but the behaviour-focused pathway does so with lower policy costs and greater equity.

20.7.2 Technology-focused Transformation Pathway

20.7.2.1 Transition to renewable energy



The LAC region is a significant player in the global sustainable energy landscape, particularly in biofuels, hydropower, and emerging renewable energy capacities (Lino and Sáez 2023; Kariuki 2024; Icaza-Alvarez et al. 2024), critical in achieving the project 2050 targets. In the Caribbean, carbon neutrality can be achieved by 2050 primarily through solar PV, wind, battery storage, and strategic importation of e-fuels, with integrated planning across electricity, transport, and cooking sectors to ensure cost-effective decarbonization (Oyewo et al. 2024). The technology-focused pathway projects substantial declines in fossil fuel use, rapid growth in non-biomass renewables, and sector-wide electrification. However, realizing these gains will require integrated strategies to address land-use trade-offs, infrastructure constraints, water resource pressures (Palacios et al. 2024), and socioeconomic disruptions (Allub et al. 2024). **Figure 20.20** shows technology-focused pathway projections for key energy systems indicators.

Fossil fuel dependency is projected to decline sharply by 2050, but land-use trade-offs from renewable expansion require carefully managed (Icaza 2024; Gálvez 2025). By 2050, coal use in the region is projected to decline by 87 per cent, oil by 43 per cent, and total fossil fuel demand by 60 per cent, which put the region in line with global decarbonization targets (UNEP 2021; Lino and Sáez 2023). While the accelerated path to decarbonization by 2050 involves higher initial costs, estimated at 3-12 per cent more than a gradual transition (Oyewo et al. 2024; Kalra et al. 2024), the long-term benefits of a carbon-neutral energy system are significant.

Non-biomass renewables – including solar, wind, and hydro – are projected to increase by 56 per cent, which exceeds the global estimate of 45 per cent (Camargo-Bertel et al. 2024). Coal and oil trade are projected to decrease by 92 per cent and 54 per cent, respectively; however, this transition may displace workers in fossil fuel-dependent subregions (Rodríguez-Arce et al. 2024). Reductions in fossil fuel extraction and combustion could also lower risks of marine oil pollution and terrestrial ecosystem degradation, provided they are accompanied by strong environmental safeguards and integrated spatial planning to prevent biodiversity loss and adverse social impacts (Hampl 2024; Icaza 2024; Gálvez 2025).

Electrification and distributed energy systems are projected to expand substantially across LAC, yet universal access and grid resilience remain persistent challenges (Camargo-Bertel 2024). Regional electricity demand is also expected to increase by approximately 52 per cent by 2050, relative to a global average increase

Figure 20.20: Current Trends, Technology-focused and Behaviour-focused Scenario pathway projections for key energy systems indicators

Source: from implemented policies (IPCC scenarios)

of 44 per cent (IEA 2023). This demand growth is anticipated to be driven primarily by the electrification of transport, industry, and buildings (Allub et al. 2024; Icaza 2024). Large-scale investments in renewable generation, distributed resources, smart grids, and storage systems are required to achieve these targets while ensuring reliability and equitable access (Gálvez 2025).

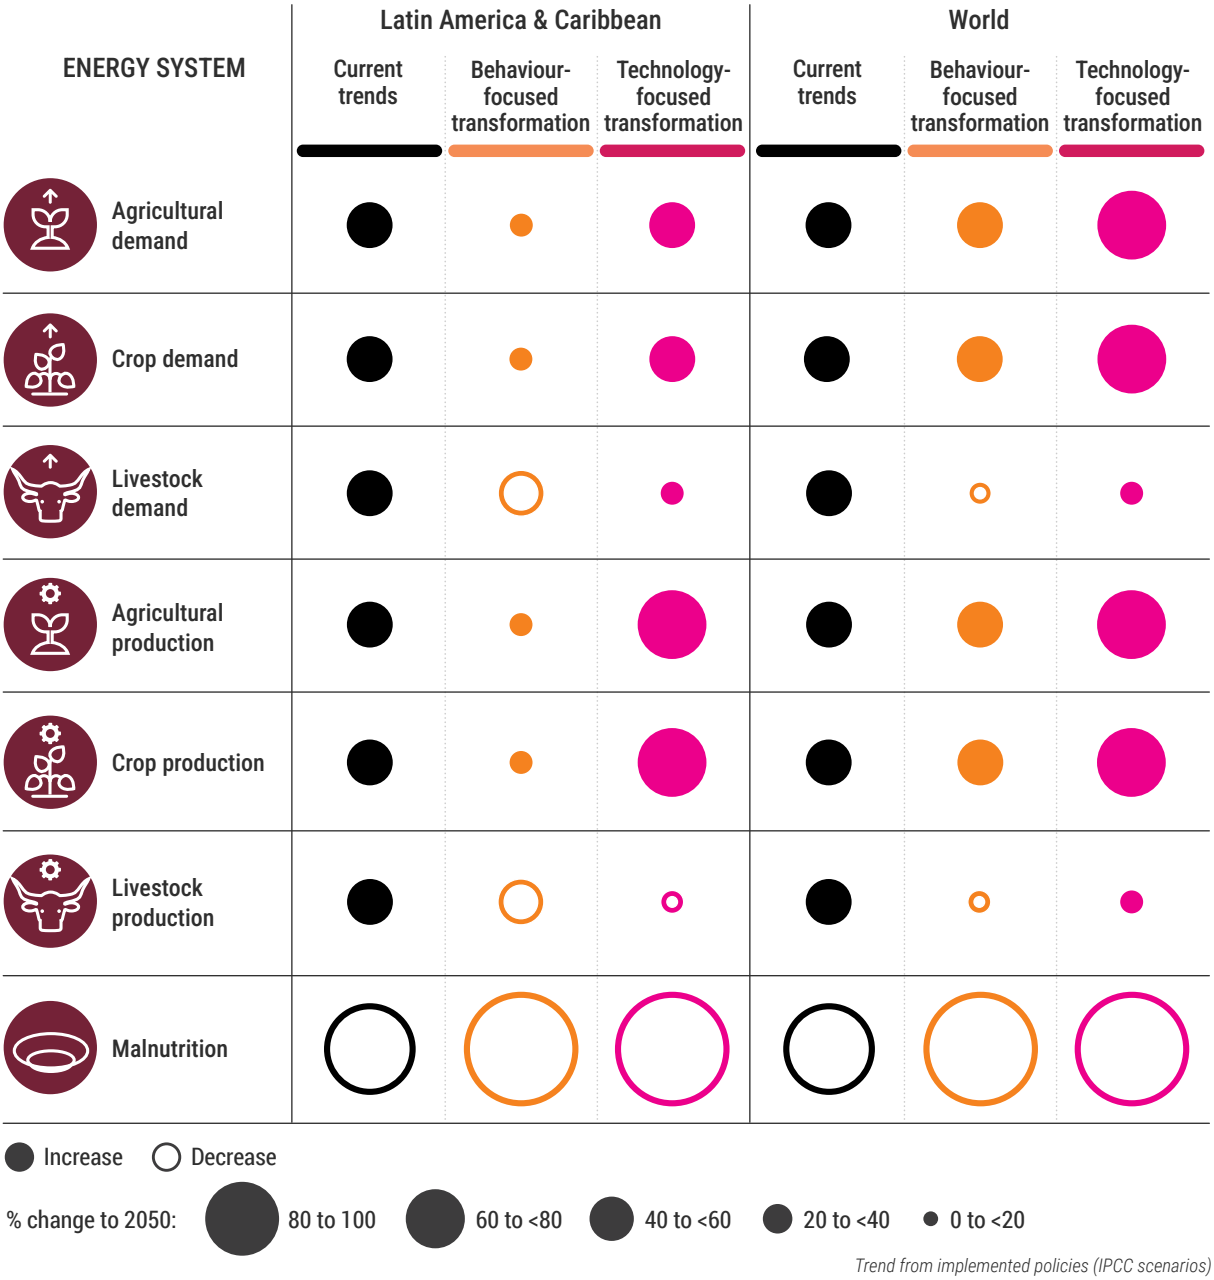
Final energy demand in LAC is projected to increase by approximately 15 per cent by 2050, which reflects notable gains in energy efficiency relative to economic and population growth (Camargo-Bertel et al. 2024). Industrial demand is projected to increase by 12 per cent, while residential and commercial demand could increase by approximately 20 per cent, supported by efficiency improvements and behavioural shifts

towards energy sufficiency (Camargo-Bertel et al. 2024; Gálvez 2025). In contrast, transport energy demand is projected to decrease by 11 per cent, primarily from the electrification of mobility systems and modal shifts in urban subregions (Yépez-García 2024; Icaza 2024).

Achieving a 100 per cent renewable energy mix by 2050 requires regional cooperation among LAC countries to effectively leverage collective resources and sustainability advantages (Icaza et al. 2024). One promising option is the deployment of offshore floating photovoltaic systems, which can help overcome land constraints while enabling effective use of the Caribbean's extensive marine areas for power generation (Breyer et al. 2023; Oyewo et al. 2024). This approach could also reduce fuel imports by approximately 70 per cent by 2050 relative to current levels, which reduces dependence on fossil fuels and strengthen energy security (Oyewo et al. 2024). {16.2-16.4}.

20.7.2.2 Sustainable agriculture and food system

The technology-focused pathway projects significant agricultural productivity gains in LAC by 2050, with increased food availability and limited cropland expansion through sustainable intensification. However, uneven reductions in malnutrition and modest improvements in calorie inequality highlight the need for stronger policy measures to ensure equitable food access and nutritional outcomes across the three subregions (FAO et al. 2024; Díaz-Bonilla & Piñeiro 2024). Regional agricultural demand is projected to increase by 22 per cent by 2050 – below the global increase of 37 per cent – driven by a 21 per cent increase in crop demand and a 25 per cent increase in livestock consumption. Livestock production is projected to increase by 50 per cent, which significantly exceeds the global average of 10 per cent, while effecting a 40 per cent increase in methane emissions (Caron et al. 2018; Wang et al. 2021; World Bank 2024). Malnutrition is projected to decrease by 75 per cent, however, this falls short of the global estimate of near eradication, at 98 per cent, by 2050. Calorie inequality is projected to decrease by 12 per cent – well below the 54 per cent global average – which underscores the persistent disparities in food access (**Figure 20.21**) (FAO et al. 2024; Sandoval 2024).



While intensification under a technology-focused pathway can increase land-use efficiency and limit cropland expansion in LAC, it could risk increasing freshwater stress and nutrient run-off, which undermines the long-term sustainability of agriculture and ecosystem health (Lentini 2022). By 2050, cropland expansion is projected to remain constrained at 12 per cent; however, agricultural water demand is expected to increase by 9 per cent, relative to a 12 per cent global decline. This pressure on freshwater resources can be compounded by higher fertilizer application, which is projected to increase by 17 per cent to sustain crop production demand. Such intensification is likely to exacerbate nitrogen and phosphorus run-off, with serious implications for both freshwater and marine ecosystems (Jaax et al. 2024). {17.2.1 to 17.2.5}.

20.7.2.3 Circular economy and pollution control and prevention

By 2050, circularity in LAC shows modest improvements in material efficiency and recycling, which are offset by persistently high material footprints, increased resource demand, and inadequate waste management under the technology-focused pathway. While total material demand in the region is projected to decline by five per cent – compared to a two per cent global increase – this reflects only limited improvements in material efficiency. The per capita material footprint is expected to reach 14–25 tons, exceeding the recommended sustainability threshold of 6–8 tons (UNEP 2021). At the same time, landfill waste is projected to increase by nine per cent and e-waste by 15 per cent, primarily from growing consumption and insufficient waste infrastructure (Gallego-Schmid et al. 2024).

The technology-focused pathway projects improvements in nutrient management and recycling in LAC but lags behind global progress, as increased industrial water use and material extraction continue to strain freshwater systems and aquatic ecosystem health. Nitrogen and phosphorus balances are projected to decline by 19 per cent and 25 per cent, respectively, yet nitrogen use efficiency is expected to fall by 15 per cent compared to a 21 per cent global improvement. Freshwater concentrations of nitrogen and phosphorus are projected to decrease by 12 per cent and 23 per cent, respectively, relative to global reductions of 25 per cent and 27 per cent. Industrial water use in the region is projected to increase by 15 per cent by 2050, compared to a global decline of approximately 10 per cent per year, shaped by growth in the energy, manufacturing, and resource extraction sectors. Extraction of industrial sand,

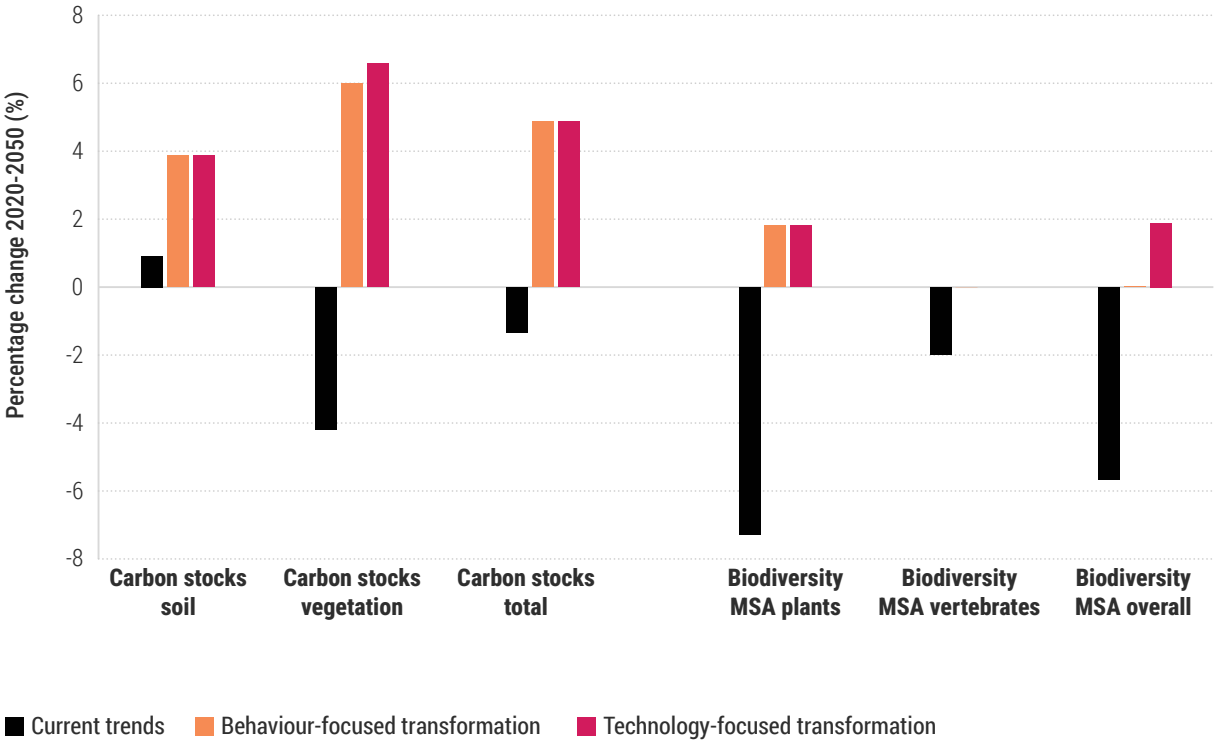
Figure 20.21: Current Trends, Technology-focused and Behaviour-focused Scenario pathway projections for key food systems indicators

gravel, and biomass also is projected to intensify, with wild catch rising by 36 million metric tons per year. These pressures threaten water availability and aquatic ecosystems across the regions (Jaax et al. 2024) {15.3}.

20.7.2.4 Economic and financial systems reforms

Targeted economic and financial reforms – centred on resilient infrastructure investment, fiscal realignment, and green finance – are essential for LAC to avoid climate damages equivalent to 100 per cent of GDP by 2050. These reforms are also critical to securing a more inclusive, climate-resilient future, despite disproportionately high policy costs. The region is highly exposed to climate-related economic shocks, with potential losses of 83 per cent of GDP by 2050, well above the global average (Salazar et al. 2024). Under the technology-focused pathway, LAC could avoid climate damages equivalent to its entire GDP or US$2.5 trillion by 2050, aligning with global estimates. Achieving this, however, requires scaling investments in climate-resilient infrastructure – including water, sanitation, and energy – at levels estimated between 7 and 19 per cent of GDP annually by 2030 (Yarlagadda

et al. 2023). Without such investments, climate-related GDP losses could reach US$232 trillion, or 83 per cent of regional GDP, far exceeding the global average of 129 per cent (ECLAC 2023). Although policy costs are steep – projected at 200 per cent of GDP by 2050, double the global average under the technology-focused pathway – expanding green finance and carbon pricing mechanisms can help unlock sustainable growth. {14.3-14.6}



20.7.2.5 Conservation and restoration of nature

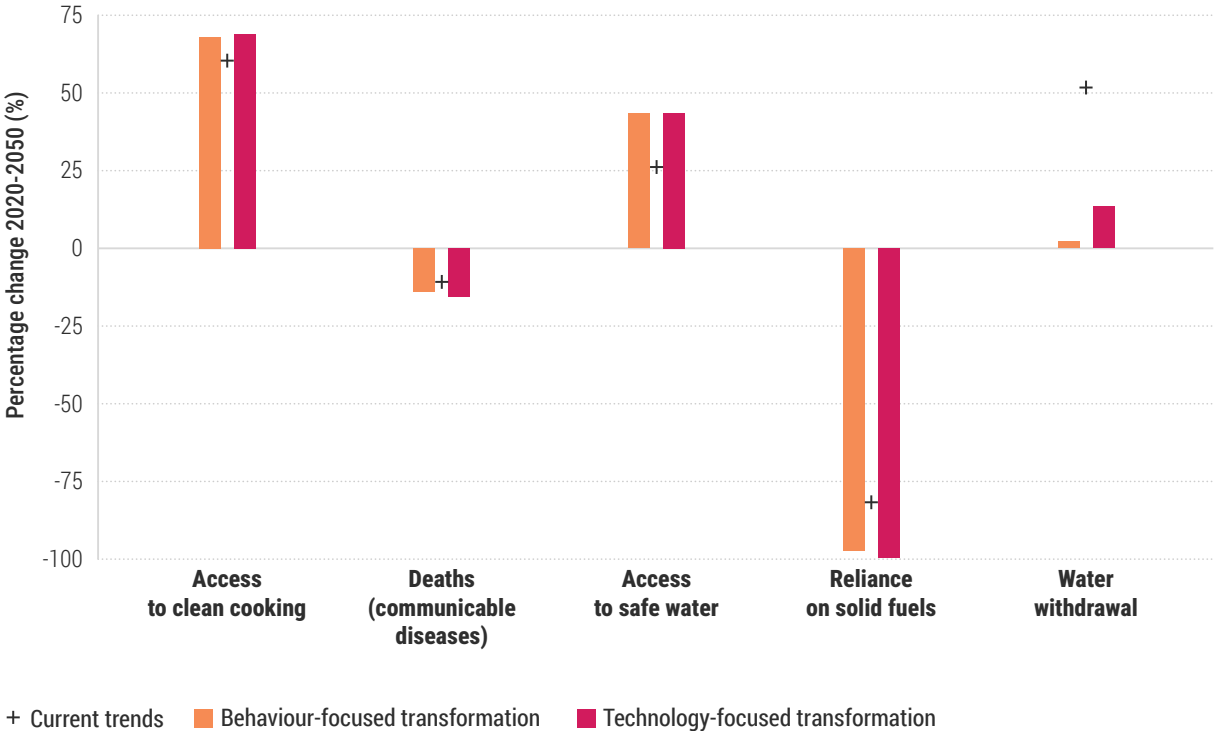
The technology-focused pathway projects that conservation and restoration of nature in LAC by 2050 is achievable, but only through coordinated, cross-sectoral action {18.2.1; 18.2.2; 18.2.4}. For example, air quality is projected to improve substantially, with nitrogen oxides emissions declining by around 50 per cent, leading to significant public health benefits, particularly in urban areas (Vélez-Henao 2025). Similarly, freshwater quality is also projected to improve by 14 per cent, due to improved land-use practices and reductions in pollutants. However, these gains contrast with the continued vulnerability of ocean ecosystems, where acidification and warming are projected to persist, posing severe risks to marine biodiversity and coastal livelihoods, especially in the Caribbean. **Figure 20.22** illustrates the projected changes in biodiversity and carbon stocks across LAC by 2050 under the technology-focused pathway.

The technology-focused pathway projects measurable gains in forest stability, carbon sequestration, and modest biodiversity recovery in LAC, outperforming global trends. By 2050, forest cover in the region is projected to remain stable at + one per cent, with targeted reforestation leading to significant carbon sequestration. Total carbon stocks are projected to increase by approximately five gigatons of carbon (GtC), including about seven GtC stored in vegetation and four GtC in soils, both above global averages (Cerri et al. 2024). Biodiversity outcomes are more modest: mean species abundance is projected to increase by around one per cent, with plants improving by roughly two per cent, while vertebrate biodiversity remains unchanged. Even so, these trends contrast with global averages, which show declines across all biodiversity indicators.

The technology-focused pathway also projects a 63 per cent reduction in CO_2 emissions, due largely to the adoption of carbon capture technologies. The scenario also estimates a 29 per cent increase in forest and natural land cover, supporting biodiversity conservation and ecosystem resilience, alongside a

Figure 20.22: Projected changes to carbon stocks and biodiversity from 2020 to 2050

16 per cent rise in water withdrawals linked to growing industrial and agricultural demands (Rodríguez et al. 2022). Carbon capture and storage (CCS) capacity is projected to expand to 271 million metric tons of carbon dioxide per year, which contributes to net-zero targets. However, achieving this outcome requires robust groundwater monitoring, strict siting controls, and strong environmental oversight to prevent unintended harms (Palacios et al. 2024).



20.7.2.6 Implications of the Technology-focused Pathway

20.7.2.6.1 Socioeconomic system

Despite technological advances that increase productivity, reduce emissions, expand energy access, improve air quality, and increase carbon storage in LAC, the socioeconomic system remains at risk. Unequal electrification, ecosystem degradation, and unsustainable fiscal burdens continue to threaten the well-being and livelihoods of millions who depend on natural resources and public services for survival. These vulnerabilities are compounded by persistent inequalities, high informality, and fiscal constraints. Under the technology-focused pathway, malnutrition is projected to decrease by 75 per cent and agricultural demand to increase by 22 per cent by 2050. However, reductions in calorie inequality are limited to 12 per cent – relative to the global average of 54 per cent – which underscores the persistent marginalization of rural and low-income populations. **Figure 20.23** presents the projected changes in key socioeconomic indicators for LAC and the world by 2050.

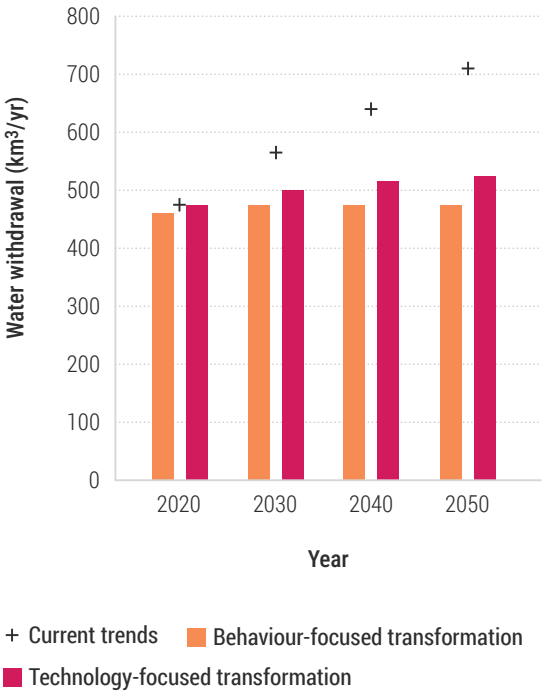
In the energy sector, electrification and decentralized systems risk deepening energy poverty unless accompanied by inclusive finance and institutional reform. Electricity demand in LAC is projected to increase by 52 per cent by 2050 – exceeding the global increase of 44 per cent – yet 17 million people, mainly in rural Central America and the Caribbean, still lack reliable access. Under the technology-focused pathway, nitrogen oxides emissions are projected to decrease by about 50 per cent, forest cover to stabilize at about one per cent, and carbon stocks to increase by approximately five GtC. Despite these gains, ecosystem services remain highly vulnerable: biodiversity shows only modest improvements, vertebrate biodiversity stagnates, and ocean acidification persists. These pressures threaten the well-being of 140 million people who rely on ecosystem services for water, food,

Figure 20.23: Projected changes in key socio-economic indicators for LAC and the World from 2020 to 2050

and livelihoods, particularly in coastal and forested regions (Hernández-Blanco et al. 2020). Although the technology-focused pathway avoids climate damages, policy costs are projected to reach 200 per cent of GDP – twice the global average – amid rising debt and constrained fiscal space (Eguino et al. 2024).

20.7.2.6.2 Environmental systems

The accelerated transition under the technology-focused pathway provides limited environmental benefits while intensifying ecosystem stress across LAC, as increasing livestock production, nutrient run-off, and freshwater withdrawals undermine biodiversity, water quality, and land resilience. Livestock production is projected to increase by 50 per cent, resulting in a 40 per cent increase in methane emissions and putting substantial pressure on water and land systems (Seijger et al. 2024). In South America's forested areas, grazing expansion threatens biodiversity-rich transitional ecosystems, increasing risks of habitat loss and fragmentation. These impacts are compounded by nutrient run-off – particularly nitrogen – resulting from a 15 per cent decline in efficiency, which further degrades freshwater systems. Although forests are projected to remain stable, this could conceal stagnating biodiversity and increasing vulnerability to climate extremes. Targeted measures such as water efficiency technologies and pollution reduction in subregions with intensive agriculture and high water demand, are required to ensure that the projected 16 per cent increase in freshwater withdrawals (~13 km³/year) does not undermine sustainability goals (**Figure 20.24**).



Environmental outcomes under the technology-focused pathway in LAC reflect modest gains in forest cover and overall biodiversity, however, persistent pressures from waste, nutrient run-off, and stagnating vertebrate recovery underscore the importance of strong land-use, pollution, and ecosystem protection policies to protect freshwater and coastal systems. Overall biodiversity is projected to increase by four per cent, yet vertebrate biodiversity remains stagnant. The expansion of non-biomass renewables by 56 per cent significantly reduces fossil fuel emissions and oil-related marine pollution. However, growing waste and poor nutrient cycling continue to threaten aquatic ecosystems: landfill waste is projected to increase by nine per cent and e-waste by 15 per cent, which intensify risks for coastal and inland waters. Phosphorus and nitrogen concentrations are projected to decrease by 23 per cent and 12 per cent, respectively, however, these reductions remain below global averages (27 per cent and 25 per cent) and are insufficient to prevent eutrophication in estuaries and lagoons (Cindrella & Renjith 2025).

20.7.3 Behaviour-focused Transformation Pathway

20.7.3.1 Transition to renewable energy

The behaviour-focused pathway is characterized by sharp declines in fossil fuel use, increased electrification, expanding community-based systems, and greater reliance on renewables and bioenergy. By 2050, fossil fuel demand in LAC is projected to decrease by 73 per cent – including a 72 per cent drop in coal and a 59 per cent decline in gas – higher than the global reduction of 63 per cent and indicate a structural shift towards energy independence and climate mitigation. Electricity demand is projected to increase by 49 per cent, primarily from electrification across buildings, mobility, and industry. Yet total final energy demand is projected to decrease by 40 per cent – well above the global average decline of 32 per cent – which could be linked to behaviour change, such as increased use

Figure 20.24: Water withdrawal scenarios for LAC and the World

of energy-saving technologies (Vélez-Henao 2025). **Figure 20.25** illustrates the projected energy mix in LAC by 2050 under this pathway.

LAC can achieve inclusive energy access and deep decarbonization by 2050 through a behavioural transition that scales decentralized renewables, doubles wind and solar deployment, and drives a 92 per cent surge in bioenergy – positioning the region as a global leader in sustainable energy transformation. The behaviour-focused pathway promotes decentralized systems, including solar home systems, microhydro, and mini-grids, enabling energy access for over 20 million people currently underserved in rural LAC. Beyond expanding access, these investments also stimulate economic opportunities, with every US$1 million invested in clean energy and energy-efficient buildings across LAC generates an average of 5.5 full-time jobs (Esteves et al. 2024). Biomass energy demand is projected to increase by 92 per cent, surpassing global projections of +65 per cent and positioning LAC as a key bioenergy producer (IRP 2019; Holechek et al. 2022; IEA 2023). The behaviour-focused pathway projects a 100 per cent increase in non-biomass renewable energy, such as wind and solar, which underscores the region's potential to diversify its energy mix and reduce its carbon footprint, with wind turbines and solar photovoltaic estimated to constitute significant shares of the energy mix by 2050 (França et al. 2023; Camargo-Bertel et al. 2024) {16.2.-16.4}.

20.7.3.2 Sustainable agriculture and food system

Transformative shifts in consumption, production, and rural equity can enable LAC to increase food production by 10 per cent while stabilizing demand and reducing livestock-related pressures by 2050. Under the behaviour-focused pathway, food demand stabilizes, and dietary shifts reduce environmental stressors while maintaining production growth. By 2050, agricultural demand in LAC is projected to increase by 0.35 per cent – compared to global estimates of 33 per cent – due to a 25 per cent decline in livestock demand and strong shifts towards healthier diets (Robinson 2024). Despite this, agricultural production grows by 10 per cent, with crop output increasing by 12 per cent while livestock production declines by 27 per cent (**Figure 20.26**).

The behaviour-focused pathway projects a 98 per cent reduction in malnutrition across LAC by 2050, higher than global averages and would effectively eliminate hunger risk in the region. Calorie inequality is expected

Figure 20.25: Share of total energy use by source in LAC from 2020 to 2050

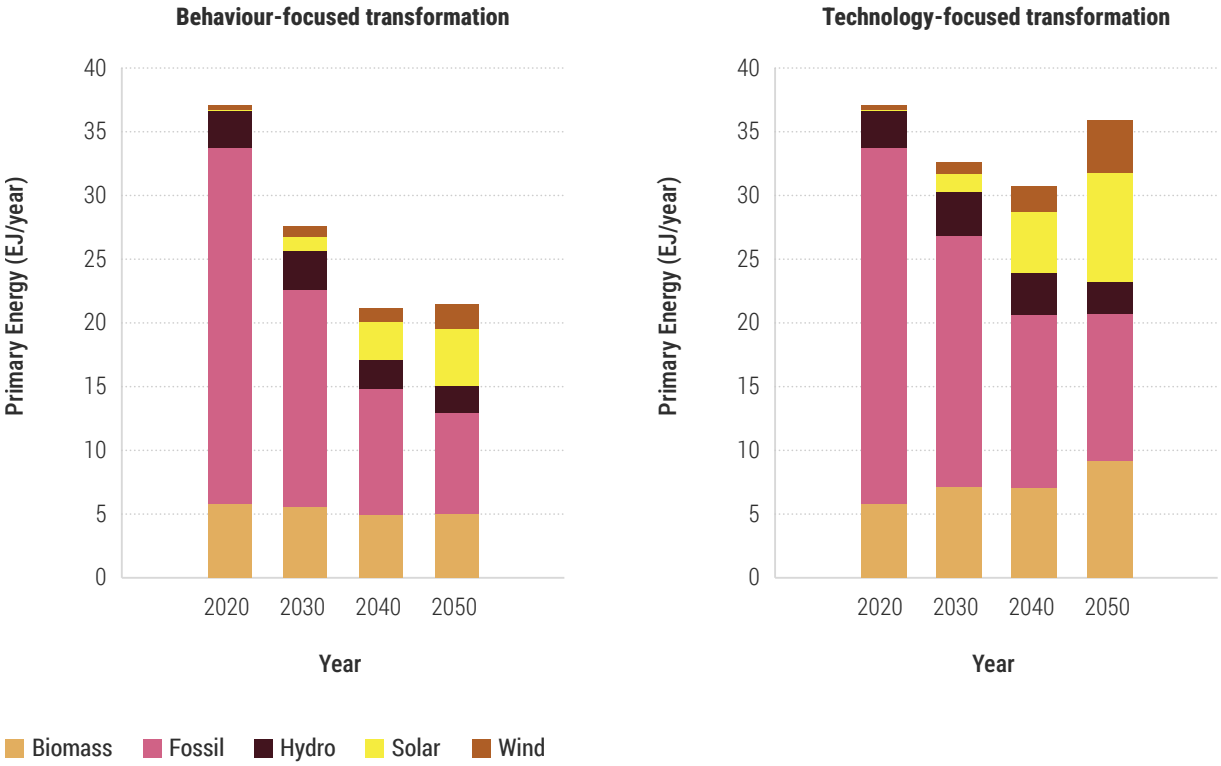


Figure 20.26: Projected trends in agricultural demand and production in LAC from 2020–2050

to improve by 58 per cent, supported by expanded local food production, stronger social safety nets, and reduced food waste. While cropland area is projected to grow by 12 per cent, the pathway also enables the restoration and conversion of 190–296 million hectares to regenerative farming. Agricultural water demand is projected to decrease by 12 per cent and nutrient run-off by 20 per cent by 2050 – a significant improvement given that agriculture currently consumes more than 70 per cent of freshwater and is a major source of pollution in key river basins {17.2.1-17.2.5}.

20.7.3.3 Circular economy and pollution control prevention

By 2050, the behaviour-focused pathway positions LAC to achieve significant circular economy gains, reducing material demand by 10 per cent and waste generation by 19 per cent, comparable to the projected global waste reduction of 20 per cent. However, increased extraction of metals and marine resources threatens to offset these improvements, which underscores the need to align pollution control and resource governance with sustainable consumption and trade. Regional extraction of aluminium is projected to increase by 57 per cent, copper by 86 per cent, and wild catch by more than 92 million tons per year mainly due to export-oriented demand and increased infrastructure requirements.

Despite advances in recycling and water discharge quality, persistent gaps in infrastructure, nutrient management, and the formal recognition of informal waste systems continue to limit the full potential of circular economy and pollution prevention in LAC. Under the behaviour-focused pathway, recycling and reuse increase, however, inadequate collection, processing, and infrastructure remain major barriers (Gallego-Schmid et al. 2024). By 2050, recycling rates in LAC are projected to reach 30 per cent for iron ore and 15 per cent for construction materials; however, many countries in the region will continue to fall below global averages in both capacity and efficiency. Informal recycling systems, particularly in urban areas, continue to play a central role, with waste pickers making substantial contributions yet lacking formal recognition and support (Vélez-Henao 2025). E-waste is projected to increase by 15 per cent without adequate recovery infrastructure. The pathway also reduces industrial water use by 12 per cent and improves water discharge quality by nine km^3/year. Phosphorus concentrations are projected to decrease by three per cent and nitrogen by seven mg N/L, however, these gains remain below global reductions of 25 per cent and 18 mg N/L, respectively.

Moreover, nitrogen use efficiency in croplands are projected to decrease by 17 per cent, relative to a global improvement of nine per cent. {15.3}.

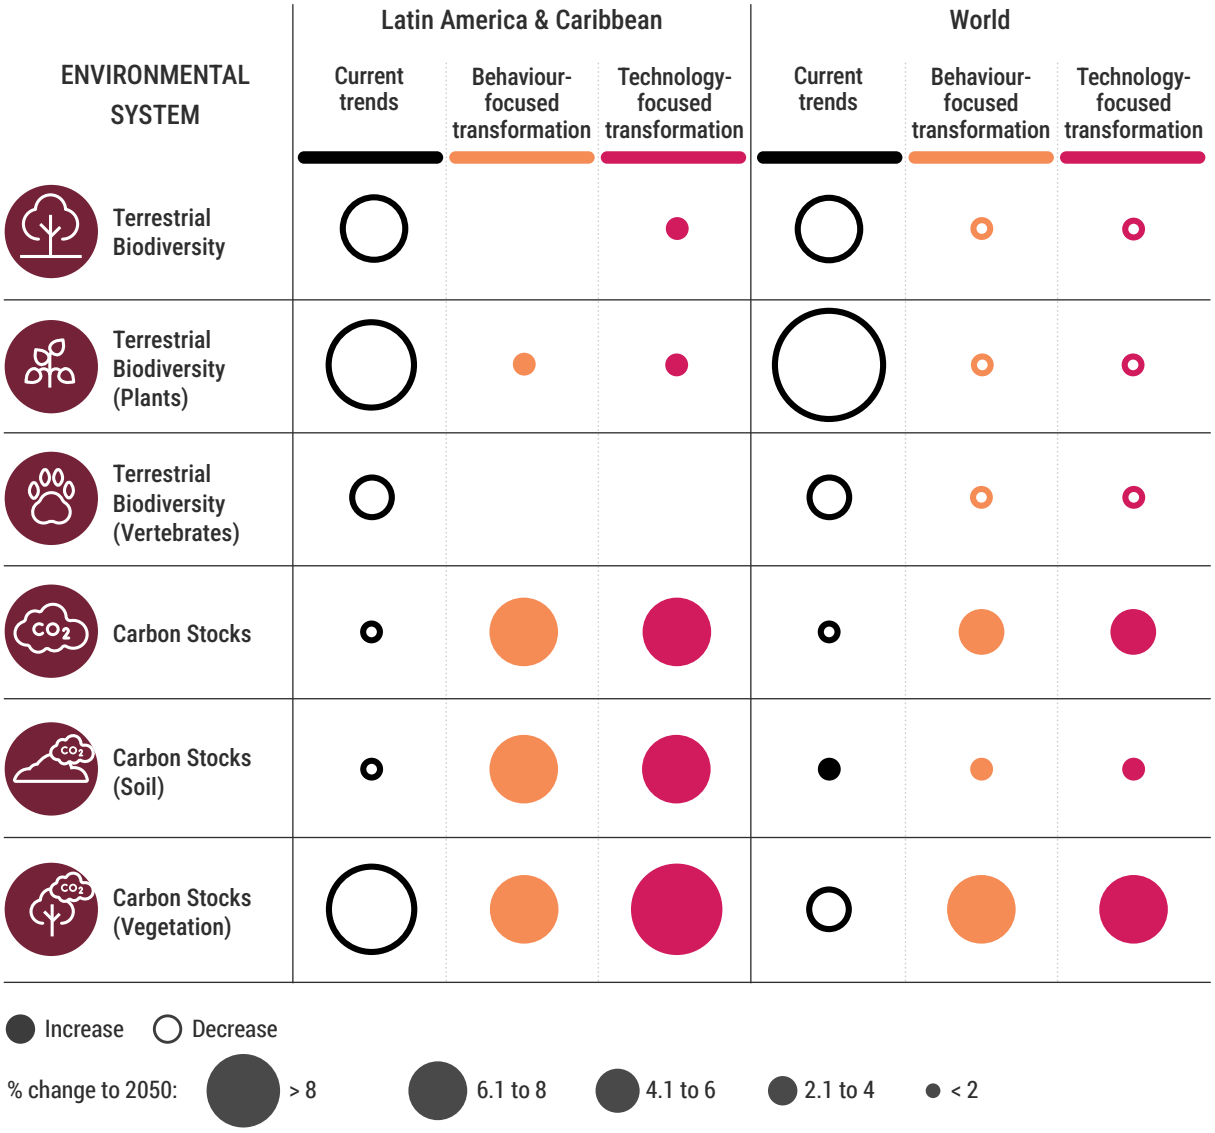
20.7.3.4 Economic and financial systems reforms

By 2050, economic and financial reforms in LAC under the behaviour-focused pathway indicates a rapid transition towards inclusive, low-carbon development. Despite an estimated 2 per cent GDP loss from climate risks, the region is projected to achieve a 60 per cent increase in overall GDP alongside expanded trade, which demonstrates that sustainable finance and institutional strengthening can enable equitable growth while addressing demographic and environmental pressures. Exports and imports are projected to increase by 50 per cent and 45 per cent, respectively, while per capita GDP is projected to increase by 28 per cent. Population growth could reach 14 per cent, with urbanization levels increasing to 87 per cent. Market interventions, combined with strengthened institutional capacity in public agencies, are critical to managing these transitions (Eguino et al. 2024). The behaviour-focused pathway also advances sustainable finance, community-led investment, and inclusive financial practices to accelerate the shift to a low-carbon economy and improve social equity {14.3-14.6}.

20.7.3.5 Transformative conservation and restoration of nature

The behaviour-focused pathway positions LAC as a global leader in conservation and restoration, by achieving net-negative emissions through a 50 per cent reduction in CO_2, a 16 per cent expansion in forest and natural land, and a five GtC increase in carbon stocks – driven by reforestation, regenerative agriculture, and Indigenous-led ecological stewardship {18.2.1; 18.2.2; 18.2.4}. These outcomes exceed global averages and are supported by large-scale reforestation, regenerative agriculture, and afforestation across 190–296 million hectares. Forest and natural land cover is projected to expand by 16 per cent, reversing decades of degradation and fragmentation. This restoration, combined with reduced livestock-driven land conversion, is projected to increase mean species abundance by 1.5 per cent, with stronger gains among plants (+1.8 per cent) than vertebrates (+0.4 per cent) (**Figure 20.27**). Central to this pathway is the empowerment of local communities and Indigenous Peoples, whose knowledge and stewardship underpin sustainable and resilient environmental practices (Gallego-Schmid et al. 2025).

20.7.3.6 Implications of the Behaviour-focused Pathway



20.7.3.6.1 Socioeconomic system

Under the behaviour-focused pathway expansion of forest and natural land cover, improved water security, and renewable energy transitions can protect ecosystem service values while creating new livelihood opportunities and transformative routes to reduce poverty, inequality, and vulnerability across LAC (Batista et al. 2024; Cabieses and Huerta 2024). By 2050, the behaviour-focused pathway projects a 16 per cent increase in forest and natural land cover which could improve biodiversity, reduce wildfire risks, and significantly strengthen the region's climate change adaptation and mitigation capacity. The behaviour-focused pathway model suggests that increased opportunities in renewable energy sectors can have a transformative impact on social structures, contributing to reducing inequality and poverty (Tundys and Bretyn 2023).

Under the behaviour-focused pathway, livestock demand in LAC declines by 25 per cent, while plant-based consumption increases, resulting in a modest 10 per cent increase in total agricultural production. However, smallholder farmers – who produce over 60 per cent of food in LAC – require targeted investments in capacity-building, market access, and agroecological extension services to benefit from this transition (Kraak et al. 2024). Similarly, decentralized renewables expand access and create jobs, however, equity mechanisms are required to ensure inclusion. The behaviour-focused pathway projects a 49 per cent increase in electricity demand and a 155 per cent rise in non-biomass renewables, particularly solar and wind, with decentralized systems expanding across rural and underserved areas.

Forest and natural land cover expand by 16 per cent under the behaviour-focused pathway, which supports carbon sequestration and ecosystem services. These environmental gains support livelihoods in forestry, tourism, and watershed protection. However, for these co-benefits to translate into tangible socioeconomic gains, nature-based solutions must be embedded within local development strategies. The behaviour-

Figure 20.27: Implications of the Current Trends, Behaviour-focused and Technology-focused Scenario pathways for key environmental system indicators

focused pathway projects a 10 per cent decline in material demand and a 19 per cent reduction in waste, accompanied by improved recycling systems and a 30 per cent iron ore recycling rate. Incorporating nature-based solutions and circular economy strategies into local development planning offers LAC the opportunity to achieve more equitable, resilient, and low-carbon growth – but realizing these gains will depend on retraining labour forces and integrating environmental progress with inclusive economic reforms (Kraak et al. 2024).

20.7.3.6.2 Environmental systems

The behaviour-focused pathway shows wide-ranging environmental gains in LAC by 2050 – cutting CO_2 emissions by 50 per cent, reducing agricultural and energy pressures, and restoring ecosystem functions through reforestation, agroecology, and a shift to decentralized, low-impact renewables. Agroecological food systems reduces environmental degradation and restore ecosystem functions. Under the behaviour-focused pathway, agricultural production in LAC increases modestly by 10 per cent while food demand remains stable at 27 per cent. This could enable a 12 per cent reduction in agricultural water use and a 20 per cent decline in nutrient run-off, improving soil and freshwater quality. Decentralized renewables and lower energy demand reduces pollution and protect natural ecosystems. Under the behaviour-focused pathway, final energy demand decreases by 40 per cent, which limits the need for new energy infrastructure

Credit: Edovideo/Envato

and minimize environmental disturbance. Fossil fuel use decreases by 73 per cent, while biomass increases by 92 per cent, thereby displacing more sources of pollutants.

The adoption of circular economy principles under the behaviour-focused pathway directly addresses pollution at its source, particularly in industrial areas, by reducing material demand by 10–15 per cent and scaling up recycling efforts. By 2050, forest and natural land cover in LAC is projected to expand by 16 per cent, which supports an additional five GtC in carbon stocks and higher than global averages. CO_2 emissions decline by 50 per cent and methane by 65 per cent, resulting in improved air quality and easing ecosystem stress. Biodiversity also benefits: mean species abundance increases by 1.5 per cent, while reforestation and ecosystem restoration strengthen biodiversity corridors. Circular material flows reduce land and marine pollution, though nutrient inefficiencies remain a challenge across the region. Material throughput is projected to fall by nine per cent and waste generation by 19 per cent, supported by advances in recycling – including iron ore recycling reaching 30 per cent – and expanded composting initiatives especially in rural and underserved urban areas (Vélez-Henao 2025).

20.7.4 Implications for Regional Priorities

20.7.4.1 Land cover dynamics

By 2050, contrasting pathways in LAC (**Table 20.7**) highlight that behavioural shifts can enable forest regeneration and large-scale carbon sequestration, while technology-focused approaches may only stabilize land cover without reversing ecosystem degradation. Under the behaviour-focused pathway, forest and natural land cover are projected to expand by 16 per cent, which is supported by dietary change. A 25 per cent decline in livestock demand, and agroecological practices are projected to restore up to 296 million hectares to regenerative agriculture and sequester between 12–20 GtC equivalent annually.

Cropland expansion is limited to 12 per cent, with crop production increases estimated at 12 per cent, largely through diversified, low-input mixed farming systems rooted in traditional knowledge (Gallego-Schmid et al. 2025). In contrast, the technology-focused pathway depends on land-sparing intensification: although cropland also expands by 12 per cent, total agricultural production increases by 53 per cent, due to technological innovation. However, livestock production increases by 50 per cent under this pathway, resulting in increased

Table 20.7: Land cover dynamics related results, response options and regional considerations

Result (% change to 2050)	Land Cover Dynamics	Response Option	Levers*	Subregional Considerations/Actions
Agricultural demand grows by 22%. (Technology-focused pathway)	Increased land pressure risks cropland expansion into natural areas.	Promote sustainable intensification and land-sparing technologies.	G, K&I, E&F	• Caribbean: Urban agriculture and coastal zone protection (Galaitsi et al. 2024) • Central America: Precision farming to minimize deforestation (Ivale et al. 2024) • South America: Strict zoning to avoid Amazon conversion (Messias et al. 2024)
Energy crop demand expands 25%. (Technology-focused pathway)	Moderate expansion reduces land competition compared to global trends.	Prioritize multi-use bioenergy landscapes and agroforestry.	K&I, G, E&F	• Caribbean: Use marginal lands for bioenergy (Mohan 2025) • Central America: Agro-forestry for dual benefits (Villanueva-González 2024) • South America: Integrate biofuel into existing pasture and avoid high-biodiversity areas (Escobar et al. 2024)
Agricultural production grows 22%. (Technology-focused pathway)	Increased output may intensify pressure on ecosystems if not decoupled from land use.	Decouple productivity from land expansion via regenerative and high-efficiency practices.	K&I, C, G	• Caribbean: Emphasize local food systems (Hernández-Moreno et al. 2024) • Central America: Promote soil restoration (Blanton et al. 2024) • South America: Incentivize no-deforestation supply chains and land-use monitoring (Lambin 2022)
Forest area remains stable (+1%). (Behaviour-focused pathway)	Land cover maintained through conservation and reforestation efforts.	Strengthen forest governance, expand protected areas, and support community-led reforestation.	G, S&C, E&F	• Caribbean: Restore mangroves and dry forests (Rull 2023) • Central America: Reconnect Forest corridors (McCullough 2024) • South America: Expand Amazon and Atlantic Forest buffers (Vancine 2024)
Biodiversity index stabilizes (+4%). (Behaviour-focused pathway)	Modest recovery suggests limits in habitat restoration and ongoing fragmentation.	Integrate biodiversity into land-use planning and expand ecological corridors.	G, K&I, S&C	• Caribbean: Protect coral-linked terrestrial habitats (Villarroel-Lamb 2024) • Central America: Scale ecological farming (Ewert 2023) • South America: Prevent fragmentation in biodiversity hotspots (Schmitz 2023)
CCS expansion (+271%); CO_2 emissions (+6%). (Technology-focused pathway)	May reduce emissions but poses land-use and water-use trade-offs for storage sites.	Apply land-use safeguards and integrate CCS with existing infrastructure to minimize land pressure.	G, K&I	• Caribbean: Prioritize offshore or low-impact CCS (Barranco et al. 2024) • Central America: Limit CCS to brownfield sites (Signoria & Barlettani 2023) • South America: Avoid CCS deployment in forested and Indigenous-managed areas (Egerer et al. 2024)

** (Governance-G, Economic and financial-E&F, Social and Cultural- S&C, Knowledge and Innovation- K&I, Capability - C)*

Credit: wirestock/Envato

pressure on pastureland and concerns about emissions and ecosystem fragmentation. Forest area remains stable at one per cent, which reflects effective land-use regulation, but with fewer biodiversity gains compared to the behaviour-focused pathway. Both pathways demonstrate the potential to decouple food production from deforestation, however, the behaviour-focused pathway offers greater co-benefits for carbon storage, biodiversity, and ecosystem restoration (**Table 20.7**).

20.7.4.2 Freshwater quality and availability

The state of freshwater quality and availability in LAC by 2050 depends on how efficiency gains under the technology-focused pathway are balanced with systemic demand reductions under the behaviour-focused pathway (**Table 20.8**). This dynamic is reflected in the need for integrated water governance to manage increasing withdrawals in the technology-focused pathway while advancing improved water use efficiency in the behaviour-focused pathway. In the technology-focused pathway, agricultural intensification and industrial expansion drive a nine per cent increase in freshwater demand, with total withdrawals increasing by 13 km³/year – compared to a global decline of withdrawal of four km³/year. This change is further amplified by a 17 per cent increase in fertilizer use, which exacerbates nutrient run-off and increases eutrophication risks, particularly in agro-industrial regions of Central and South America. Although regional freshwater quality improves by 14 per cent, nitrogen use efficiency declines by 15 per cent, compared to a 21 per cent global improvement.

The two pathways demonstrate that although both improve freshwater outcomes in LAC, only the behaviour-focused pathway achieves meaningful reductions in withdrawals and run-off. Under the behaviour-focused pathway, freshwater withdrawals decrease by 2 per cent, enabled by behavioural shifts, dietary change, and adoption of agroecological practices. Nutrient run-off decreases by 20 per cent, while agricultural water demand decline by 12 per cent, which is higher than global averages. Nonetheless, challenges remain: Wild catch extraction increases under both pathways, increasing by 36 million tons per year in the technology-focused pathway and 92 million tons per year in the behaviour-focused pathway, resulting in additional pressure on coastal and freshwater ecosystems. Outcomes also diverge across subregions, with Central America facing greater water stress, the Caribbean constrained by limited freshwater availability, and South America managing trade-offs between hydropower expansion and watershed protection.

20.7.4.3 Coastal and marine resources

Under the technology-focused pathway, coastal and marine ecosystems in LAC are exposed to increasing nutrient and water stress as accelerated agriculture and bioenergy expansion increase run-off and freshwater withdrawals by 2050 (**Table 20.9**). These pressures pose significant risks to nearshore ecosystems, which could offset gains from reduced fossil fuel emissions and trade. While accelerated agriculture, bioenergy production, and fossil fuel decarbonization collectively lower overall emissions, they also introduce new risks to coastal systems. Fertilizer use is projected to increase by 17 per cent, which could exacerbate nutrient run-off and eutrophication in sensitive marine zones. Bioenergy development could further increase

Table 20.8: Freshwater Quality and Availability related results, response options and regional considerations

Result (% change to 2050)	Freshwater Quality & Availability	Response Option	Levers*	Subregional Considerations/Action
Water quality improves (+14%), but nutrient run-off remains high. ***(Technology-focused pathway)***	Moderate water quality gains, but high nutrient loads continue to stress freshwater ecosystems, particularly in agriculturally intensive areas.	Expand riparian buffers and implement precision nutrient management strategies.	G, K&I, C	• Caribbean: coastal nutrient run-off control (Bolaños-Alvarez et al. 2024); • Central America: upstream pollution reduction (Gu et al. 2023); • South America: target intensive farming regions (Grondona et al. 2023).
Water use in industrial processes increases (+15%) ***(Technology-focused pathway)***	Increased pressure on water resources from industrial processes may reduce water availability, especially in already water-stressed regions.	Adopt water reuse systems and industrial water efficiency standards.	G, E&F, K&I	• Caribbean: industries integrate circular water use (Van Hoof et al. 2023); • Central America: prioritize efficiency in agro-processing (Saravia-Matus et al. 2018); • South America: improve management of extractive sectors (Sarmiento et al. 2025).
Water demand in agriculture declines (12%). ***(Behaviour-focused pathway)***	Improved water efficiency in agriculture reduces pressure on freshwater sources, contributing to long-term water availability.	Support water-saving irrigation technologies and sustainable land management.	E&F, K&I, C	• Caribbean: scale drip irrigation and rainwater harvesting (Van Hoof et al. 2024); • Central America: scale rainwater harvesting (Stewart et al. 2021); • South America: invest in large-scale irrigation retrofits (Houspanossian et al. 2023).
Nutrient run-off declines (20%) ***(Behaviour-focused pathway).***	Reduced run-off enhances water quality, particularly in river basins vulnerable to agricultural pollution.	Promote agroecological practices and vegetative buffer zones.	S&C, G, K&I	• Caribbean: enhance agroecological zones (Alexandre et al. 2021); • Central America: integrate landscape restoration (Kumar et al. 2022); • South America: target degraded agricultural lands (Zalles et al. 2021).
Nitrogen (-25%) and phosphorus (-19%) ***(Behaviour-focused pathway)***	Lower nutrient concentrations help restore freshwater bodies and reduce eutrophication, supporting aquatic ecosystem health.	Strengthen nutrient management regulations and monitoring systems.	G, K&I, E&F	• Caribbean: nutrient monitoring systems (Clark et al. 2022); • Central America: enforce conservation buffer zones (Sze et al. 2022); • South America: support farmer-led forest monitoring initiatives (Londres et al. 2023).

Result (% change to 2050)	Freshwater Quality & Availability	Response Option	Levers*	Subregional Considerations/Action
Agricultural production grows 22% (versus 36% World), far below Current Trends (53%). (Technology-focused pathway)	Increased agricultural activity may heighten water use and run-off without parallel improvements in water management practices.	Incentivize climate-smart agriculture and improved watershed governance.	E&F, G, K&I	• Caribbean: integrated water r esource management (Roopnarine et al. 2021); • Central America: regulate fertilizer run-off (Bundschuh et al. 2021); • South America: enforce basin-level governance mechanisms (Espíndola & da Silva 2024).

** (Governance-G, Economic and financial-E&F, Social and Cultural- S&C, Knowledge and Innovation- K&I, Capability - C)*

freshwater withdrawals by 13 km³/year, which could exert additional pressure on coastal aquifers. Although coal use decreases by 87 per cent and oil use by 43 per cent, oil trade would remain a persistent source of marine contamination risk in 2050.

LAC's coastal and marine ecosystems are exposed to divergent pressures under both pathways; however, long-term water quality gains and ecosystem resilience are dependent on aligning marine resource governance with nature-based solutions, reduced nutrient run-off, and sustainable wild catch management. The behaviour-focused pathway emphasizes nature-based solutions, traditional knowledge, and dietary shifts, which could significantly reduce stress on marine ecosystems. The pathway projects a two per cent decline in freshwater withdrawals and a 20 per cent reduction in nutrient run-off, which would improve water quality and lower risks of coastal hypoxia. However, the projected 92 million ton increase in wild catch under this pathway increases concerns of potential overexploitation of marine stocks if not supported by strong fisheries governance.

20.7.5 Strengthening regional linkages

Regional cooperation in LAC can maximize the benefits of both technological and behavioural transformations. Coordinated policies, shared resource management, and harmonized environmental governance can strengthen collective capacity to achieve sustainable development and climate resilience (Mahadeo & Del Savio 2023; Santos & Colgan 2023). Decisions in one domain – such as energy, food systems, or materials and waste management – often produce cascading effects across borders through trade dependencies, ecosystem linkages, and transboundary resource use (IPBES 2024). Strong cooperation mechanisms, including transboundary water management agreements, are critical to reducing conflict risks and protecting shared resources. The Amazon Cooperation Treaty Organization provides a practical example of how regional institutions can mediate competing interests and foster equitable, sustainable management of shared ecosystems (Martynov et al. 2020).

Effective transboundary policy coordination is critical for protecting biodiversity and managing natural resources in LAC. Regional mechanisms such as the Central American Integration System and the Caribbean Community provide platforms to align national strategies, reduce policy fragmentation, and accelerate transitions under the technology-focused and behaviour-focused pathways (Echebarria Fernández 2021; De Marco et al. 2023; Fernandes et al. 2024). Successful models already exist: the Caribbean Large Marine Ecosystem and Adjacent Regions initiative demonstrates how coordinated marine protection policies can strengthen conservation outcomes and promote sustainable use of shared marine resources (Ganase et al. 2023). Scaling such cooperative frameworks will be essential for addressing cross-border ecological challenges and advancing regional resilience.

Regional collaboration in energy systems offers a unique opportunity to harness the renewable energy growth projected under both the technology-focused and behaviour-focused pathways. Shared infrastructure – such as interconnected smart grids and regional energy markets – can enhance system efficiency, balance supply across countries, and strengthen energy security while reducing greenhouse

Table 20.9: Coastal and Marine Resources-related results, response options and regional considerations

Result (% change to 2050)	Coastal and Marine Resources-related results, response options and regional considerations	Response Option	Levers*	Subregional Considerations/Actions
Water quality improves (+14%), but nutrient run-off remains high. ***(Technology-focused pathway)***	Moderate improvements in marine water quality; continued run-off threatens coral reefs and estuaries.	Improve nutrient management in upstream agriculture and expand buffer zones.	G, K&I, E&F	• Caribbean: Strengthen coastal buffers to protect coral systems (Soanes et al. 2021); • Central America: Enforce riparian buffers in agro-industrial zones (Saravia-Matus et al. 2018); • South America: Target nutrient hotspots in river basins (Sheikholeslami et al. 2024).
Landfill waste rises (+9%) due to increased industrial activity. ***(Technology-focused pathway)***	Increased leachate and plastic pollution impacting coastal ecosystems.	Scale landfill regulation and invest in waste diversion infrastructure.	G, E&F, C	• Caribbean: Prioritize coastal landfill closures (Nicholls et al. 2021); • Central America: Improve rural landfill management (García et al. 2022); • South America: Expand urban waste sorting and capture (Ferronato et al. 2021).
Industrial recycling rates improve (+13%) ***(Technology-focused pathway)***	Reduced coastal waste leakage but limited impact without marine-focused systems.	Incentivize industrial recycling linked to coastal protection schemes.	E&F, K&I	• Caribbean: Promote sustainable industrial practices in port cities (Vera et al. 2023); • Central America: Build recycling value chains in coastal regions (Soto-Rios et al. 2023); • South America: scale marine litter programmes (Belli et al. 2024).
Nutrient run-off declines (–20%), reducing freshwater contamination. ***(Behaviour-focused pathway)***	Lower nitrogen loads in river mouths improve estuarine health and mangrove systems.	Promote regenerative agriculture and nutrient recycling practices.	K&I, G, S&C	• Caribbean: Expand composting and regenerative agriculture (Gallego-Schmid et al. 2024); • Central America: Incentivize nutrient management for smallholders (Chivenge et al. 2021); • South America: Integrate nutrient reduction into watershed plans (Pacheco et al. 2021).
Nitrogen (–25%) and phosphorus (–19%) levels decrease, protecting water bodies. ***(Behaviour-focused pathway)***	Eutrophication risk falls in key deltas and bays, supporting fisheries recovery.	Regulate fertilizer inputs and promote agroecological nutrient use.	G, K&I, E&F	• Caribbean: Monitor nutrient flows into freshwater and marine ecosystems (Londres et al. 2023); • Central America: promote agroecological practice (Alexandre et al. 2021); • South America: Scale transboundary nutrient management system (Pacheco et al. 2021).

Result (% change to 2050)	Coastal and Marine Resources-related results, response options and regional considerations	Response Option	Levers*	Subregional Considerations/Actions
Waste generation decreases (–19%) (Behaviour-focused pathway)	Less solid waste entering waterways and coasts; improved marine habitat quality.	Implement upstream consumption reduction and recycling incentives.	S&C, G, K&I	• Caribbean: Support zero-waste coastal tourism initiatives (Wang et al. 2021); • Central America: Establish circular industries in rural areas (Bundschuh et al. 2021) • South America: Strengthen municipal waste collection in coastal cities (Ferronato et al. 2021).

** (Governance-G, Economic and financial-E&F, Social and Cultural- S&C, Knowledge and Innovation- K&I, Capability - C)*

gas emissions (Levy et al. 2023). Such cooperation is essential to achieving regional decarbonization targets and advancing broader sustainable development objectives. Beyond energy, coordinated strategies, harmonized standards and cross-border regulatory frameworks for managing pollution and waste are increasingly urgent, particularly as material circularity expands and iron ore recycling rates increase. Investments in renewable energy – including binational hydropower projects such as the Itaipu Binational Dam, the Yacyretá Dam, and the Binational Border Hydropower – demonstrate the potential for multiple co-benefits across the food, energy, water, climate, and biodiversity nexus (Berkhout and Warner 2023; IPBES 2024). Achieving these outcomes depends on regional cooperation that safeguards human rights (Reyes-García et al. 2022; Aguilera 2023) and empowers Indigenous Peoples. Additionally, green investment strategies supported by international cooperation (Battistello Espíndola and Batista da Silva 2023) can lead to significant advances in sustainable technology and infrastructure development (Yalew et al. 2020).

20.7.6 Conclusion

Achieving a resilient, equitable, and climate-smart future in LAC by 2050 requires integrated reforms across economic, financial, and governance systems. Under Current Trends, the region faces irreversible environmental degradation and compounding socioeconomic risks by mid-century. Strategic investments in resilient infrastructure, fiscal realignment, and green financial instruments – including social protection systems, debt-for-nature swaps, and sustainable bonds – can enhance financial stability and buffer systemic shocks. Mechanisms such as sovereign risk pools, public-private partnerships, and carbon pricing offer scalable tracks to mobilize capital and accelerate low-carbon transitions. Transformational change in LAC also requires sectoral shifts aligned with both Behaviour-focused and Technology-focused Transformation pathways. Reversing environmental degradation in LAC by mid-century hinges on strengthening governance and integrating sustainability practices to halt deforestation, restore degraded landscapes, and reduce pollution. Circular economy strategies – such as biogas production, regenerative agriculture, and closed-loop manufacturing – offer actionable solutions to waste and pollution challenges while creating jobs and resilient supply chains. Smart electrification through decentralized renewable energy and regional cooperation supports rural energy access and reduces fossil fuel dependency, particularly in small island and underserved communities. In food systems, integrated approaches centred on agroecology, Indigenous stewardship, and sustainable supply chains can restore ecosystems and strengthen food security. Collectively, these cross-sectoral actions demonstrate how LAC can align economic transformation with environmental sustainability and social inclusion to address the multiple crises facing the region.

20.8 Western Europe and Other Groups

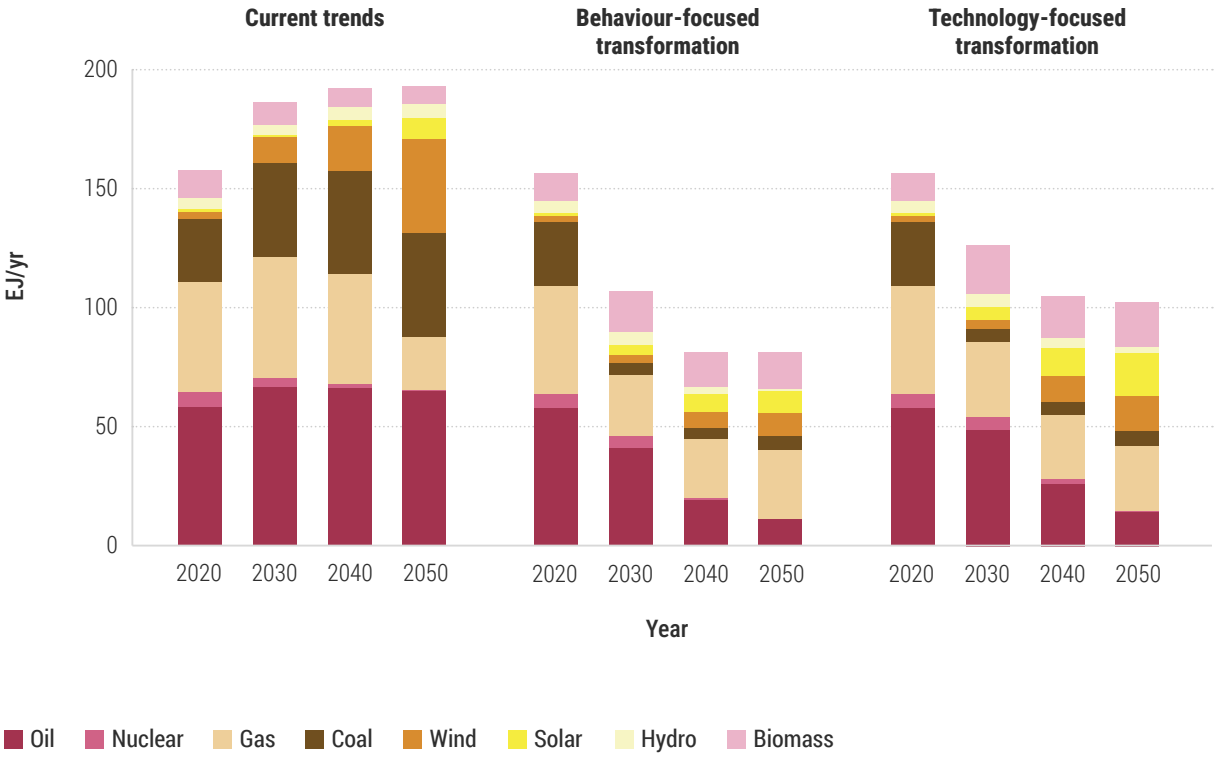
20.8.1 Introduction

The global environmental crises adversely affect countries of the Western Europe and Other Groups (WEOG) through weakened ecosystem function (World Wide Fund for Nature [WWF] 2022) and reduced human well-being (IPCC 2021; IPCC 2022; European Commission 2022). WEOG is experiencing the interlinked crises of impaired biodiversity, climate change-driven extreme events, air and water pollution and excessive waste production. Heat-related mortality was extreme in Europe in 2022 and recent fires in Los Angeles resulted in damages that likely exceed US$250 billion. While WEOG countries have the capacity to protect their populations from these existential threats, aged infrastructure and increasing intersectional inequalities contribute to increased vulnerability for some communities and groups. The challenges of the global environmental crises are the indirect results of a failure of governance at many geographic scales. To mitigate these changes, key priorities for WEOG should involve the five systems investigated in the Outlooks Part of GEO-7, that require five lines of action.

- Energy System: Decarbonization, rapidly reducing carbon emissions through renewable energy adoption and carbon dioxide removal strategies, electrifying transportation, and enhancing energy efficiency {16.2-16.4}.
- Food System: Promoting sustainable farming practices that prioritize soil and livestock health, reduce chemical inputs, protect water resources, and reduce air pollution. Shifting towards more plant-based diets and reduce food loss and waste and conserving Indigenous Peoples' and local communities' sustainable and adaptive ways of life {17.2.1-17.2.5}.
- Material System: Shifting towards circularity that minimizes waste and maximizes resource efficiency.
- Economic and Financial System: Increased role of government towards revising and incentivizing taxes and subsidies towards sustainable and inclusive practices {14.3-14.6}.
- Environmental System: Protecting and restoring ecosystem health.

20.8.2 Technology-focused Transformation Pathway

Technology-focused pathways for transformative, integrative and cross-sector solutions suitable for WEOG can address the global environmental crises moving forward.



20.8.2.1 Transitions to renewable energy

The technology-focused pathway enables WEOG countries to achieve rapid carbon emission reductions through a transition to renewable energy, carbon dioxide removal strategies, electricity-based transportation, and enhancing energy efficiency. To achieve this, the following actions may be needed {16.2-16.4}:

- Complete the energy transition away from fossil fuels well before 2050.
- Invest in renewable energy infrastructure such as insulation, heat pumps, solar energy, wind power, green hydrogen, geothermal, and tidal energy.
- Invest and implement carbon dioxide removal strategies and technologies such as direct air carbon capture and storage and bioenergy with carbon capture and storage.
- Develop the workforce through education and training of people to implement the above.
- Improve governance by establishing monitoring capacity, target definition, and effective incentives, taxes, and subsidies.

Primary energy use is projected to decline in both the technology-focused and the behaviour-focused pathways. Furthermore, the share of renewable energy – solar, wind, hydro and biomass – in primary energy use in the WEOG region is expected to rise (**Figure 20.28**). Modelling foresees the share of carbon capture and storage (CCS) technologies in energy production to rise to 34 per cent by 2050, however there is a caveat in this forecast as this technology has not yet been implemented in practice (**Figure 20.28**). The IPCC models that meet the 1.5°C target include direct air carbon capture and storage and bioenergy with carbon capture and storage with significant contributions from agriculture, forestry and other land uses. However, current rates of CCS are far below the potential modelled in the IPCC pathways, even if those pathways show that the CO_2 storage requirement is smaller than

Figure 20.28: Primary energy use for the three pathways in Western Europe and Other Groups

the geological CO_2 storage capacity (IPCC 2022). Bioenergy with carbon capture and storage bears the potential risk of reducing biodiversity by introducing intensive monoculture plantations. Therefore, careful land-use planning is required to leverage synergies that support biodiversity while mitigating climate change (IPCC 2022).

The WEOG countries have taken measures in this direction by committing to the energy transition and announcing political agendas focusing on renewable energy and increased energy efficiency. The European Union fixed its goal of carbon neutrality at 2050 (European Commission 2022), and New Zealand and Australia demonstrate significant commitments to renewable energy (DCCEEW 2022; MBIE 2023). Thus, policies are focusing on the energy transition, while the use of renewable energy, especially in transport and heating, still poses challenges. This is evident in the European Union, where planned renovation rates fell short compared with needs (Maduta et al. 2023). As well, carbon dioxide removal measures are falling short of targets (Galán-Martín et al. 2021).

20.8.2.2 Sustainable agriculture and food system

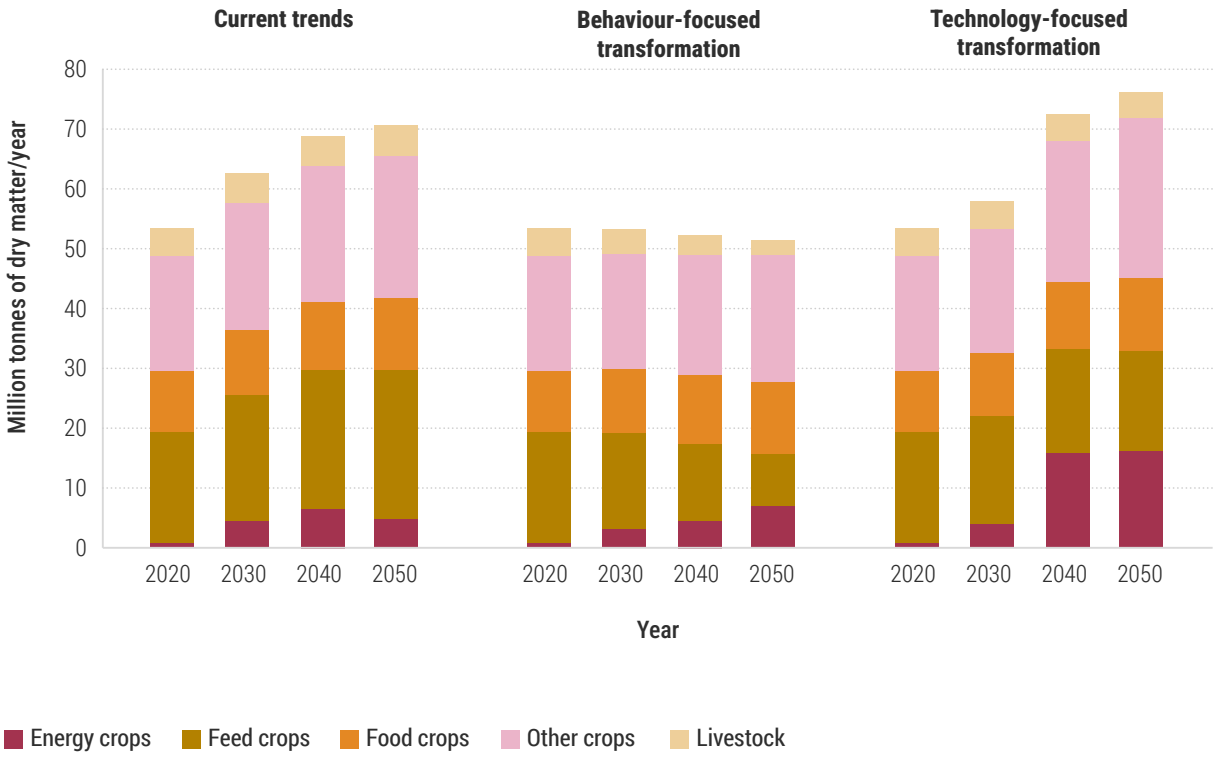
If the WEOG countries embrace the promotion of sustainable food production practices and shift towards more sustainable diets along the technology-focused pathway, the following actions should be considered {17.2.1-17.2.5}:

- Prioritize preserving and improving soil and livestock health
- Reduce chemical inputs
- Protect water resources
- Reduce air pollution
- Develop new plant varieties or use indigenous varieties suited to emergent environmental conditions
- Diffusion of innovative production techniques

The technology-focused pathway for the food system is guided by principles of efficiency, intensification, and technological intervention. Solutions need to be found regarding the loss of arable land, the reduction of available fresh water, reduction of food loss, the rise of food demand, and food waste. New plant varieties will be developed through genetic selection or bioengineering with the aim to be better suited to emergent environmental conditions and to have higher yields and provide better nutrition. Innovative production techniques for soil, water, and crop management, such as precision agriculture and micro irrigation, will be applied. Food production will pursue a form of automation, relying on environmental and crop and livestock monitoring, the use of remote stations, rovers, drones, and artificial intelligence applications that complement human action.

Efficiency enhancement of the food supply chain, with a focus on limiting waste, will take place through technological intervention. In the face of growing demand for protein products, novel foods will be introduced once they are developed based on plant, animal and insect proteins, as well as the introduction of new varieties through genetic selection (**Figure 20.29**).

The modelling results suggest agricultural demand and production will increase, while land cover will remain constant due to increases in production efficiency and sustainable land management practices. Food prices will rise by 28 per cent from 2020 to 2050 and this pathway has the highest increase in food prices.



20.8.2.3 Economic and financial systems

If WEOG countries embrace the technology-focused pathway to fully embrace circularity, implementation of the following actions may be needed {14.3-14.6}:

- policies that support a transition to circularity
- eco-taxation
- specific waste reduction targets

In 2020, the European Union approved the Circular Economy Action Plan, aimed at imposing sustainable practices across various sectors. It enforces eco-design directives for energy-efficient products, champions consumer rights for product repair, and advocates for updated directives that target industrial emissions and urban wastewater treatment (Watkins and Meysner 2022). European countries have been slow to implement

Figure 20.29: Agricultural demand for the three pathways in Western Europe and Other Groups

circular economy technologies, and it is unlikely that a doubling of recycled materials in the system by 2030 will occur (ECA 2023). Similarly, in the United States, the Environmental Protection Agency is developing new circular economy strategies, having issued drafts for comments (US-EPA 2022).

20.8.2.4 Conservation and restoration of nature

Technological transformation in food, energy, material, and financial systems can enhance sustainability by promoting resource efficiency and reducing waste. Innovations in agricultural practices can lead to lower emissions and better soil health {18.2.3; 18.2.4}. Renewable energy sources and smart grids lower greenhouse gas emissions. Advancements in materials science foster the development of biodegradable, environmentally benign, and sustainable products. Improved financial systems incentivize eco-friendly investments and circularity practices. Together, these transformations contribute to a more resilient ecosystem.

20.8.2.5 Economic and financial system reforms

The financial system likely holds many of the primary levers of control for bringing about the desired transformations of the energy, material, food, and environmental systems. The WEOG countries represent roughly 10 per cent of the world's population while they own almost 60 per cent of the world's wealth and enjoy more than half of the world's annual income. Consequently, WEOG countries have a responsibility to demonstrate and facilitate desired transitions at home and abroad. Chapter 11 and Chapter 14 identify five solution pathways {14.3 to 14.6}:

- Internalizing externalities – getting-prices-right
- Green finance – getting-incentives-right
- Regulations to foster green behaviour and increased role of government
- Circularity informed by macrolevel energy and material accounting
- Introducing carbon tax and green tax to incentivize the private sector for innovative financing of circularity measures such as waste-to-energy

To varying degrees in the WEOG region, existing economic systems are currently accelerating economic

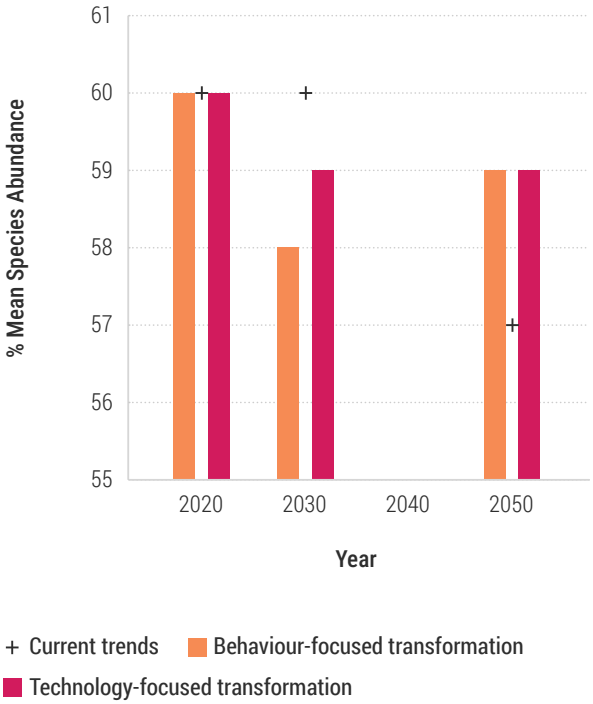
inequality, social injustice, and environmental degradation (Piketty 2014; US-EPA 2022). It is becoming increasingly clear that a new economic operating system is needed that adopts elements of all five of the solution pathways. Research that integrates nature and ecosystem services into a food-water-energy nexus helps policymakers advance just transitions (Subedi et al. 2020). It is likely that the geographic extent of policies will vary but WEOG countries need to design, experiment with, and facilitate bold new policies and practices to foster these systemic changes. Some areas of promise are:

Increase the role of governments to use subsidies as green finance and taxes as disincentives for certain unsustainable economic activities, while internalizing external costs and incentives for labelling, certification, and carbon neutrality.

Reorient the international financial system towards achieving the SDGs particularly those related to human health and well-being. This would likely involve WEOG governments reducing risks associated with foreign direct investment in low-income countries, cancelling debt, and developing and expanding financial tools used for redistribution and investment, such as the EU's Green Bonds.

20.8.2.6 Technology-focused pathway implications

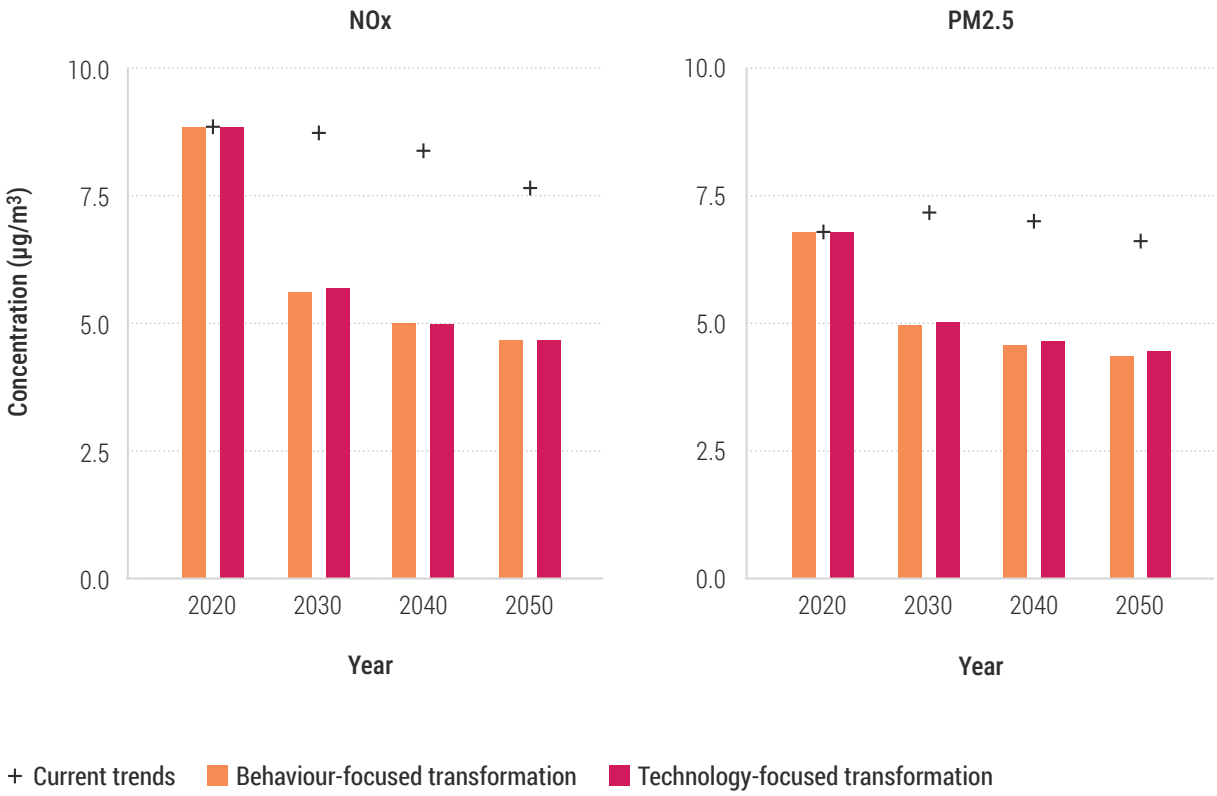
These technology-focused pathway actions can have positive and negative socioeconomic and environmental implications that should be carefully monitored.



Implementing the technological pathway may stimulate economic growth and job creation and enhance human well-being. Increased use of remote-sensing technologies can contribute to behavioural change around renewable energy uptake. Increasing penetration of renewable energy requires significant policy interventions (Chen et al. 2019). Circularity opens job opportunities in repair, refurbishment, and recycling. This boosts social resilience and inclusivity (McGinty 2021); however, there is limited knowledge of the magnitude of these opportunities (Aguilar-Hernandez et al. 2021). Economic system shifts will support progress towards a just, sustainable, and desirable future (IPBES 2019; Turnhout et al. 2021). Legal frameworks and eco-taxes can encourage eco-friendly practices and discourage harmful products.

There are many positive benefits, however unintended negative consequences could include under-employment, work-profile obsolescence, and increasing inequality.

20.8.2.6.1 Environment aspects



The technology-focused pathway can increase resilience, decrease GHG emissions, and better improve ecosystem and human health. Renewable energy shifts should decrease GHG emissions and likely reduce threats to the environment generally (Gielen et al. 2019). The circular economy and extended product-lives can lead to improved water quality, reduced pollution, and greater biodiversity (**Figure 20.30**) and to improved air quality (**Figure 20.31**), fostering a healthier, more sustainable environment. Direct interventions to restore and encourage biodiversity have been shown to be viable (Pereira and Navarro 2015). This approach can conserve resources, prevent habitat destruction, and cut pollution. The existing economic system fails to account for or acknowledge that our economy, our society, and our civilization fundamentally depend on the natural world to exist. Thus, economic

Figure 20.30: Terrestrial biodiversity for the three pathways in Western Europe and Other Groups

Model output data was not available for biodiversity for the year 2040 and for clear comparison across the years, the values of the vertical axis start at 55% MSA

Figure 20.31: Air pollution for the three pathways in Western Europe and Other Groups

system shifts involve increased acknowledgement of the value of nature.

20.8.3 Behaviour-focused Transformation Pathway

Behaviour-focused pathways for transformative, integrative and cross-sector solutions suitable for WEOG that can address the global environmental crises moving forward are described below:

20.8.3.1 Transition to renewable energy

Under this pathway, WEOG countries achieve decarbonization, rapid carbon emission reduction through renewable energy adoption, carbon dioxide removal strategies, electrification of transportation, and enhanced energy efficiency. These can be achieved through {16.2-16.4}:

- Reduction of home energy usage, with the adoption of low-energy consumption and energy-efficient technologies and appliances, home insulation, and reduction of water heater temperature.
- Shift towards domestic prosumerism, adopting domestic energy production and storage solutions, implementing rainwater harvesting, and growing home gardens.
- Modal shifts in urban mobility and urban planning, mobility shift towards more public transport.
- Reducing demand on energy, materials, food, and other environmental systems by eliminating non-essential and wasteful consumption.

The modelling results suggest that following the behaviour-focused pathway, primary energy production decreases by 41 per cent by 2050, compared to 2020. The share of renewables increases but is lower than the technology-focused pathway for WEOG.

The WEOG countries are transitioning along the behaviour-focused pathway as rising costs are pushing consumers to adopt energy-efficient solutions (Camarasa et al. 2021). Prosumer behaviours have spread, showing an emergence of new attitudes towards domestic energy production

(Parra-Domínguez et al. 2023). Similarly, an increasing interest in home and collective vegetable gardens reflects concerns related to food scarcity, food and environmental contamination, and climate change (Raneng et al. 2023). These events emerge while cities across the region are implementing urban strategies responding to demand for more sustainable urban spaces (Alberti 2023).

20.8.3.2 Sustainable agriculture and food system

Under the behaviour-focused pathway, benefits will be achieved by the shift towards more sustainable diets and by the reduction of food losses and waste. These can involve arrangements such as farm-to-fork strategies that bring food producers closer to consumers through knowledge campaigns on regional food production, urban and peri-urban agriculture, permaculture, and local marketing.

As consumers reduce household food waste and diversify their diets, they gradually emerge as prosumers. This results in a higher demand for plant-based food and lower demand for livestock products. Polycropping, agroforestry, integrated crop and livestock systems, organic and agroecological farming, urban agriculture, use of local varieties, and development of organic value chains are ways forward. This will reinforce the resilience of food systems. The risks of pests and diseases and the need for external inputs are reduced through the practice of integrated pest management and biological control of pests and diseases {17.2.1-17.2.5}.

20.8.3.3 Circular economy and pollution control and prevention

WEOG countries can embrace the behaviour-focused pathway to implement circularity through waste/material system transformation for which the following actions may be considered:

- Shifting towards green consumerism (White et al. 2019), prioritizing sustainable and eco-friendly products and services
- Downscaling of consumption patterns in a shift towards sustainable lifestyles that prioritize quality over quantity, sharing, and reducing material consumption
- Fostering local sustainability movements to raise the general awareness of consumers to ensure that all WEOG members achieve SDG 12 addressing sustainable consumption and production
- Ensuring that the Industrial Production Processing and Utilization (IPPU) sector achieves carbon neutrality by 2030 as the IPPU is one of the high carbon emitting sectors.
- Prioritizing the purchase of recycled materials over virgin materials.

For over two decades, practices of green consumerism have proliferated in WEOG countries (Sachdeva et al. 2015). There has been a notable increase in consumer awareness regarding sustainability issues (Bassi 2023). This shift has intensified the need for regulatory oversight of advertising messages, as acknowledged by the European Circular Economy policy (Watkins and Meysner 2022). A discernible change in consumption patterns towards high-quality and sustainable products is evident in markets such as fashion and food, particularly among more affluent segments. Additionally, practices of the sharing economy have become widespread in WEOG countries. These sharing economy practices are linked to the growing utilization of online exchange platforms (Panniello et al. 2022). This proliferation is generating new regulatory needs for these emerging market forms (European Commission 2016).

20.8.3.4 Economic and financial system reforms

There are three fundamental ways in which the Behaviour-focused pathway will interact with the financial system:

- A change in our understanding of the value of nature and the nature of value
- A rebalancing of the public and private spheres that is accompanied by a rebalancing of cooperation and competition as producers of value
- A shift away from the growth imperative and a move towards designing an economy to produce sustainable well-being rather than ever increasing GDP (Costanza 2023)

Box 20.5 Indigenous Knowledge, technology, behaviour and governance: Sustainable whaling

Indigenous Knowledge is a knowledge-belief-practice complex (Berkes 2010) in which behaviour, technology, and other cultural domains (e.g. ethics, governance) are intricately intertwined. For example, the toggle harpoon, perfected by Indigenous Peoples of the Arctic for hunting marine mammals, became associated with a rich and sustainable regional economy and culture that has persisted for millennia. However, the harpoon's mechanization and unregulated industrial application by commercial whalers in the 19th century proved unsustainable, endangering many whale populations by the 20th century and setting the stage for a conflict between Western science and Indigenous Knowledge over the governance of subsistence whaling.

The Alaska Eskimo Whaling Commission (AEWC) was established in 1977 following an IWC ban on bowhead whaling. The ban was based on a survey conducted without consultation with Indigenous hunters concerning the timing and pathways of the bowhead migration, resulting in an estimate of the Bering Sea stock of bowheads far lower than the actual population. Based on Indigenous Knowledge of when, where, and how to count whales, a resurvey was carried out. This IK-informed study found the population to be considerably higher than the original survey supporting the ban.

Consequently, an exemption to the whaling ban was crafted for Alaskan Inupiaq and Siberian Yupik villages, based on a sustainable hunting quota for customary subsistence uses. Thereafter, AWEC was given a role on the scientific committee of the IWC that monitors populations and sets catch quotas. Local knowledge governance of whaling is a major conservation success story for both the bowhead whale and the Indigenous whaling cultures of Alaska and beyond (cf. Huntington et al. 2021).

Since 1981, the AEWC has carried out management and enforcement responsibilities pertaining to sustainable and ethical bowhead whale hunting under a cooperative agreement with the US government and in compliance with IWC regulations.

The AEWC case shows why subsistence whaling still makes sense in the modern world of industrialized, agriculturally oriented food system. It meets the food security criteria of accessibility, affordability, availability and desirability (GPAFSN 2020).

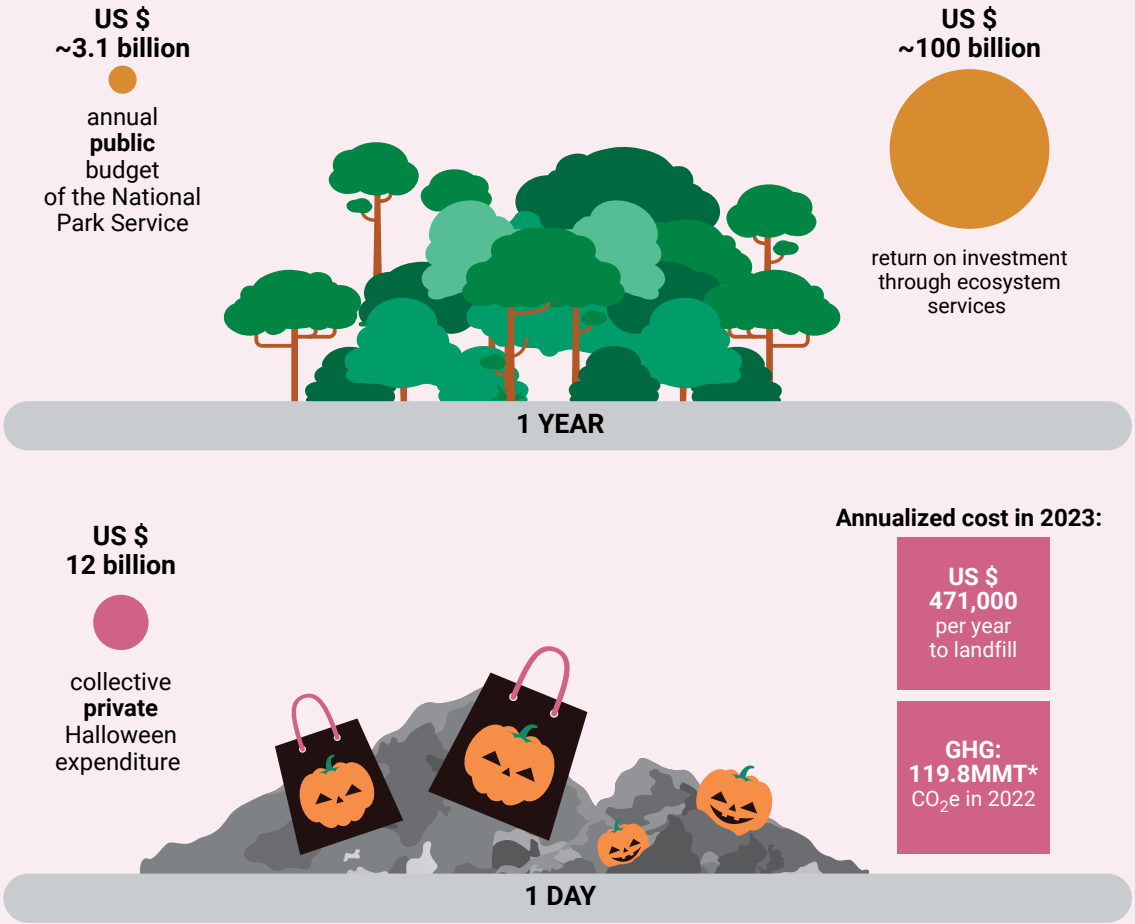
It is a sustainable niche that supports Indigenous food sovereignty and circular economies, ecocultural health and diversity, and traditional knowledge and values (cf. Burn Silver et al. 2016). More broadly, Indigenous whalers' knowledge has proven indispensable to contemporary understanding and responses to climate change in the Arctic. Indigenous-led monitoring programs are tracking Arctic environmental changes and their impacts. With scientists, Indigenous community members co-produce and interpret data on permafrost and sea ice thickness, animal migration patterns, and weather conditions to arrive at nuanced, locally contextualized understandings of climate impacts. This approach is being scaled up through The Arctic Council's Arctic Monitoring and Assessment Programme (AMAP) which collaborates with Inuit communities to gather data on environmental changes and their effects on communities (AMAP 2024). Paired with co-governance, this co-learning aids in developing more effective resilience and adaptation strategies tailored to local conditions throughout a region that is experiencing among the world's highest rates of environmental change. It is a case where incorporation of Indigenous Knowledge has proven transformative for environmental research, monitoring, and adaptive governance.

Credit: Galyna_Andrushko/Envato

In addition, circular economy practices will produce new jobs.

Currently nature is undervalued. Multiple conceptualizations of value, including non-material aspects such as the intrinsic values of ecosystem goods and services, can be internalized by the nature and climate finance system. This will provide incentives for sustainable consumption and production of natural resources (IPBES 2022). Therefore, changes to our financial system must recognize the immense value of functioning ecosystems and incorporate the value of the natural world in a serious way. Modelling projections suggest the behavioural transformation will involve a less urbanized world with greater societal awareness of humanity's fundamental dependence on functioning ecosystems and a stable climate. The WEOG countries are some of the most urbanized in the world. This is a challenge for WEOG countries because increasing levels of urbanization are contributing to increasing disconnection from nature (Turner et al. 2004). There is growing recognition that Indigenous People have a greater appreciation of human connection to, and dependence upon, the natural world according to the IPBES report on valuation of biodiversity and ecosystem services assessment (IPBES 2019). Changes to our financial system that will increase resilience, efficiency, and equity involve rediscovering, internalizing, and formally recognizing the value of the natural world and developing mechanisms to share the wealth of the natural world more equitably and democratically. There are myriad policies to achieve these objectives which will likely vary in scope, geographic extent, and cost.

20.8.3.5 Conservation and restoration of nature



Behavioural and lifestyle changes, such as adopting plant-based diets, reducing energy consumption, and embracing minimalism, can significantly alleviate pressure on environmental systems. By prioritizing sustainable choices – such as using public transport, supporting local economies, and minimizing waste – individuals can reduce their carbon footprints and resource use. Engaging in community initiatives and advocating for eco-friendly policies can further amplify these efforts, creating a ripple effect that promotes collective action. Ultimately, these changes foster

Box 20.6 The Inflation Reduction Act as an example of financial-system change

One prominent example is the Inflation Reduction Act (H.R. 5376) that the US Congress passed into law in August 2022. Although its name suggests that it is an inflation control act, its actual intent and impact lie in its capacity to reform key aspects of the financial and regulatory systems in the US (IRS 2022). This legislation incorporates tax incentives aimed at reducing carbon emissions by 40 per cent. It promotes renewable energy and energy efficiency, as well as economic equity by taxing large corporations and the ultrawealthy while avoiding new taxes on families earning less than US$400,000. Aligning financial incentives with environmental goals can stimulate investment in sustainable practices across various sectors of the US economy.

WEOG countries, by transforming their financial systems, can lead by example, inspiring other regions to adopt similar practices. This leadership can facilitate international cooperation on climate initiatives, technology transfer, and SDGs, creating a more unified and inclusive global response to environmental challenges. One specific example that cries for leadership and communication related to the misallocation of resources is the juxtaposition of private spending on the single day of Halloween in the United States of about US$12 billion compared to the entire annual budget of the National Park Service of about US$3.1 billion (**Figure 20.32**).

Figure 20.32: Pumpkins or Parks – Behaviour-focused pathway implications

a culture of sustainability, encouraging industries to adopt greener practices and enhancing overall environmental health.

Changing the financial systems in WEOG countries is crucial for achieving changes in food, energy, material, and environmental systems worldwide. By reorienting financial incentives, WEOG governments can shift how resources are managed.

20.8.3.6 Socioeconomic aspects

The behaviour-focused pathway can have varied social and economic effects on people, particularly in terms of their consumer behaviours. In terms of renewable energy, there could be a shift towards more decentralized energy systems and prosumerism approaches, where consumers install their own renewable energy generation capacity, such as solar panels. These actions may have higher upfront costs but are likely to generate economic returns. Prosumerism raises equity issues, where renters may not be able to become prosumers, disadvantaging them (Dodd and Nelson 2022). Solar panels and electric vehicles may stimulate the circular economy through increased demand for key elements in these products. Regarding urban mobility, this pathway may underline modal shifts towards the use of more public transport and soft mobility, which entails significant health benefits (Zapata-Diomedi et al. 2017; Rodrigues et al. 2020).

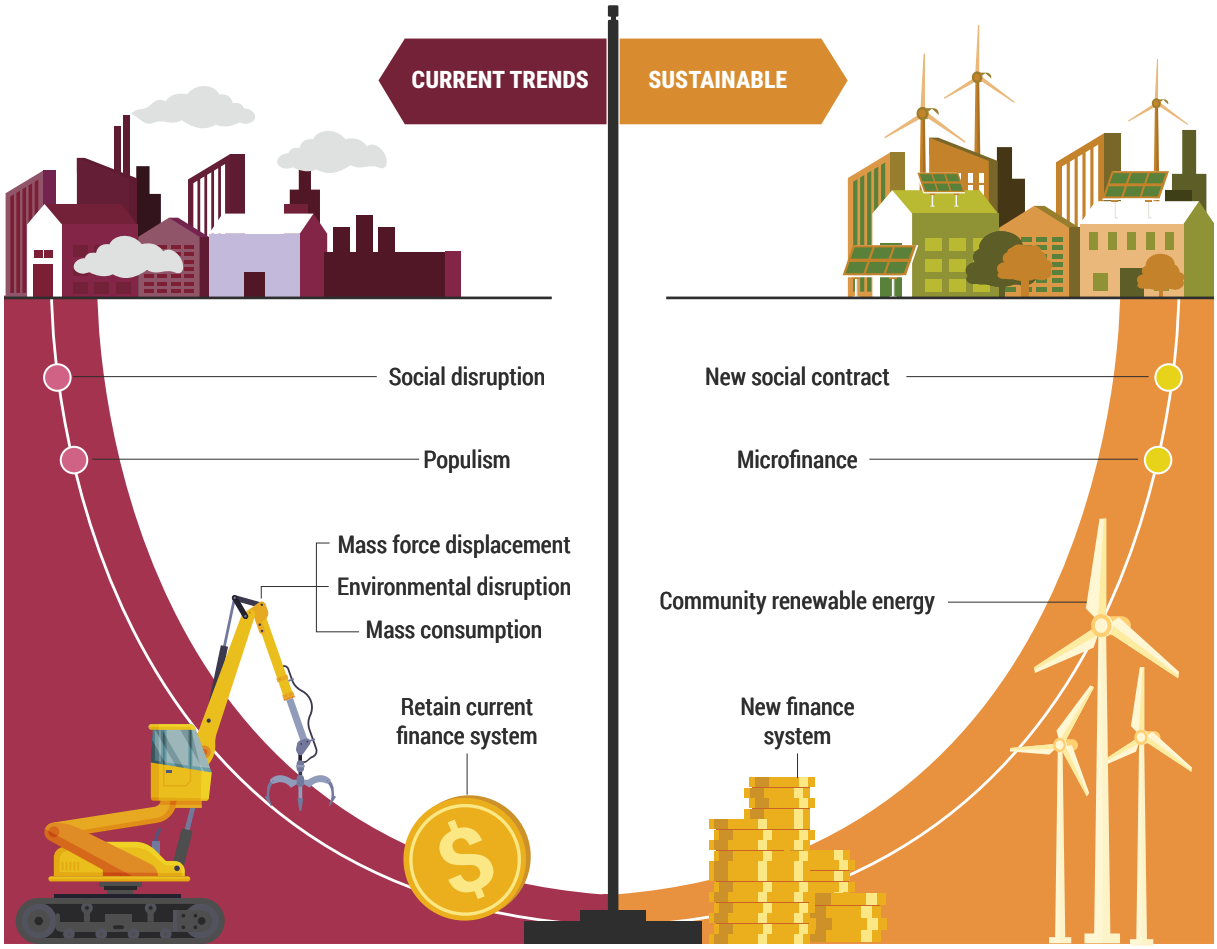
Material systems can promote sustainable lifestyles including gender inclusion and empowerment, reducing socioeconomic effects of consumerism. It aligns purchasing decisions with socioenvironmental values, fostering a cycle of sustainability awareness that leads to healthier and inclusive communities and cleaner environments. This approach particularly engages youth, women and older people ensuring long-term ecological stewardship.

Through changes to the financial system, WEOG countries should model and facilitate the establishment of rules-based systems that foster regionally specific desired changes to food, energy, material, and environmental systems. This will necessitate a change in the mind-set of individuals and policymakers who have been raised in a socioeconomic system that favours competition over cooperation, individualism over collectivism, and exploitation of nature over stewardship of nature.

20.8.3.7 Environmental aspects

The 28th Conference of the Parties to the United Nations Framework Convention on Climate Change (COP28) of the UNFCCC decided to triple the production of renewable energy and double the energy efficiency by 2030. This is expected to help UNFCCC parties achieve another milestone COP28 decision on transitioning away from fossil fuels by 2050 (UNFCCC 2023). The WEOG members are expected to lead in implementing these decisions and achieve targets. Reducing food waste and postharvest production loss can decrease the area needed for agriculture, potentially reducing pressure on biodiversity loss (Guo et al. 2023). Preferences for integrated pest management can deliver lower GHG and nitrogen emissions through decreased livestock production. Large-scale plant protein monocultures may decrease biodiversity and water quality unless agroecological practices are implemented (Bourke et al. 2021).

By reducing consumption and waste, material system changes decrease resource use and environmental degradation as demonstrated by Indigenous Peoples' high circularity practices (Vijayan et al. 2022). Initiatives include minimizing single-use plastics and promoting waste reduction, resulting in cleaner oceans and less landfill waste. Additionally, community-driven efforts enhance local sustainability, while the sharing economy decreases the environmental footprint of production and transportation {18.2.3; 18.2.4}.



20.8.4 Regional priorities, synergies and trade-offs

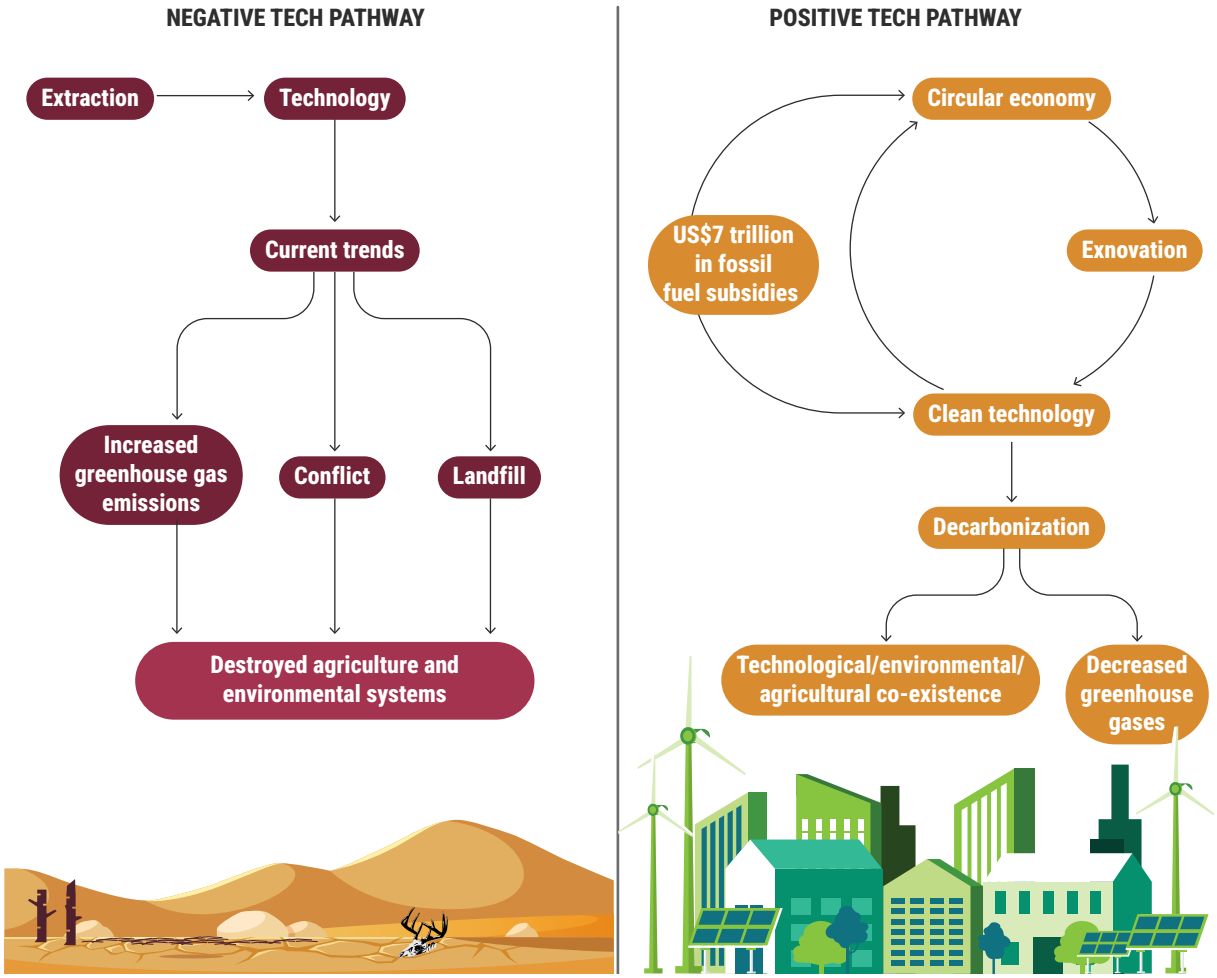
The outlined pathways for societal and environmental transformation carry multifaceted implications that are both promising and challenging (Figure **20.33**, **20.34**).

20.8.4.1.1 Positive societal impacts

- Economic Growth: Industries involved in renewable energy, sustainable agriculture, circularity, and clean technologies experience growth, creating jobs and stimulating innovation.
- Job Creation: The adoption of sustainable practices, such as circularity initiatives and community-based actions, generates employment opportunities.

Figure 20.33: Behavioural-LIFE focused path showing two directions

- Consumer Well-being: Encouraging responsible consumption patterns benefits consumers by reducing the financial strain and health issues associated with excessive and wasteful consumption.
- Education and Awareness: Understanding the impact of consumption on the environment promotes responsible decision-making and sustainable lifestyles.
- Community Engagement: Community-based actions, such as neighbourhood composting programmes, repair cafés, and local swap events, encourage social cohesion and shared responsibility.



20.8.4.1.2 Positive environmental impacts

- Resource Conservation: Resource-efficient manufacturing, recycling, and circularity principles contribute to the conservation of finite resources.
- Waste Reduction: Less waste in landfills and oceans minimizes pollution, preserves natural habitats, and supports biodiversity.
- Greenhouse Gas Emission Reduction: This mitigates climate change and contributes to a healthier planet.
- Pollution Mitigation: Eco-friendly product design and circularity initiatives minimize pollution at various stages of production and consumption.
- Conservation of Ecosystems: Sustainable agriculture practices, such as agroecological farming, prioritize soil fertility, water retention, and biodiversity.

20.8.4.1.3 Challenges and unintended consequences:

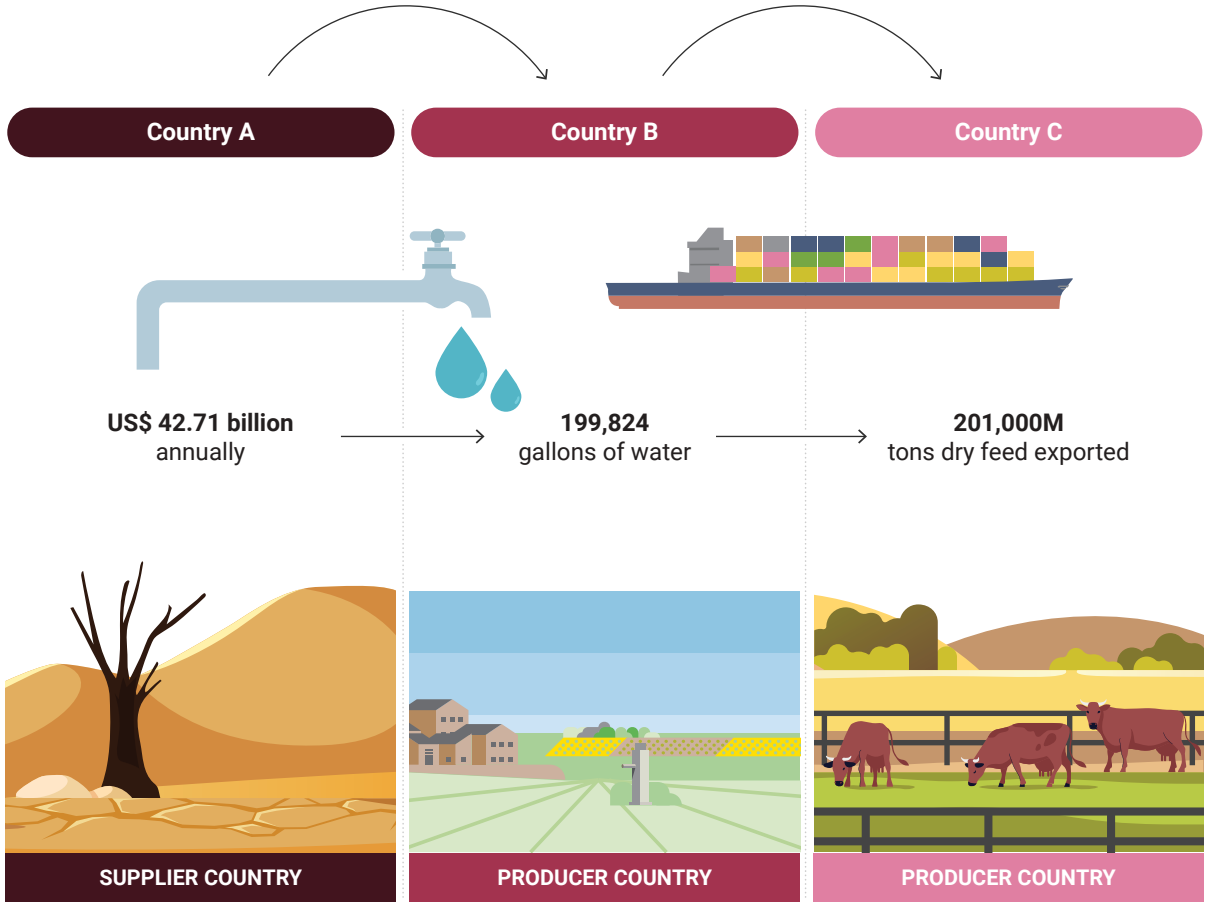
- Economic Challenges: The transition to sustainable practices, particularly in the food system, may lead to higher production costs and

Figure 20.34: Implications from a positive and a negative approach to a technological pathway

potentially increased food prices at the level of individual consumers. Higher food costs are a consequence of internalizing external costs of food production.

- Regional variability: Local specific systems may conflict with the need for standardized quality and quantity required for global trade. Striking a balance between local sustainability and global trade dynamics is a challenge.

- Implementation Hurdles: Effective implementation of these initiatives relies on supportive policies, financial investments, and public engagement. Ensuring that these measures are carried out successfully can be a complex process.



- Equity Concerns: While sustainability efforts aim to benefit society as a whole, there may be equity concerns. Vulnerable communities face barriers in accessing sustainable products and services, potentially exacerbating existing inequalities. Proactive action must be directed towards the inclusion of marginalized groups within the WEOG countries with a focus on gender issues, people with disabilities, cultural minorities, and migrants.

- Transboundary Issues: Money, material, air, energy, and labour cross international boundaries, which raise many moral, ethical, and practical questions with respect to building an integrated social-environmental-economic accounting system that must be resolved (**Figure 20.35**).

20.8.5 Reflection on strengthening regional interlinkages

Energy System and Materials System: Both the technology-focused and behaviour-focused pathways emphasize sustainability through changes in consumption and production. The energy system

Figure 20.35: Transboundary issues, virtual water, and the food-water-energy nexus

needs to transition away from fossil fuels, based on enhanced production and efficient use of renewable energy, while the materials system needs to embrace circularity practices to reduce waste and optimize consumption. The use of sustainable consumption and production and use of energy-efficient technologies is necessary.

Food System and Materials System: The food system transformation means countries must follow a combination of conservation agriculture-based sustainable intensification (CIMMYT 2019) that can scale-up sustainable agriculture practices, including agroecological farming and the use of high yielding native varieties. These practices, together with climate-resilient agriculture, align with the food and materials systems' goals of transformation and sustainability. Additionally, both pathways can address food waste reduction through different approaches including circularity and dietary changes (Agamuthu and Babel 2023; FAO 2023).

Synergy among Food, Environment and Economic Systems-Overall, the solutions can lead to following synergies:

- Both pathways promote resource efficiency, nature protection, and waste reduction, contributing to environmental sustainability.
- Energy systems and the behaviour-focused pathways align in encouraging reduction of energy use, energy conservation, and renewable energy adoption.
- The materials system and the behaviour-focused pathway share goals of promoting sustainable products and consumer education.

In terms of policy implications, it is increasingly recognized that mixtures of policies, particularly price-based instruments, are most effective in achieving SDGs (Lecocq et al. 2022; Stechemesser et al. 2024; Winkler et al. 2024). It is likely that mixtures of policies

rooted in the financial system will be most effective in bringing about desired changes in the food, energy, environmental, and material systems across WEOG. In addition, the success of these policies often have to be fine-grained from sectoral, geographic, and sociodemographic contexts.

20.8.6 Conclusion

A summary of key intervention points is provided in **Table 20.10.** Ongoing support and development of social, economic, and environmental monitoring capabilities is vital for the adaptive management need to face the challenge of the global environmental crises and is an area in which WEOG countries have made significant contributions. Among these, addressing transboundary issues such as migration, nature conservation and pollution control will need strong political will, vibrant regional cooperation and integration of economic and trade policies (McIntyre 2025).

These are the key messages from the WEOG region's perspective:

Energy System:

- Policies should support the adoption of renewable energy sources and energy efficiency measures.
- Incentives for prosumer participation and investment in renewable energy infrastructure are essential.
- Regulations should align with EU climate targets and promote the reduction of energy consumption.

Food System:

- Policies should encourage sustainable farming practices, sustainable plant-dominated diets, and reduced food loss and waste.
- Initiatives promoting direct producer-consumer interaction and local production should be supported.

Table 20.10: Main actions for each system

System	Actions	Actions	Actions	Actions
Energy {16.2-16.4}	Governance and capacity-building	Eco-Taxation and end fossil fuel subsidies	Investment in renewable energy infrastructure	Modal shifts in urban mobility
Food {17.2.1-17.2.5}	Governance and capacity-building	Promote regenerative agriculture	Promote precision agriculture and optimize logistics	Built trust and capacities through communication and food education
Material {15.2.2}	Governance and capacity-building	Implementation of circular economy	Eco-Taxation	Promotion of green consumerism
Economic and Financial {14.3-14.6}	Governance and capacity-building	Green finance	Implementation of economic models to prioritize sustainable well-being over GDP growth	Debt relief for developing countries

- Balancing local production with global trade requirements may require policy adjustments.

Materials System:

- Policies should promote circularity principles, sustainable materials, and extended producer responsibility.
- Eco-taxation and incentives for recycling and reuse can be effective in reducing waste.
- Economic and Financial System:
- Support the introduction of green finance, including eco-taxation, green subsidies, ensuring an inclusive recycling scheme, etc.
- Develop an integrated economic-environmental accounting system that uses economic models that prioritize sustainable well-being over GDP.
- Provide debt relief for developing countries.

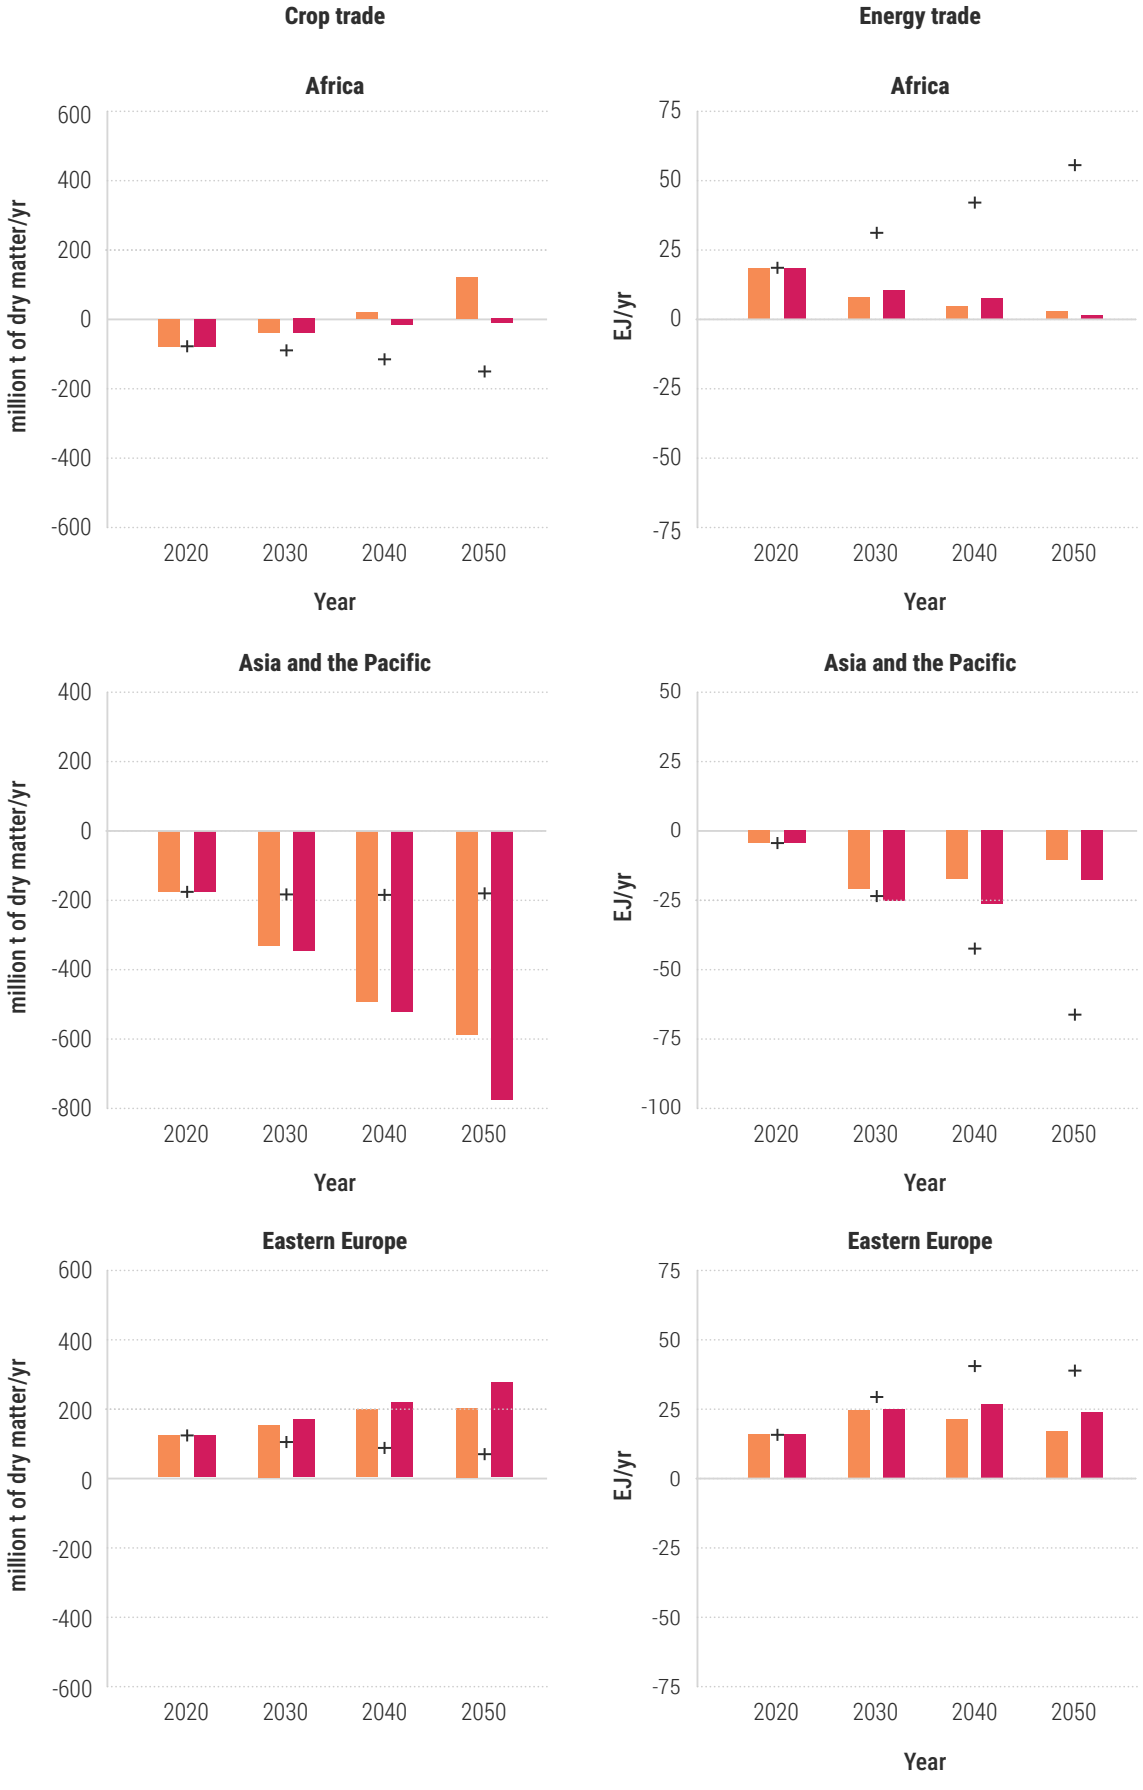
20.9 Changing Interrelationships Across Regions

The findings from all regions conclude categorically that remaining on the current path has negative and unsustainable implications for all the regions. Global goals and targets cannot be met leading to large economic and environmental implications.

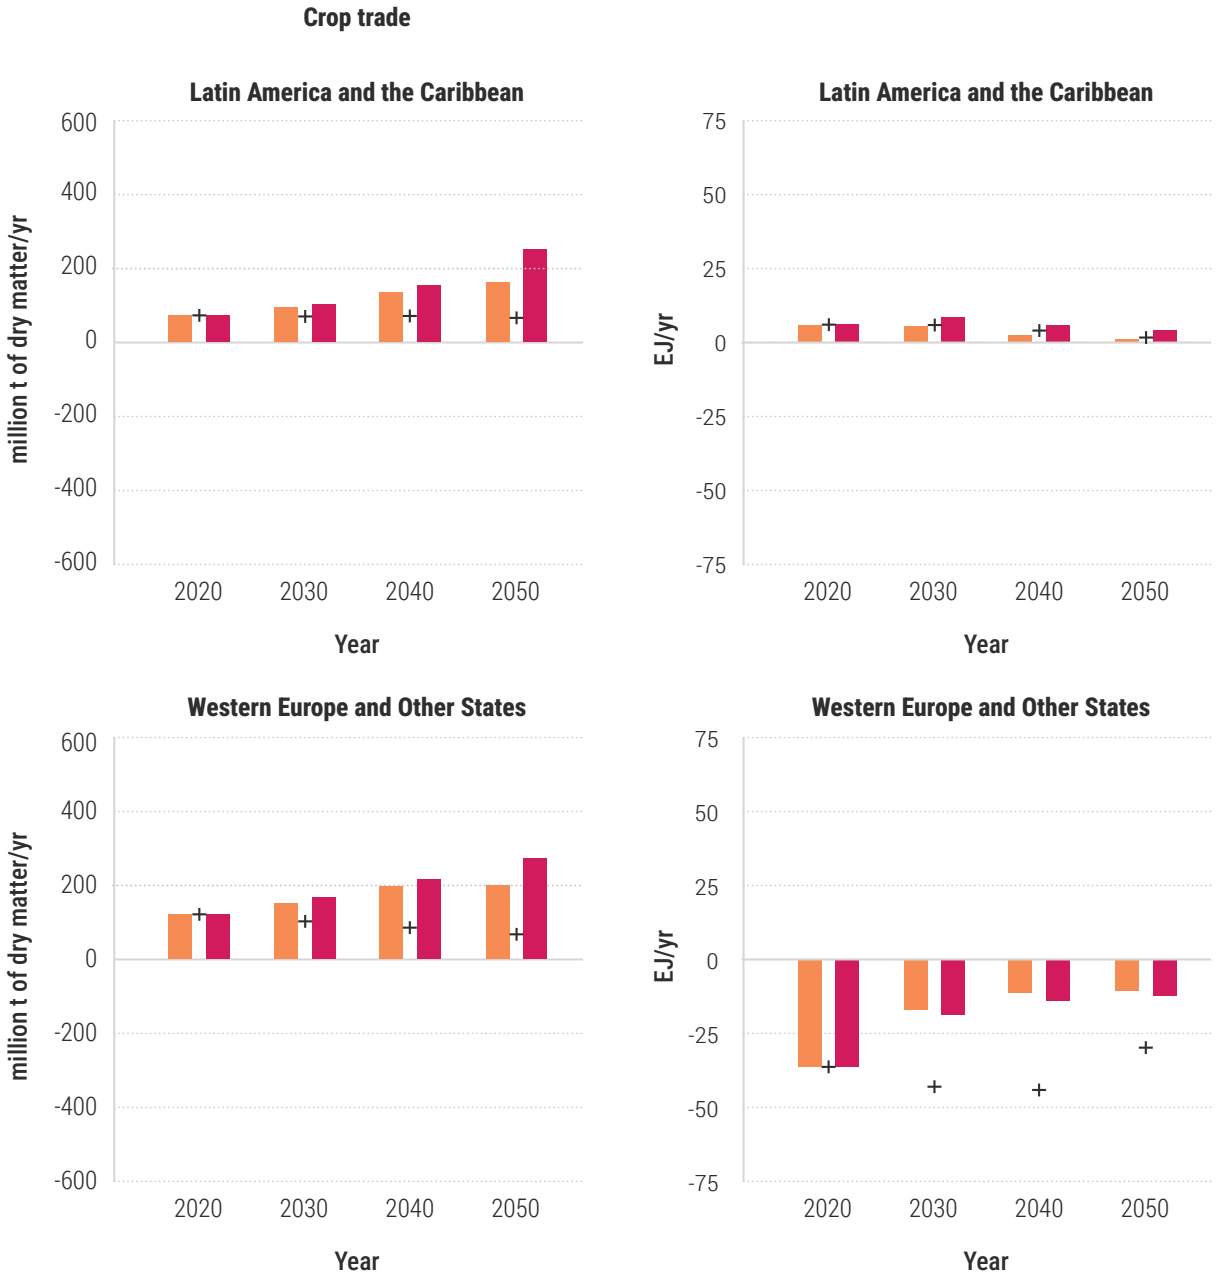
To build synergies based on interdependencies and shared relationships between and among different regions, there is a need for a coordinated and integrated economic and environmental systems transformation. This can be explored in the future using tele-coupling analysis. Understanding the future dynamics of tele-coupling is essential for developing effective solutions to global environmental crises.

20.9.1 Future tele-coupling dynamics and implications

Given the available simulation results from modelling the transformative pathways, our analysis builds on the state and trends tele-coupling introduced in Chapter 8, to explore the future potential of interregional dynamics through the trade of energy and crops (2020-2050). Simulation results, which group regions together, indicate that in the future, tele-coupling trajectories will vary substantially among regions, tele-coupling types, and over time under the pathways derived from all three Scenarios (**Figure 20.36**). Two specific types of tele-coupling dynamics were explored, namely energy and food, and their trade among the five regional groups.



There are often synergies or trade-offs among regions – such as when one region increases net exports while other regions decrease proportionally – with the subsequent tele-coupling types showing similar or opposite dynamics. The results shown in **Figure 20.36** demonstrate different patterns of crop and energy exports under different transformation pathways. Each region has a different trajectory occurring at different speeds.



These changing tele-coupling dynamics may reshape the geographic distribution of environmental-socioeconomic impacts and have substantial implications for the global environmental crises. Increasing net exports requires more production and may increase biodiversity loss, pollution, CO_2 emissions, and land degradation in the production and exporting regions. Specifically, there may be elevated adverse effects in EE, LAC, and WEOG, due to increasing crop production and net exports under the behaviour-focused transformation and the technology-focused transformation. For Africa, this occurs with a behaviour-focused transformation only in 2040-2050. For energy crops, Africa, EE and LAC continue to export in the future, albeit at a reduced rate, depending on the different behavioural or technology-focused actions that are introduced. However, for all scenarios AP and WEOG continue to import energy.

In other words, AP may be the only region with continuously declining impacts because of continuously increasing net crop imports. The effects of increasing crop production in and export from Africa may be partially offset by its declining energy net exports. Consuming crops requires energy, thus emitting more CO_2 in the countries where they are consumed. Consuming energy for other purposes also emits CO_2 although different types of fossil fuel and other biomass energy sources emit different amounts of CO_2.

Furthermore, production, consumption, and associated transport of energy and crops generate various

Figure 20.36: **Projected dynamics of telecoupling in crop and energy trades under current trends, behavioural-focused transformation and technology-focused transformation**

consequences for spillover regions – regions affected by the interactions within and between sending and receiving regions. To minimize trade-offs under the transformative pathways, it is crucial to develop new policies and new transformative pathways to enhance synergies among different regions for global sustainability.

20.9.1.1 Future regional dynamics

Analysing the differences that can be observed across regions in each of the assessed systems highlights that under transformative pathways there are likely to be new transboundary, cross-border and interdependent relationships between and among regions and subregions in the future. How might interdependency and shared relationships build synergy in the future?

Energy: In both pathways all regions globally show an increasing trend in renewable energy production in the total energy mix. In Africa and Asia and the Pacific regions there is a steady and sustained increase in energy demand driven by both population growth and increasing access to renewable energy technology. This is different than other regions where trends are slow. In the future, if a behaviour-focused pathway alone is followed, all regions experience less energy

demand than if adopting the technology-focused pathway. Renewable energy is driven by a mix of wind, solar and biomass with associated carbon capture system technology. This has implications particularly in Africa and LAC, where agriculture land is being used for biofuel production creating food security issues. A more balanced approach is suggested by the Global Bioenergy Partnership in the Asia and the Pacific as it has a large potential for both solar and wind (including in the Pacific islands) energy. In the WEOG region fast-track measures to transition away from fossil fuels towards renewables are possible and can be supported by appropriate policy actions.

Food: Differential patterns are observed across the regions resulting from changes to the food system in the future. Both the Africa and LAC regions see a significant increase in land-use demands to support dietary shifts alongside the increase of energy crops, which is different than other regions. For example, Eastern Europe could support a move from livestock towards more energy crops. Again, WEOG clearly has a strong potential to transition to climate-resilient agriculture and a change in diet through behavioural changes making a significant positive contribution globally to a sustainable future.

Material: There are strong synergies across all the regions for this system transformation. This will require consistency across subregions and regions. Successful circularity can create green jobs and improve livelihood. However, there is a need for comprehensive and systematic disciplinary frameworks for future strategic planning and technological advancements in the field.

Economic and financial: The WEOG region is well placed to lead change in transforming financial systems to support transformation in the energy, food, and material-waste systems. Consequently, there is a clear imperative for this region to move swiftly for a sustainable future. Across all regions there is evidence that market-based mechanisms such as carbon emission trading and pricing can support sustainable transitions. All regions point to the need of strong and sustained political will to underwrite the transition to a green and sustainable future.

Environmental: Africa and Latin America and the Caribbean experience worsening biodiversity, water quality and increased water abstraction in the future. By employing behavioural change actions across the systems, water can be more optimally used in those regions. Conversely, across Asia and the Pacific, improvements to air quality are clear in both pathways as a result of the move away from fossil fuels. Across all regions the implications for the environment from the behaviour-focused pathway are much lower than the technology-focused pathway. This consistent message suggests that any future change should be led by behavioural change measures complimented by suitable technologies where needed, to nudge the globe towards sustainability and resiliency to avoid unintended consequences.

20.9.1.2 How are the socioeconomic effects distributed differently?

It is clear that, in all the five regions future transformation must address poverty, hunger alleviation and inequality at their heart. In achieving transformational change in Africa, the co-benefits of emission reduction include higher living standards, poverty reduction and positive health outcomes alongside higher GDP.

In Africa and Eastern Europe as part of the transformation, subregional differences in inequity remain. These inequities exist in WEOG too, due to higher upfront costs for citizens to drive change. LAC highlight the potential for job losses through technological transformation which could be mitigated through robust reskilling education. Such systemic challenges and vulnerabilities can drive migration choices. However, across all regions a general trend towards positive economic and health outcomes are noted under both transformational pathways. All regions, however, suggest that a combination of actions drawn from both pathways will be required to steer society to a positive and equitable future.

20.9.1.2.1 How does policy implementation in one region affect another?

Driving global energy production change with technological transitions can result in increasing pressure on land in both Africa and the LAC region to support energy crops for biofuel with CCS options for a net-zero transition. Similar pressures are felt in these regions because of a global push towards plant-based diets. In these transitions it is important to recognize that the result of global action could lead to regional pressures. Similarly, the telecoupling

section highlighted other challenges across regions due to changing trade relationships.

How can countries capitalize or counter effects: In the system transformation processes, the countries are likely to experience trade-offs, for example between biodiversity conservation and economic development or between clean energy transition and economic growth. However, there are examples where synergy building achieves such massive ecosystem restoration, afforestation and reforestation, green jobs can be created, and microeconomic activities can be expanded to maintain economic growth and social well-being. Such opportunities must be explored to develop global transformation, while recognizing that the transitions are specific to their region.

20.10 Conclusion

To effectively address the global environmental crises, the world can adopt deliberate, radical and tailored transformative pathways (IPBES 2025). Both the direct and the underlying drivers of existential challenges can be addressed holistically, maximizing synergies and minimizing trade-offs. Specific policies that seem to work are whole-of-government and whole-of-society approaches (Ortenzi et al. 2022). Negative synergistic interactions of these crises can be addressed by multipurpose transformative actions (Lawrence et al. 2023; IPBES 2025).

Achieving global goals and targets is possible by halting overexploitation of natural capital and gradually eliminating unsustainable practices such as overconsumption and food waste by implementing circularity principles in waste management. However, for these changes to occur, necessary and urgent economic and financial system reforms will be needed that reflect enabling policies and regulations. Therefore, effective implementation of hybrid transformative pathways, combining regionally specific solutions from both, can lead to a rapid transition towards a resilient development paradigm (IPBES 2024).

The findings therefore conclude that a combination of technological applications and behavioural solutions can help countries achieve the necessary transformations across all systems. Since there will be systemic feedback loops between and among different systems such as food-energy-waste interactions, countries should aim to reform those system structures and processes that create barriers or negative feedback loops (UNCCD 2024). In particular, the financial and economic system transformation has the power to incentivize integrative and transformative actions leading to changes in all systems. Thus, financial system reform is a priority in all regions. Improving and strengthening the role of institutional and governance mechanisms in facilitating system transformation is required to support these transitions (Tomalka et al. 2024).

Appendix 20.1 A Eastern Europe Key Trends Across the 2030-2040-2050 Milestones

1. Milestone 2030: Early Phase of Transition

- Technology-focused Transformation Pathway:

  a. Energy and Infrastructure: The focus is on scaling up technological solutions, including large-scale renewable energy projects, combating energy poverty and initial deployment of carbon capture and storage (CCS) technologies. The energy grid begins modernization to accommodate higher shares of renewables.

  b. Economic Growth: The globalized economy model emphasizes efficiency gains, digitalization, and urbanization. The region experiences increased investment in high-tech industries, particularly in manufacturing and digital infrastructure.

  c. Environmental Systems: Early improvements are seen in emission reductions and energy efficiency, but biodiversity loss continues at a slower pace. There is a greater focus on industrial efficiency rather than ecosystem health.

- Behaviour-focused Transformation Pathway:

  d. Behavioural and Lifestyle Changes: Early stages of promoting sustainable consumption patterns, plant-based diets, and low-impact living. Decentralized energy solutions begin gaining traction, particularly in rural communities.

  e. Local Economies: Community-driven projects, agroecology, and green job creation become more prevalent. Regional economies prioritize inclusivity and resilience, focusing on reducing socioeconomic disparities.

  f. Environmental Systems: Efforts begin in earnest to restore ecosystems and integrate biodiversity into land management. Initiatives like rewilding and regenerative agriculture take root, enhancing climate resilience and soil health.

Policy Implications for 2030:

- Governments should prioritize investments in both large-scale infrastructure projects as Technology-focused Transformation Pathways and community-driven sustainability initiatives as Behaviour-focused Transformation Pathways. Early policy alignment is critical to ensure that the benefits of high-tech solutions reach all communities while fostering inclusive, sustainable growth.

- Strengthening cross-border energy cooperation and initiating region-wide environmental restoration projects will lay the foundation for future resilience.

2. Milestone 2040: Mid-Transition Phase

- Technology-focused Transformation Pathway:

  g. Energy Systems: Significant progress is made in just energy transition – including energy poverty, decarbonization, with a majority share of energy coming from renewables. CCS technologies are fully operational in key sectors, helping manage emissions from heavy industry.

  h. Economic Disparities: While urban centres benefit from economic growth, rural areas face challenges from automation and the shift to high-tech industries. Regional disparities may widen if adequate support mechanisms are not in place.

  i. Environmental Impacts: Although emissions are reduced, there are potential trade-offs as large infrastructure projects could impact local ecosystems and land use.

- Behaviour-focused Transformation Pathway:

  j. Resilience and Adaptation: By 2040, lifestyle changes are deeply integrated into

society, leading to lower energy demand, more sustainable food systems, and greater regional self-sufficiency. Circular economy practices gain momentum, focusing on waste reduction, repair, and resource efficiency.

k. Social Cohesion: The behaviour-focused pathway's emphasis on local economies, community resilience, and shared resources ensures more equitable distribution of benefits. Green jobs in sectors like agroecology, sustainable forestry, and decentralized energy aiming also at combating energy poverty are widely available.

l. Environmental Benefits: Biodiversity and ecosystem health are notably improved, with widespread adoption of sustainable land management practices including organic certification. Nature-based solutions complement technological advances, enhancing regional climate adaptation.

Policy Implications for 2040:

- To manage disparities, poverty energy, governments need to implement robust just transition frameworks that bridge the gap between urban and rural areas. Policies should support upskilling and job creation in green sectors, ensuring that economic benefits are shared across regions.

- Integrated environmental strategies should align high-tech solutions (e.g., precision farming) with nature-based approaches like reforestation to maximize co-benefits in climate, nature, and pollution control.

3. Milestone 2050: Achieving Sustainability Goals

- Technology-focused Transformation Pathway:

m. Full Decarbonization: The energy system is nearly fully decarbonized, with renewables, smart grids, and CCS technologies playing central roles. Electrification of transport and industry is widespread, leading to significant reductions in greenhouse gas emission

n. Globalized Economy and Urbanization: The region's economies are highly integrated into global supply chains, with productivity gains driven by automation and digital technologies. However, social inequalities could persist if technological advancements are not accompanied by equitable access and social protections.

o. Environmental Sustainability: While emissions are under control, large-scale industrial activity may still pose challenges to biodiversity and resource management if not carefully managed.

- Behaviour-focused Transformation Pathway:

p. Low-Impact Lifestyles: By 2050, Eastern Europe has largely adopted circular economy principles, leading to minimal waste generation, high resource efficiency, and widespread sustainable consumption. Communities are self-reliant, with strong local economies based on low-impact practices.

q. Holistic Environmental Health: The behaviour-focused pathway achieves long-term environmental resilience through extensive rewilding, protected areas, and regenerative practices. Ecosystems are restored, contributing to climate stability, clean water, and healthy soils.

r. Social Equity and Well-being: The emphasis on inclusivity and community resilience results in high levels of social cohesion, health, and well-being. Poverty and inequality are minimized as green jobs, local ownership, and community-based solutions take centre stage.

Policy Implications for 2050:

- Governments should focus on sustaining and scaling up successful initiatives from both pathways. Policies should ensure that technological advancements remain accessible

to all while supporting decentralized and community-driven models that promote equity and resilience.

- Long-term governance frameworks must prioritize ecological restoration, cross-border environmental cooperation, and alignment between economic activities and planetary boundaries.

Conclusion: Key Trends and Strategic Recommendations for 2030-2040-2050

The three milestones highlight the evolving needs and opportunities as Eastern Europe progresses through its sustainability transition. By integrating the technology-focused pathway's high-tech efficiency with the behaviour-focused pathway's inclusive and low-impact approaches, governments can achieve a balanced strategy that delivers socioeconomic benefits while ensuring environmental sustainability.

Strategic Recommendations:

Hybrid Governance Models: Adopt policies that balance large-scale infrastructure investments with localized, community-driven solutions. Regional cooperation and policy harmonization will be critical to achieving shared goals.

Inclusive Growth Strategies: Support the creation of green jobs and equitable access to the benefits of technology, particularly in rural and marginalized areas. Just transition policies including within the area of combating energy poverty – an area of real concern for Eastern Europe, are essential to prevent widening disparities.

Environmental Integration: Align technological innovations with nature-based solutions, ensuring that climate, nature, and pollution goals are addressed holistically. Cross-border environmental projects should be a priority to maximize regional resilience.

Long-Term Resilience: Plan for resilience by investing in decentralized energy systems, sustainable agriculture, and regenerative land-use practices. These investments will ensure that the region can thrive even as global challenges evolve.

This comprehensive approach enables Eastern Europe to navigate the complexities of the 2030-2050 time frame, positioning the region as a leader in sustainable development while addressing the needs of all communities.

Chapter summary

Credit: Naypongstudio/Envato

Achieving internationally agreed environmental, social and economic goals requires whole-of-government and whole-of-society approaches (*established but incomplete*). These approaches can transform interconnected economic and financial, energy, food systems, materials/waste and environmental systems. Such a transformation, in turn, requires identifying and implementing solutions that leverage synergies, such as nature-based solutions, while limiting trade-offs, such as job losses, across systems. These approaches also necessitate putting circular economy principles into practice; changing entrenched values and behaviours; accounting for diverse worldviews and knowledge systems; committing to just and equitable principles; facilitating co-production in scenario modelling; and strengthening capacities to manage increasingly ambitious multidimensional changes {21.5}.

A whole-of-government approach necessitates breaking down silos and engage in new forms of multilateralism (*established but incomplete*). Internationally agreed goals require aligning national policies with international goals while recognizing that no single ministry or department can transform the economics and finance, energy, materials, environment and food systems alone. Inter-agency committees, staffing rotations, innovative cross-agency budgeting practices and harmonized reporting protocols can help forge these connections. Though shifting power dynamics, rising nationalism and institutional weaknesses threaten international cooperation, new forms of multilateralism that capitalize on adaptive, forward-looking policies and build bridges across diverse national and subnational interests offer a way forward {21.5}.

A whole-of-society approach requires enabling the meaningful participation of all agents of change (*unresolved*). It is essential that governance reforms promote the inclusion of all agents of change to achieve sustainable solutions and just transitions. Boosting accountability, transparency and addressing the underlying causes of unsustainability are also critical. The growing role of actors beyond government, such as corporations, financial institutions, labour groups, civil society and local communities can contribute to positive outcomes

Table 21.1: Actor categories and their roles

Actors	Roles
Governments	Establish policies, legislation, and financing. Transform economic, financial, energy and agricultural systems, repurpose subsidies, internalize externalities, and develop policies and technologies to reduce GHG emissions, improve energy efficiency, minimize food loss and waste, enhance climate resilience in food and water systems, and integrate natural capital in decision-making.
Intergovernmental organizations	Coordinate efforts, set global standards, and finance global public goods, such as a stable climate. Support economic and financial transformation through policy guidance and risk monitoring; advance energy transformation by promoting renewable energy and clean technology; and promote climate-resilient agriculture.
The public	Consumers, voters, workers, investors, activists, and community members. Drive system transformation by, for example, supporting green businesses, ethical finance, and greater local resilience in energy and food systems.
Civil society	Connect people to power, hold institutions accountable and advocate for justice, sustainability and inclusivity. Transforms systems through advocacy, public awareness and expose corruption and harmful practices.
Private sector	Align profit with purpose, makes market goods and invests. Transform the economic and financial system by channelling investment in green products; shifting away from fossil fuels in the energy system; and committing to fair trade, no deforestation and ethical labour in supply chains.
Academia	Generate knowledge, educate leaders and shapes policy and innovation. Transforms all systems by training future leaders, informing policy with independent research, and advancing the development of clean technology, biotechnology, and data science.
Nature	Provide resources and shapes the stability, productivity and sustainability of systems. Drive system transformation by promoting natural capital approaches, supporting renewables, sustaining agriculture through ecosystem services, and regulating climate, carbon, airsheds, and water systems. Nature is foundational to the long-term sustainability of all human and ecological systems.

across contexts, scales and sectors. Their participation must be embedded within governance systems to ensure sustainable transformation and effective implementation {21.5}.

Unpacking the roles and actions of agents of change – individual actors, networks of actors, and communities of interest and social movements – can help accelerate transformation (*well-established*). Actors refer to governments, intergovernmental organizations, the public, civil society, the private sector, academia, professional organizations, and nature. Networks of actors include the UN regions, the EU, and cities. Communities of interest refer to spiritual and faith groups, Indigenous Peoples as well as local communities that coalesce around common interests or values, and social movements that work together to shift dominant societal practices, such as climate, youth, or educational movements. This categorization suggests actors can be human or non-human, individual or collective, formal or informal, material or immaterial {21.41} (Table 21.1)..

Networks of actors: Clubs of like-minded countries and actor constellations offer promising avenues for plurilateral cooperation, enabling solutions by reducing gridlock and facilitating joint action. One example is the Coalition of the Willing on Pollinators, with over 32 countries and four observers, including the United Nation's Food and Agriculture Organization and Biodiversity and Ecosystem Services Network, promoting country-led policy and innovative action to protect pollinators. Another example is the Covenant of Mayors, a political network of urban leaders committed to climate and energy action {21.4.9}.

Communities of interest and social movements: Actors and networks united by shared values – such as religious beliefs, environmental protection, and rights – form a collective force for change. They

transcend geography and individual interests to influence decisions and drive system transformation. Examples include slow-food communities, food councils, India's Chipko and Niyamgiri movements, the Chico Mendes movement in Brazil, and Buen Vivir in Latin America {21.4.1.10}.

Nature is a powerful actor that deserves greater representation in decision-making processes (*established but incomplete*). Rooted in the understanding of life's interdependence, many Indigenous worldviews and legal systems see nature as intertwined with human systems, carrying mutual responsibilities. Nature should therefore not be treated as an externality, but as a foundational actor and provider of services whose health underpins the health of all human systems. This can be achieved through integrating ecological values, natural capital accounting, ecosystem-based approaches and prioritizing ecosystem health in system transformations {21.4}

Agents of change are often motivated to act in their self-interest in health and well-being, economic and financial stimuli, regulatory frameworks, and culture, imaginaries, norms, common values and beliefs (*established but incomplete*). Examples of how these motivators can stimulate action include the following:

- **Health:** a recognition that human and planetary health are interconnected, for example, concerns over a population's raising rates of obesity, diabetes and heart disease – all linked to poor diets, air pollution and sedentary lifestyles – can become the catalyst for transformative change by driving reforms to food, energy, urban, transport and other systems, even redefining economic prosperity {21.4.2.1}.

- **Economic and financial:** actions can be stimulated by economic incentives that make transformation profitable, or by a recognition that nature underpins the long-term sustainability of their business, for example, nature-positive economic and bioeconomy approaches {21.4.2.2}

- **Regulatory frameworks:** legislation and regulations that incentivize or penalize businesses can motivate action, for example, legislation that embodies the Polluter Pays Principle {21.4..2.3}.

- **Culture, imaginaries, norms, common values and beliefs**: these can motivate action by shaping perceptions, fostering identity and solidarity, and providing a moral compass to guide actions, for example, Indigenous leadership in sustainable land governance and biodiversity conservation {21.4.2.4}.

Changing power-interest dynamics to prevent vested interests from capturing environmental regulatory and related policymaking processes is essential (*well-established*). Prospects for transformation can be enhanced by understanding an agent's interest in and power over food security, energy access, social equity and related policy issues. In many countries, large multinational corporations possess the power and/or interest to prevent change, while NGOs and community-based organizations have the interest but not the power to promote change, and the public may lack both the interest and power to drive change. All agents of change must feel empowered and develop an interest in transformations. Empowering Indigenous Peoples, local communities, and other marginalized groups can alter inequitable power dynamics. Strengthening public integrity and accountability can accelerate sustainable transformations {21.4.1.11}.

Comprehensive packages of policy and enabling reforms are needed to break systemic lock-ins (*unresolved*). Breaking interrelated barriers and lock-ins across systems requires a mix of strategies – big plans, small wins and systemic rule changes. For example, phasing out coal, ending fossil-fuel subsidies, reskilling workers, and highlighting adverse health effects can make energy systems more sustainable. Reforming subsidies, ensuring fair market access, securing land rights, and shifting diets can transform food systems. These approaches can gain momentum during environmental crises, such as past pollution events that drove environmental reforms in the United States of America and China, and through deeper value shifts, such as embracing care, reciprocity, and rethinking human–nature relationships {21.5}.

Ultimately, strengthening global cooperation and adopting bold policies are essential for driving a transformation that is not only swift but also just

Credit: ©UNEP

and sustainable (*unresolved*). This is achievable but will require unprecedented action to address geopolitical tensions, stabilize the climate, restore ecosystems, build zero-waste economies, and ensure equity, and may require new forms of multilateralism that are more target-focused and agile. Countries at different development levels will need tailored approaches, with low-income countries focusing on technology and infrastructure to boost yields and cut energy use, while high-income countries prioritize decarbonization, electrification, sustainable diets, and food systems. Crucially, all actions must centre on the rights and resilience of the most marginalized to ensure a just and inclusive transformation {21.5}.

21.1 Introduction

The evidence is clear: resource-intensive development patterns have given rise to climate change, biodiversity loss, land degradation and desertification and pollution and waste crises. Chapters 3–6 covered these crises, demonstrating that they are attributable to human activity. Previous chapters also demonstrate that these crises are part of the reason the world is not on track to achieve the Sustainable Development Goals (SDGs), the Paris Agreement, or the 2050 Vision for Biodiversity (Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services [IPBES] 2019; United Nations 2023; Intergovernmental Panel on Climate Change [IPCC] 2023).

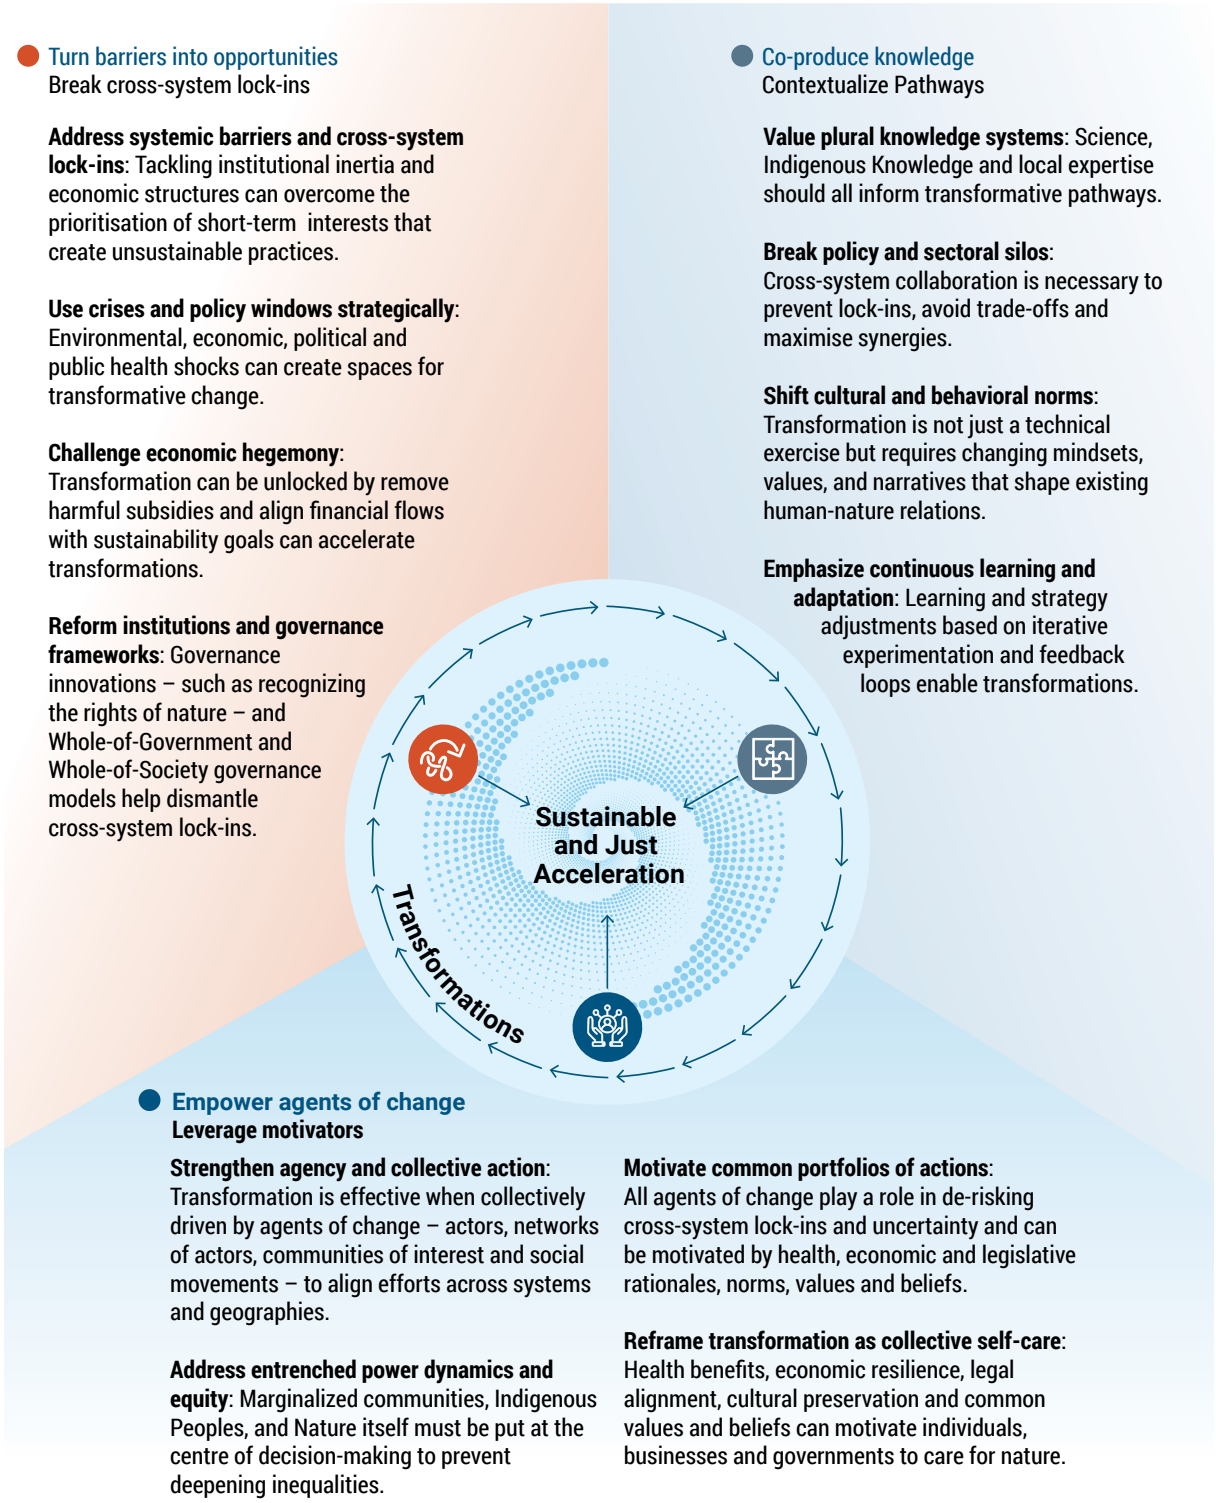
The evidence suggests the world is running out of time to live within planetary boundaries and maintain safe operating spaces (Rockström *et al.* 2009; Rockström *et al.* 2013; Gupta *et al.* 2024; van Vuuren *et al.* 2025). A course change is needed to alter the direction and character of development. Such a change requires working across scales, inducing deep shifts in values and behaviours, and engaging a diverse range of agents of change in a concerted effort to transform unsustainable systems. In short, existing transformations must be accelerated if we are to achieve internationally agreed targets. The focus on accelerating transformation builds on developments in previous chapters. Chapters 10–11 outline the global implications of continuing current trends and explore possible transformative pathways. Chapters 19 and 20 describe such pathways for different income groups and regions. Chapters 12 and 13 define six principles of transformation and outline seven steps to develop solution pathways in five systems, covered in Chapters 14–18.

While transformation is not new to this Global Environment Outlook, Chapter 21 is unique in that it aims to explain how a sustainable transformation can be accelerated. Much of the answer to the acceleration question lies in three processes (**Figure 21.1**). The first process involves enabling the participation of different agents of change in the co-production of transformative pathways. The second process consists of combining targeted interventions and promoting shifts in values and beliefs to break lock-ins that run across systems. The third process involves empowering agents of change to rebalance power-interest dynamics and form joined-up agendas that help drive forward the other two processes.

Although the chapter presents the three processes separately, they often overlap and feed into each other in practice. For instance, co-production involves engaging with different agents of change to break systemic lock-ins and open opportunities for leveraging motivators. These processes are also complex, non-linear and characterized by feedback loops and uncertainties, mirroring the broader political-economic context in which they operate. Hence, a discussion of governance arrangements that bring together the processes and agents of change as part of whole-of-government and whole-of-society approaches concludes the chapter.

21.2 Co-producing transformations across systems and regions

21.2.1 The scale and pace of change



This section begins with a brief review of modelling results on the scale and pace of change, setting the stage for discussion of the co-production process that can help contextualize key insights from the exercise. One of the most important insights from the modelling is that the world needs to dramatically increase the speed and scale of changes to achieve internationally agreed environmental goals. For instance, the modelling shows a need for significant increases in agricultural yields, decarbonization and electrification rates, energy intensity, and dietary shifts between 2020 and 2050. Results related to energy and food systems indicate similar trends.

However, the modelling also underlines options within and across systems and regions that can help make those changes possible. One way to accelerate this large-scale transformation is to capitalize on synergies across energy, food, and other systems. For instance, decarbonizing the energy system can reduce water use for cooling in thermal power plants. This, in turn, can reduce both energy demand and the amount of land used to grow bioenergy products. The spared land could be used for installing large-scale solar installations, while improving agricultural productivity, saving water and preserving biodiversity. Adaptation strategies that build resilience can also complement synergies among energy, food and other systems (**Box 21.1**).

Another way to accelerate transformation is to tailor pathways to countries and regions at different development levels, as shown in 19.6 with a discussion of different approaches to transforming food systems. To illustrate, the modelling shows that low-income countries would benefit from concentrating on technological and infrastructure investments that increase crop yields and reduce energy intensity. At the same time, high-income countries would benefit from focusing on decarbonization

Figure 21.1: How to accelerate a sustainable transformation

A sustainable and just acceleration for all requires systems to transform faster, and at a greater scale, and higher level of cross-system integration and depth.

and electrification, while reducing meat consumption and improving food system sustainability. These tailored approaches can also generate wide-ranging synergies not only across systems but also across regions. For example, decarbonization efforts in high-income countries can lead to positive technological changes, such as the development of more efficient solar panels, that spill over into other sectors and regions (Ndicu *et al.* 2023).

Box 21.1: Adaptation can strengthen integration and acceleration across systems

While transformative pathways require changes in energy and food systems, climate adaptation strategies could enhance resilience within these systems and strengthen synergies between them. For example, in the energy sector, adaptation measures might upgrade infrastructure to withstand extreme weather events while delivering additional benefits for food security. Meanwhile, climate adaptation in food systems can improve water use efficiency to cope with changing rainfall patterns, while also yielding additional energy savings (Nenkov 2024). Further, adaptation can facilitate transformative pathways by reducing risks associated with rapid changes – for instance, in low-income countries where agricultural productivity needs to increase significantly, adaptation measures could include developing early warning systems and crop insurance schemes. These systems could not only protect farmers from climate-related losses but would also help stabilize energy and food systems as they too undergo changes (Ivanova et al. 2020).

21.2.2 Co-producing pathways and sustainable futures

One of the keys to a synergistic and tailored approach to accelerating sustainable transformations is the co-production of pathways. Co-production is a process that enables the participation of diverse agents of change in the creation and application of context-specific, inclusive and plural solutions to complex challenges (Djenontin and Meadow 2018; Moallemi *et al.* 2023). These solutions combine different forms of local knowledge, including post-colonial, feminist and intersectional perspectives, with scientific expertise, including data-driven modelling (Djenontin and Meadow 2018), which can accelerate transformation by increasing the likelihood of acceptance and implementation across diverse communities and systems.

Co-production has several strengths that can facilitate the integration of these different forms of knowledge and ensure that pathways align with the needs of diverse agents of change. For instance, co-production can help build collective ownership while encouraging innovative thinking about sustainable solutions (Polk 2015). It can further forge different interests and place greater emphasis on the governance reforms that could help articulate those interests (Sorrentino, Sicilia and Howlett 2018). Co-production also allows for contestation, empowering marginalized voices that might otherwise be left out of decisions over pathways and futures (Scoones *et al.* 2020).

Many tools can facilitate participation in co-production processes, including foresight tools such as horizon scanning and scenario planning. These tools have proved useful in helping different agents of change consider emerging issues, and multiple outcomes and futures (United Nations Environment Programme [UNEP] and International Science Council [ISC] 2024). Some co-production tools have a less technical orientation; arts-based methods can contribute to modelling by creating inclusive spaces for dialogue and collaboration, encouraging plurality and catalysing new ways of approaching sustainability (Heras *et al.* 2021; van Beek 2025). Importantly, these approaches can transcend hegemonies by creating new imaginary worlds through artistic and experiential methods that enable participants to reflect on sustainable futures (Bendor *et al.* 2017) and inspire local transformations (Bentz *et al.* 2022).

It is nonetheless important to recognize that co-production has limitations and can slow down acceleration. For instance, co-production is often dominated by depoliticized discourses that employ scientific arguments to evoke universalized ideas (Turnhout *et al.* 2020, p. 16). In these cases, scientific knowledge can be ascribed a stronger authority compared to other knowledge systems, including Indigenous ones, due to colonial modernities (Arora and Stirling 2023). Co-production can also be both a knowledge-making and political practice, which can fail without sufficient attention to power imbalances and political structures (Turnhout *et al.* 2020; Chambers *et al.* 2022). Because equality among participants is not guaranteed, elite participants can use their resources to manipulate processes to advance their own interests.

Making co-production sustainable and inclusive requires efforts to recognize and work around these limitations. This can entail ensuring that co-production is intentional and embraces pluralism in the production of knowledge. It can also involve amplifying marginalized perspectives so that they can challenge existing hegemonic perspectives and formations (Scoones *et al.* 2020; Hamilton and

Ramcilovic-Suominen 2022; UNEP and ISC 2024). Finally, co-production can be guided by ethics of care (UNEP and ISC 2024) and include representations of nature in decision-making (Puig de la Bellacasa 2017), drawing on relational philosophies and practices that are familiar to different Indigenous Peoples (**Box 21.2**). These approaches can ensure co-production helps to contextualize transformative pathways and futures, speeding up the pace of transformation.

21.3 Overcoming barriers and breaking lock-ins

This section focuses on two key challenges in transforming systems: system-level barriers and cross-system or systemic lock-ins. It begins by organizing barriers at the system level and progresses to breaking the lock-ins that form across systems due to the interconnections between them.

21.3.1 Identifying and organizing barriers

Barriers are deeply embedded obstacles that prevent change in key systems and reinforce status quo decisions and development patterns. While there are many ways to classify barriers, this section organizes them into economic and financial, social, environmental, institutional or political, and technical categories. This classification is helpful as barriers tend to be context- and system-specific (**Table 21.2**). Their specificity makes it relatively straightforward to determine ways in which they can be overcome.

While it can seem relatively straightforward to remove a barrier on paper, it is important to recognize the underlying reasons barriers exist. These range from sunk costs in existing infrastructure to institutional processes embedded in laws, policies, and bureaucracy to established markets with high entry costs. Other sources include easy access to capital for business-as-usual investments and elites that control resources and power. Yet another set of reasons for barriers are environmental values favouring established practices, irreversible biophysical changes such as land use, knowledge shaped by inequalities and hegemonic perspectives, and established consumptionpatterns (Goldstein *et al.* 2023).

21.3.2 Cross-cutting lock-ins

Lock-ins are systemic inertias that arise from mutually reinforcing collections of barriers that make their combined effects greater than the sum of their individual parts (Elliot 2011; Stoddard *et al.* 2021). These combinations can lead to self-reinforcing dynamics that promote overconsumption, perpetuate inequities, and prioritize profits over

Box 21.2: Aspects of desired futures according to Indigenous Peoples

- Spiritual reconnection and respect for the values of "good living" as embodied in concepts of care, for example, Sumak Kawsay of the Quechua Peoples.
- Territories of life cared for and managed by Indigenous communities and guided by Indigenous Knowledge, organization, and spirituality, and recognizing Indigenous human rights.
- Strengthening food sovereignty based on the rescue of traditional agriculture and fishing, and the promotion of agroecological practices.
- Sustainable, social and solidarity economy, not the exploitation and commodification of natural resources.
- Financing and accountability whereby Indigenous Peoples can manage funds, and enhanced accountability for the effects of funding extractive and polluting practices.
- Generating climate forecasts with farmers, pastoralists and national meteorological systems through on-farm rainfall data production through stakeholder engagement processes.

Sources: UNEP and ISC (2024, p. 34-37) and Figure 2.2, IK&LK Chapeau D.

Table 21.2: Illustrative examples of different types of barriers across the five key systems

Barriers	Economic System	Materials/waste System	Energy System
Economic and financial	• Resource-intensive development models • Pricing structures that fail to internalize externalities • Subsidies for unsustainable products/practices • Limited access to green financing	• Market dominance of virgin materials • Low costs of single use products • Fragmented supply chains • Trade barriers to recyclable materials	• High initial costs – sometimes perceived – of low carbon technologies • Fossil fuel subsidies • Lack of finance for energy efficiency • Grid connection costs • Energy dependency • Monopoly of large-scale energy providers
Social	• Cultural norms of overconsumption • Workforce skill gaps • Short-term thinking • Social stigmas around alternative economies • Economic inequality and injustice • Promotion of extraction and exploitation of nature	• Lack of awareness and education of lifecycle effects • Consumer preference for new products • Norms around disposability and recycle-reuse-repair • Social stigma around alternatives modes of production and consumption.	• Perceived high costs of renewable energy • Not in my backyard (NIMBY) • Lack of customer demand for low-carbon energy • Energy poverty and inequality • Identity issues
Environmental	• Land and resource scarcity • Unaccounted environmental risks and costs • Environmental externalities	• Inefficient recycling systems • Natural resources depletion • Poor waste-to-energy practice • Microplastics	• Water use and pollution • Environmental impact of mining • E-waste from renewable-energy technologies
Institutional or political	• Corruption and lack of transparency • Political polarization • Institutional inertia and silos • Limited institutional capacity • Regulations and legislation that support unsustainable practices	• Lack of regulations and legislation • Waste management systems • Lack of institutional collaboration • Lack ofCorruption and lack of transparency • Political polarization • Institutional inertia and silos • Limited institutional capacity • Regulations and legislation that support unsustainable practices multi-level multi-scale coordination	• Fossil fuels' political and lobbying groups • Centralized large-scale energy providers • Energy market structure/ governance
Technical	• Outdated infrastructure • Lack of skills • Dependence on foreign markets and access to markets • Weak digital economy	• Materials contamination • Availability of close-loop systems • Limited technology and processes for material disassembly/ recovery/ upcycling/ reuse/ remanufacturing	• Intermittency of renewable energy • Availability of energy-storage technologies • Energy conversion efficiency and transmission losses • Grid capacity

Barriers	Food System	Environmental System	Cross-cutting
Economic and financial	• High costs of sustainable foods • Subsidies for industrial agriculture • Cost of land and water • Import dependency • Limited demand for organic or sustainable produce	• High costs/lack of investment in pollution-control technologies • Short-term economic priorities • Lack of investment in conservation • Profit-driven resource exploitation. • The true cost of our production systems and their products	• Dominance of anthropocentric worldviews • Growth-oriented development • Market competition and short-termism • Inequality • Vested interests, regulatory capture and corporate controls • Lack of policy integration • Lack of whole-of-government and whole-of-society governance models • Unsustainable habits, behaviours and social norms • Resistance to change • Lack of awareness and education • Lack of whole-of-government and whole-of-society governance models • Unsustainable habits, behaviours and social norms • Resistance to change • Lack of awareness and education
Social	• Cultural food preferences • Food deserts • Food insecurity • Resistance to change in diets and food habits • Limited awareness of environmental impacts of dietary choices • Unhealthy food behaviours	• Attitudes towards nature and human-nature relationships • Environmental inequality and injustice • Limited acceptance of pollution control technologies and clean fuels. • Perceptions of environmentalism as a luxury	
Environmental	• Water scarcity • Soil degradation • Use of fertilizers and pesticides • Match between crops and climate	• Geography • Climate conditions • Climate change • Invasive species • Deforestation	
Institutional or political	• Dominance/ influence of market/ corporate forces • Globalized food chains • Agricultural policy • Lack of support for small farmers/ agroecological practices	• Lobbying by polluting industries • Lack of environmental legislation and regulation • Prioritizing development over conservation • Lack of political will for climate action • Climate deniers	
Technical	• Crop yields • Irrigation systems • Pest and disease control • Outdated farming technology/ infrastructure • Food processing/ storing/ transportation technology	• Availability of pollution control and clean technologies • Lack of biodiversity/ climate change monitoring models/ tools • Water purification/ desalinization technology	

people (Béné 2022; Beery *et al*. 2023). Such dynamics are partially attributable to the fact that lock-ins tend to work across systems (Seto *et al*. 2016; Unruh 2000; Unruh 2002).

For example, a carbon lock-in occurs when centralized fossil-fuel energy systems create self-reinforcing inertia, hindering alternative technologies. This is driven by economic and policy disincentives, public acceptance, and energy-dependent lifestyles (Rydin and Turcu 2019; Goldstein *et al.* 2023). It can also be driven by high sunk costs and long capital lifetimes that can, for instance, make it challenging to decommission coal-fired power plants. Such lock-ins can occur in cities where structural political and economic drivers reinforce unequal and environmentallyunsustainable development practices. Additionally, business-as-usual urban planning and complex urban governance networks further entrench thesebarriers (UNEP and UN-Habitat 2021, p. 26).

Food systems are locked into industrial farming by multinational corporations, driven by high-yield monocultures, intensive use of chemicals and large-scale mechanization (Béné 2022). High-tech farming is seen as the key to success, discouraging sustainable practices due to economic and social barriers. Global factors such as corporate dominance, financial markets, deregulation, privatization, and austerity further channel capital into unsustainable commodity agriculture, making food systems less sustainable and healthy.

Similar lock-ins can be found in the forestry sector, where commodity-driven deforestation is fuelled by institutional and corporate interests, disproportionately affecting lower-income regions. At the same time, high-income countries drive demand for products like palm oil and cocoa (Santika *et al.* 2023). Corporate zero-deforestation pledges face economic and institutional barriers, including low market adoption, loopholes, weak compliance, and limited scope, yielding minimal results (Lambin and Furomo 2023). Modest progress has been made with region- and commodity-specific zero-deforestation commitments, but scaling requires broader corporate adoption and market coverage (Lambin and Furumo 2023).

Lock-ins are mostly problematic because they interact across systems, such as those involving energy, food, and materials/waste. Such cross-system lock-in occurs in industrial agriculture, which relies on fossil-fuel-based fertilizers, mechanization and global supply chains. This dependence reinforces high energy consumption and waste generation, while limiting the adoption of regenerative farming, local food systems, and circular practices such as composting and bioenergy production. Interconnected lock-ins perpetuate resource inefficiencies and environmental degradation and pose significant challenges for resource management and sustainable development (Horlings 2018). They can lead to stranded assets, where abandoned infrastructure investments cause environmental harm in countries unable to afford transformation (Heras and Gupta 2023).

21.3.3 Overcoming multiple barriers to break cross-system lock-ins

To drive transformation, systemic lock-ins must be understood and turned into opportunities, with interventions focused on removing specific barriers or system-specific lock-ins that reinforce each other. Interventions may include reducing initial investment costs or removing harmful subsidies to address economic barriers. Social barriers can be tackled through programmes that raise public awareness and promote the public acceptability of sustainable alternatives. Legal reforms aimed at enhancing transparency in budgeting and contracting can help reduce corruption and overcome institutional or political barriers. Advances in data and management technologies may also remove barriers to creating pathways for sustainable change (**Box 21.3**).

The most effective approach is often when multiple interventions are combined to build public support for reforms. For example, the city of Rosario in Argentina successfully navigated systemic lock-ins by fostering democratic decision-making over resources at the district level. The Rosario Habitat programme improved informal settlements, living standards, and tenure security, while the Rosario Urban Agriculture programme integrated urban farming into land-use planning and enabled participatory budgeting to redistribute resources and strengthen community capacity building (UNEP and UN Habitat 2021, p. 177).

Cities can utilize various entry points to transform system-level barriers into opportunities and overcome

Box 21.3: Data, barriers and lock-ins

Transformative change relies on access to, management of, and analysis of high-quality environmental data. From in situ measurements to satellite remote sensing, this data forms the foundation for informed decisions (ITU News Magazine 2020). Advances in artificial intelligence, machine learning, and big data can also help overcome these barriers (Duporge et al. 2021; Robinson et al. 2021). Open data access, open science, citizen science (Landman et al. 2020; Nyadzi et al. 2022; Nkuba et al. 2023), and scientific diplomacy can help extract and share the data necessary for sustainable transformation. Key questions moving forward include how to clear barriers to data sharing and how technological and social changes, such as big data and citizen science, can make more data accessible to accelerate transformations.

cross-system lock-ins. In some Latin American and African cities, vulnerable communities have improved their quality of life by recycling waste while promoting circularity. Local governments have played a key role by providing legal frameworks, economic support, and formalizing these efforts. Some argue that these local urban initiatives – in Bogotá, Buenos Aires, Lima, Quito, São Paulo or Durban – can be scaled by aligning with international processes such as the 2030 Agenda (de Miguel *et al.* 2021).

In the food and agriculture sector, several strategies are employed to promote sustainable agriculture, including land care in Australia, community forest management in India, Nepal, and Viet Nam, and farmer field schools and irrigation user groups in Asia, Africa, and Latin America (Pretty *et al.* 2018). A transformative policy-led redesign of agrifood systems is underway in Andhra Pradesh, India (Bharucha, Mitjans, and Pretty 2020). Similarly, agroecology movements in Brazil show how to create collective spaces for sustainable food alternatives that extend beyond the local scale (van den Bergh *et al.* 2022). Scientific evidence shows that clear, ambitious policies, adequate financing, institutional support, and multi-faceted capacity building can reduce farmers' costs, increase yields, improve farm health with locally sourced inputs, and provide additional co-benefits, making the transformation of the food system more feasible (Bharucha, Mitjans, and Pretty 2020).

Efforts to turn barriers into opportunities should not only focus on new approaches. Many agroecological transformations are supported by Indigenous Peoples who have practised sustainable farming for generations (UNEP and ISC 2024) – Mayan communities in Central America use traditional milpa agroecological and spiritual farming systems that enhance ecosystems (Pretty *et al.* 2018; Bharucha, Mitjans, and Pretty 2020; UNEP and ISC 2024). Other examples demonstrate that recovering and expanding Indigenous foodways – rooted in autonomy, self-determination, care, spirituality, and justice – can support sustainable agroecological practices (Huambachano 2024; Nkuba *et al.* 2021; Nkuba *et al.* 2023).

In some cases, combining science and traditional practices can clear barriers. For example, in the Appalachian Mountains, integrating scientific and local knowledge showed that ancestral apple varieties are more resilient to climate change, suggesting they should be promoted (Veteto and Carlson 2014). Breaking cross-system lock-ins also requires changes to global food system rules, such as reforming financial systems to prevent funding unsustainable food production and promote commons-based, regional food systems (Béné 2022). These efforts can be supported by a clear narrative that challenges unsustainable discourses and highlights why transformation is necessary and achievable (Vaara and Whittle 2021).

Breaking cross-system lock-ins may require leveraging opportunities created by environmental, social, political, or economic crises that disrupt unsustainable systems. For example, air and water pollution crises have sparked major reforms in environmental regulation in countries, such as the United States in the 1970s and China in the 2010s. These kinds of environmental crises can catalyse change and break lock-ins, for instance, leading to the expanded use of solar energy to reduce import dependency, improve the environment, create jobs, and foster innovation (Kussul and Drozd 2023). Similarly, large-scale events like the Olympics, FIFA World Cup, or G7 summits can create opportunities for policy shifts, prompting politicians to propose sustainability initiatives.

In addition to seizing some of these opportunities, deeper shifts in values, such as ethics of care and reciprocity for life, are crucial. Such shifts should focus on deconstructing imaginaries, power structures, and human-non-human relations (Feola, Vincent, and Moore 2021). Goldstein *et al.* (2023) argue that comprehensive analyses of lock-in phenomena can help identify which challenges to overcome and which explanations to prioritize.

There is no one-size-fits-all approach to turning cross-system lock-ins into opportunities. Overcoming multiple interrelated barriers to break cross-system lock-ins benefits from a mix of strategies, including big plans, small wins, and systemic rule changes (Termeer *et al.* 2024). These approaches can gain traction when crises or major events disrupt incumbent interests and existing institutions. Sustainable transformation is also more likely when supported by ongoing efforts to address the underlying causes of cross-system barriers and lock-ins.

21.4 Leveraging motivation

This section focuses on the agents of change who can overcome the interrelated barriers and cross-system lock-ins discussed in the previous section, through common portfolios and joined-up agendas. It also sets out several motivators that can balance power-interest dynamics and strengthen collective action towards cross-cutting system transformation.

21.4.1 Agents of change

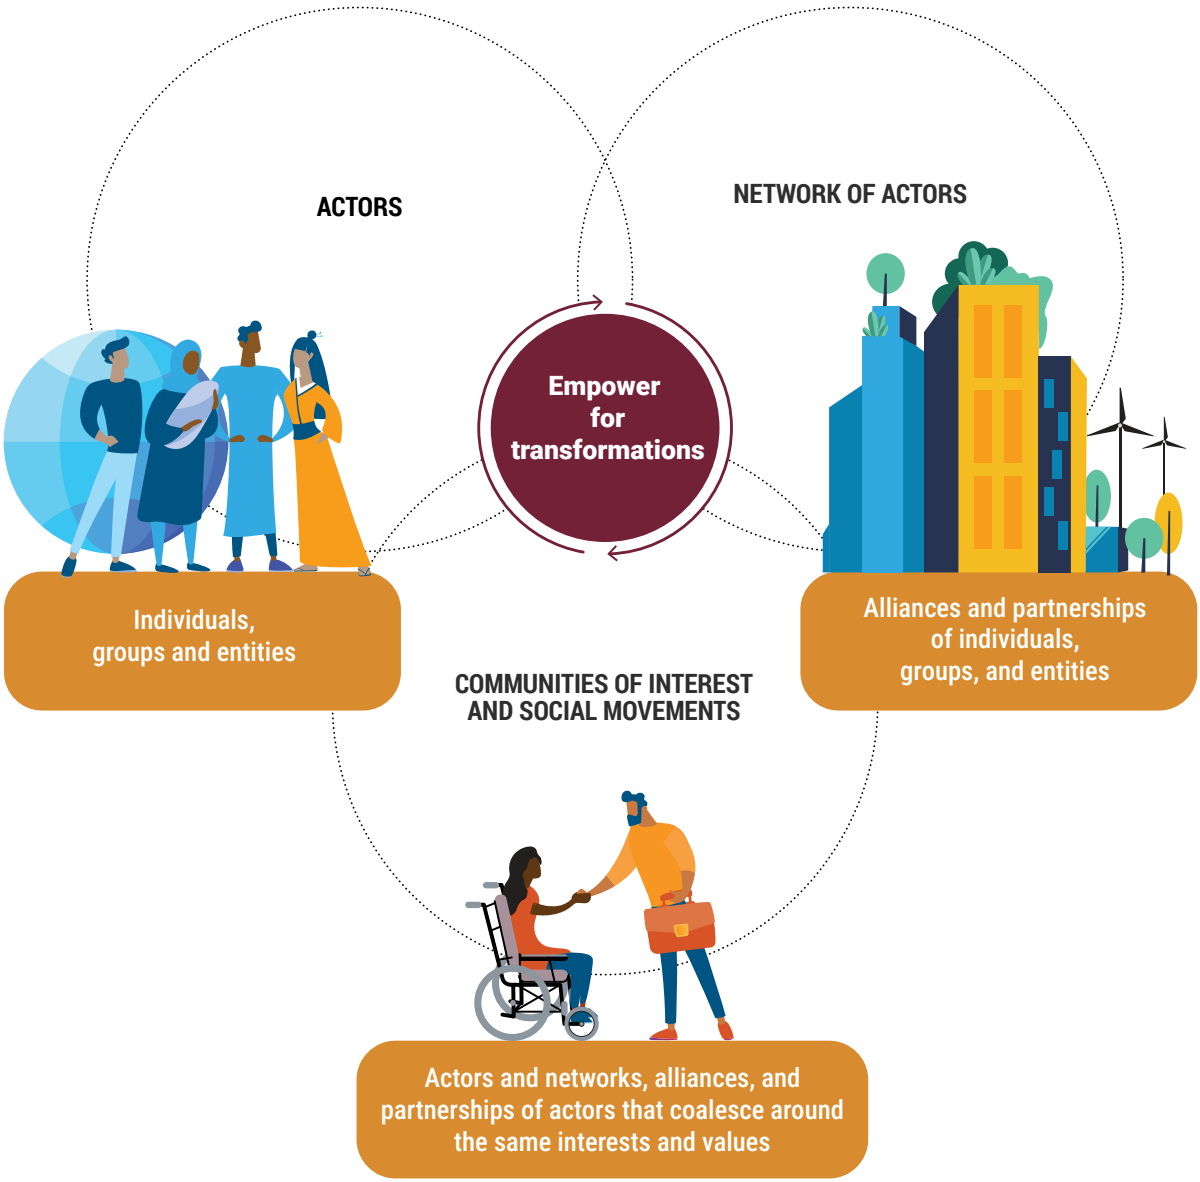
Agents of change are entities that perceive a problem as salient or dominant and act in a goal-directed manner to resolve it (Liefferink and Wurzel 2017; Birchall and Bonnett 2021). They enact agency, which can be human – in the form of will, rational deliberation or control over actions and subsequent consequences (Liefferink and Wurzel 2017; Birchall and Bonnett 2021) – and non-human – such as natural forces but also things, plants and animals in Indigenous cultures that drive earthly responses (Duerbeck, Schaumann and Sullivan 2015). Such agents are also material or immaterial, formal or informal, and can form networks and coalesce around a common interest or problem.

Systems exist and co-exist with and within multiple types of agents. Interactions within and across systems among agents can lead to system-wide behavioural shifts, influencing and affecting each other in potentially transformative ways (Arnold and Wade 2015). This is discussed at length in Chapters 14–18. The agents of change are grouped into three categories for ease of understanding (**Figure 21.2**):

- Actors
- Networks of actors
- Communities of interest and social movements

21.4.1.1 Actors

Actors were introduced in 12.4.5 and include individuals, groups, or entities affecting or affected by crises. They hold a stake in outcomes and can intentionally or unintentionally influence, shape, or initiate processes positively or negatively (Chinyioand Olomolaiye 2009). This chapter distinguishes actors from stakeholders to move discussions beyond rights holder debates and human-centred classifications.



The seven main categories of actors are as follows: governments; intergovernmental organizations; the public including Indigenous Peoples; civil society; the private sector; academia and professional associations; and nature. **Table 21.3** briefly defines and summarizes these actors and their roles. This chapter argues that nature is an actor and must be viewed as an equal partner at the decision-making table. This view builds on IPBES (2019), the EEA's narratives for change series (Benini and Viaud 2020) and UNEP's report on Nature in the Boardroom (2024), but also relational thinking from Eastern philosophy and Indigenous cultures, emphasizing unity between people and nature (Strand *et al.* 2023; UNEP 2024).

21.4.1.1.1 Governments

Governments at the national, regional and local levels can play a pivotal role in transforming systems. They are integral to transformation because they formulate the policies, regulations and strategies that influence a system's direction and priorities. For example, they are typically responsible for formulating and implementing agriculture, trade, nutrition, and overall sustainable agriculture policies that can influence key outcomes and the overall structure of a food system.

National governments are viewed as actors with high powers and interests. For instance, national

Figure 21.2: Three categories of agents of change actors

governments can determine whether to employ market-based or command-control instruments to curb pollution. They can also decide whether to support international programmes such as Energy for All and play a key role in driving both environmentally sustainable and socially just transformations. Local governments vary in power depending on a country's political system and governance structure, such as centralized or decentralized systems. Scandinavian countries have strong national and local governments, while Switzerland, China, and the United States of America have stronger national governments. In Sweden, local governments have significant autonomy in areas like education, healthcare and public transportation – this is strengthened through constitutional guarantees and financial independence (Lidström and Madell 2021).

21.4.1.1.2 Intergovernmental organizations

Intergovernmental organizations play a coordinating and norm-setting role in system transformations at the global level, often with low powers and interests at the national level. They provide guidelines, frameworks, programmes and platforms for global collaboration. Examples include the EU Green Deal driving global sustainability efforts through policy alignment (Oberthür and Dupont 2021; Cordella and Sala 2022) and the UN's

Table 21.3: Categories of actors, their definitions and roles

Actors	Definition	Role
Governments States, federations, ministries, regions, municipalities.	Governance, regulatory, and administrative structures shape national or jurisdiction-wide decisions.	Governs, protects rights, enforces laws, and mediates interests across levels within nation states/ national jurisdictions.
Intergovernmental organizations United Nations, World Bank, European Union, World Health Organization.	Formed by multiple countries through treaties or agreements to collaborate on common issues, such as security, trade, or environmental protection.	Makes international policy, lobbies international laws and regulations, coordinates nations, provides aid, and safeguards planetary health.
The public Laypersons, citizens, voters, local communities, Indigenous Peoples	The collective population of a society or community, including individuals and groups.	Acts on rights, consumes, owns, experiences transformations, and produces citizen science.
Civil society NGOs, Oxfam, Greenpeace, WWF, foodbanks.	The sum of non-governmental organizations and voluntary groups that operate independently from the government at various levels.	Advocates for marginalized groups, lobbies for change, takes a participatory approach, and promotes public interest, social welfare, and community engagement.
Private sector Corporations, multinationals, SMEs, start-ups, banks.	Owned and operated by private individuals or businesses who aim to generate profit.	Delivers goods/services, makes profits, provides investment, and has fiduciary duties to shareholders.
Academia and professional associations Universities, research institutes, engineering/ medical associations	Undertakes education, research, and the advancement of knowledge in specific fields.	Provides education, research, develops standards, and co-produces evidence-based solutions.
Nature Ecosystems, plants, animals, air, water, soil, natural resources.	The physical world exists independently of human 'creation', including living organisms, landscapes, and natural processes, and subsequent resources and services provided.	Contributes intrinsic, instrumental, and relational values, provides ecosystem services, absorbs environmental impacts, and causes unpredictable events like tides, eruptions, and extinctions. It is foundational to the stability, productivity, and long-term sustainability of all human and ecological systems.

Source: Adapted from Ginige, Amaratunga, and Haigh 2018

Global Framework for Climate Services that facilitates the delivery of climate services for Member States (United Nations 2016). Intergovernmental organizations can also set laws for environmental protection, such as the EU's Nature Restoration Law, or put pressure on nature rights under the ICC Legal Framework Concerning Victims (Lostal 2024).

21.4.1.1.3 The public

The public includes individuals as well as communities or groups of people who may not have a formal affiliation (Tsingou 2015). The public can influence system transformation by exercising preferences and choices: changing consumer demand for healthier, sustainably sourced and ethically produced food can drive transformation in the food system (17.2). The public can also influence outcomes by mobilizing to counter environmentally harmful practices. Examples include protests against fracking in the United States of America, leading to policy changes and moratoriums in states such as New York (Negro 2021; Graham and Rupp 2022; Young 2023), or community-led pressures around environmental and health concerns in United

Republic of Tanzania that led the government to re-evaluate its uranium mining policies in the Selous Game Reserve (Kileo *et al.* 2019; Muhanga 2019). The public also drives transformations through citizen science, shaping pathways based on local knowledge and goals for meaningful, measurable change.

21.4.1.1.4 Civil society

Civil society organizations play an active role in driving systemic transformations (Mohr, Raman and Gibbs 2013). While some non-governmental organizations face criticism for imposing their views (Büscher and Fletcher 2019), they can drive transformation and advocate for reducing ecological footprints and improving health and well-being. To illustrate, the Centre for Science and Environment in India campaigned for stricter air pollution standards, leading to the Bharat Stage VI vehicle emissions standards in 2020 (Roychowdhury *et al.* 2019; Khodke, Watabe and Mehdi 2021). The Kenya Climate Justice Women Champions, to highlight another example, have advocated for gender-sensitive climate adaptation and mitigation strategies (Esipisu 2013; Gicheru, Mwenda and Omwami 2024).

21.4.1.1.5 Private sector

Some private sector actors hold significant power and interest in sustainability, particularly in driving transformations in materials/waste (15.2) and energy systems (16.2). With clear policy direction, such actors can play a pivotal role in enabling change. For example, in Germany, Siemens and Volkswagen have supported renewable energy and electric vehicles in line with Energiewende (Pons-Seres de Brauwer 2022). At the same time, private sector choices can also slow transitions, as in Australia, where BHP Group, formerly Broken Hill Proprietary Company, was criticized for fossil-fuel investments that conflicted with renewable energy goals (McDonald *et al.* 2023). Large agribusinesses and food retailers influence food systems by shaping production, supply chains, and marketing, and making food decisions that can drive changes in the types of foods available and their effect on health and the environment. In Brazil, for example, JBS multinational has been linked to deforestation through large-scale cattle ranching (Rajão and Soares-Filho 2015), while in Indonesia, Wilmar International's palm oil production has had impacts on biodiversity (Brandi *et al.* 2015). Small-scale farmers' and food producers' can strengthen resilience in the food system through agroecological practices and socially inclusive approaches, though their influence may be more locally situated. Across regions, private sector actors are sometimes challenged for market-driven interests and greenwashing, however, their remain key to sustainable transformations. Environmental regulations and public education are important strategies to counteract this tendency (Flores and Rodríguez 2013).

21.4.1.1.6 Academia and professional organizations

Academic institutions and professional organizations drive system transformation through research, innovation, knowledge sharing, and educating future generations for societal change. Academic research informs policy- and decision-making processes and provides support for evidence-based projects and initiatives. Research-based organizations continuously experiment and seek alternatives by, for example, using art to unpack ontologies and values. Moreover, the academics that work in these organizations are often using feminist-, intersectional-, Indigenous- and decolonial-based perspectives to challenge the existing understanding of the environment (Arora and Stirling 2023).

21.4.1.1.7 Nature

Nature encompasses all living and non-living things that occur naturally without human intervention, including flora, fauna, resources, soil, water, and air. Some regard humans as part of nature, with Indigenous Peoples, Shintoists, and Buddhists perceiving nature as a complex web of life, where humans are integral to nature in a 'vital complementarity' that entails associated obligations and responsibilities for care (UNEP and ISC 2024, p. 18). Recognizing the perspectives and associated practices in which humans coexist with nature (IPBES 2022) is central to sustainability transformations. This requires shifting from anthropocentric to biocentric, ecocentric, and pluriversal approaches, and viewing nature as having intrinsic value and holding the knowledge and agency that drive transformation. Nature's agency is shown through unpredictable events that can either benefit or devastate ecosystems, such as the Permian-Triassic Extinction – which wiped out 90 per cent of marine species and 70 per cent of terrestrial species

– and volcanic eruptions and tsunamis that have been the cause of death over many millennia (NCEI/WDS 2024).

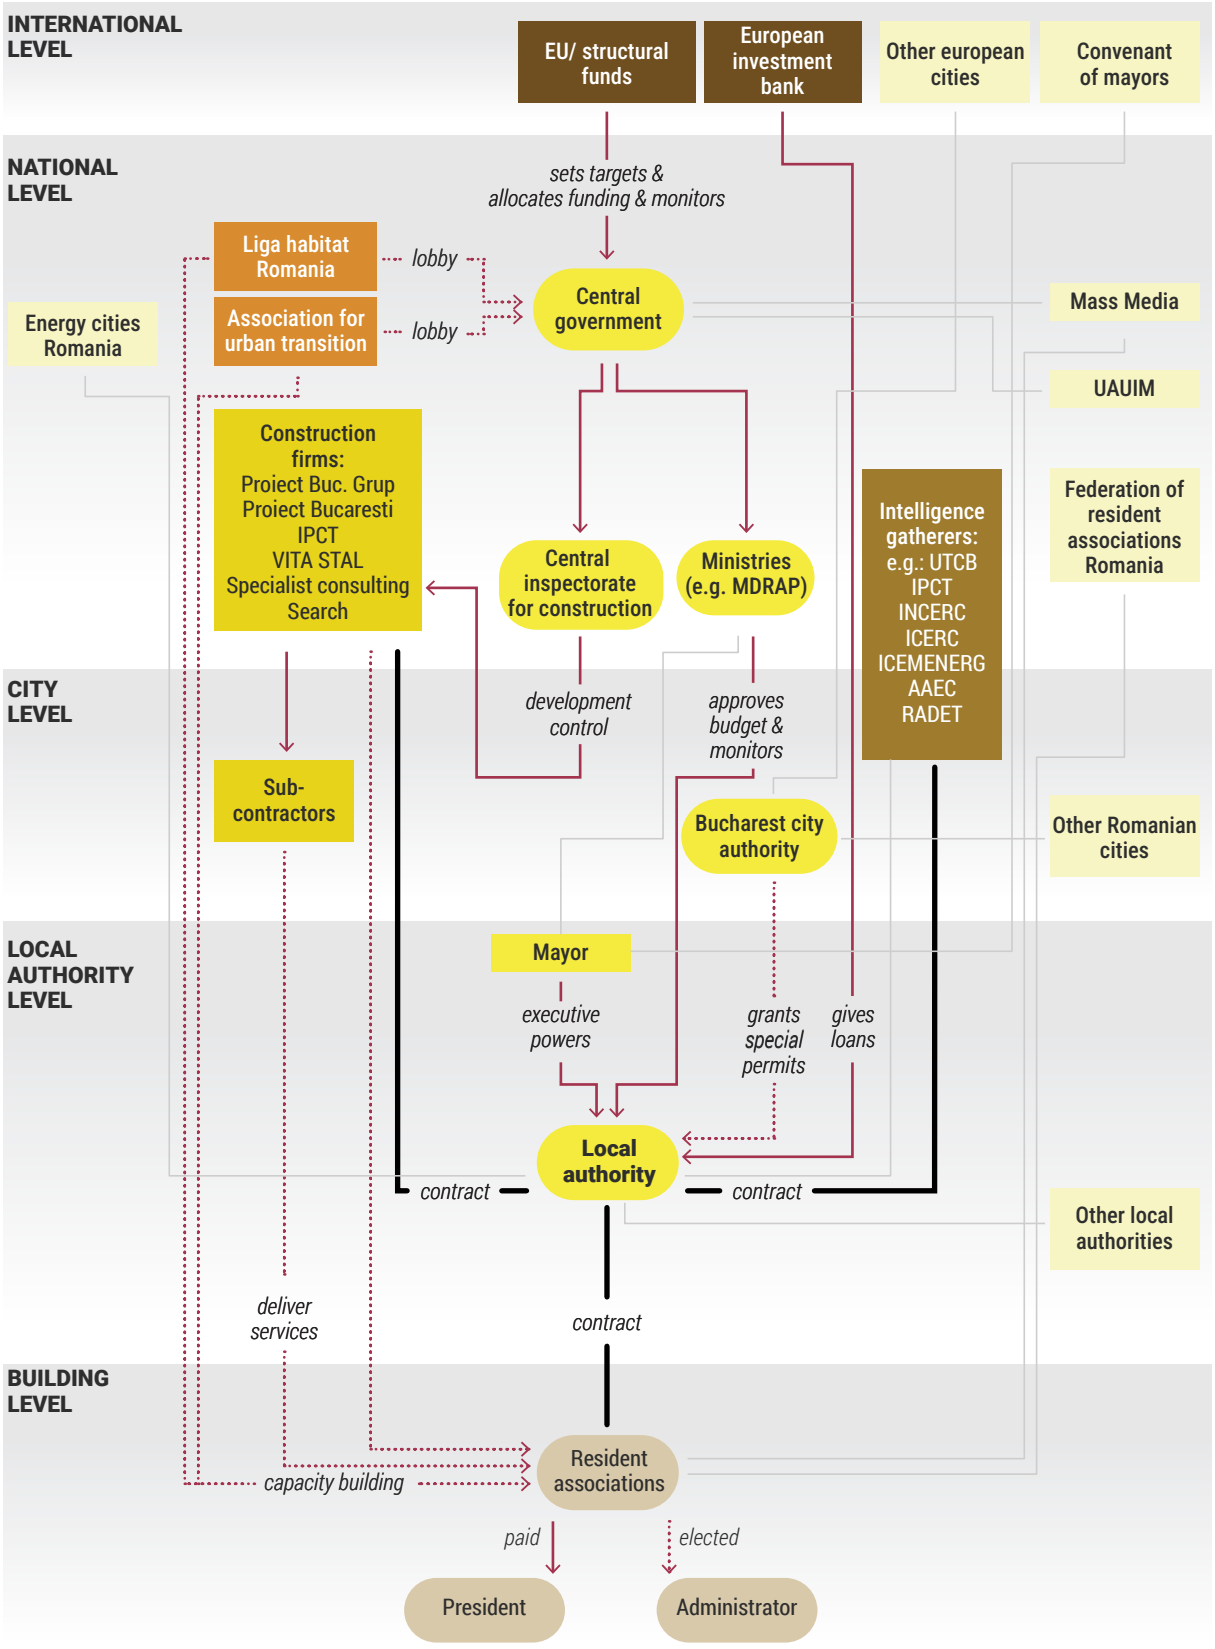
21.4.1.2 Network of actors

Actors seldom act in isolation. They form alliances or partnerships called networks of actors that not only help to break different kinds of lock-ins, but also determine system, societal and geographical conditions. **Figure 21.3** shows the complexity of networks of actors involved in the decarbonization of Romanian housing. Six networks of actors, forming constellations of interests and powers and linked by feedback loops, span multiple sectors and scales in the energy and housing systems (Turcu 2017).

Other networks of actors include UN regions, development categories such as high-income countries (HICs), least developed countries (LDCs), and small island developing states (SIDS), and cities. Cities are at the forefront of fighting multiple crises and are seen as instrumental in implementing solutions that can drive systemic transformations, overcoming barriers and lock-ins. They often lead from the front by rejecting coal and promoting clean energy, as well as advancing circularity by promoting zero-waste policies (Turcu 2023; Pincetl 2017). Cities play a growing role in climate negotiations over issues such as nationally determined contributions, the global goal for adaptation, and the loss and damage fund, with the Intergovernmental Panel on Climate Change planning a dedicated report on cities for the seventh assessment cycle.

21.4.1.3 Communities of interest and social movements

Communities of interest are actors or networks of actors united by shared values or goals, often collaborating to address issues such as rights, environmental protection and social justice (Turcu 2010). Communities of interest, also known as alliances, partnerships or assemblages, tend to transcend geographical boundaries and can unite activists, scientists, policymakers, governmental bodies, private businesses, their networks and associated resources. Examples include slow-food communities and food councils that advocate for sustainable agriculture and food localization, Zapatista groups for Indigenous justice in southern Mexico, and the International Land Coalition supporting Indigenous land rights and management. Communities of religious or spiritual interest can also drive system transformations by leveraging their moral authority, organizational capacity and influence to change social values, norms, behaviours and practices. The Catholic Church's 'Laudate Deum' and Interfaith Power & Light advocate for climate action and reducing carbon footprints (Northcott 2015).



Social movements are collective actions by actors or networks of actors aiming to shift values and practices, for example, climate, youth, or educational movements. They campaign for environmental justice, engage grassroots communities, build shared identities, expand political opportunities, and mobilize resources to drive sustainability (McAdam 2017). For instance, Fridays for Future, led by Greta Thunberg, mobilizes youth worldwide for climate action, influencing policy reforms in Sweden, France, the UK and Germany (Thunberg 2021). Other examples include India's Chipko and Niyamgiri movements, the Chico Mendes movement in Brazil, Buen Vivir in Latin America, West Harlem Environmental Action in the United States of America, and Africa's Alliance for Food Sovereignty (Arora and Stirling 2023).

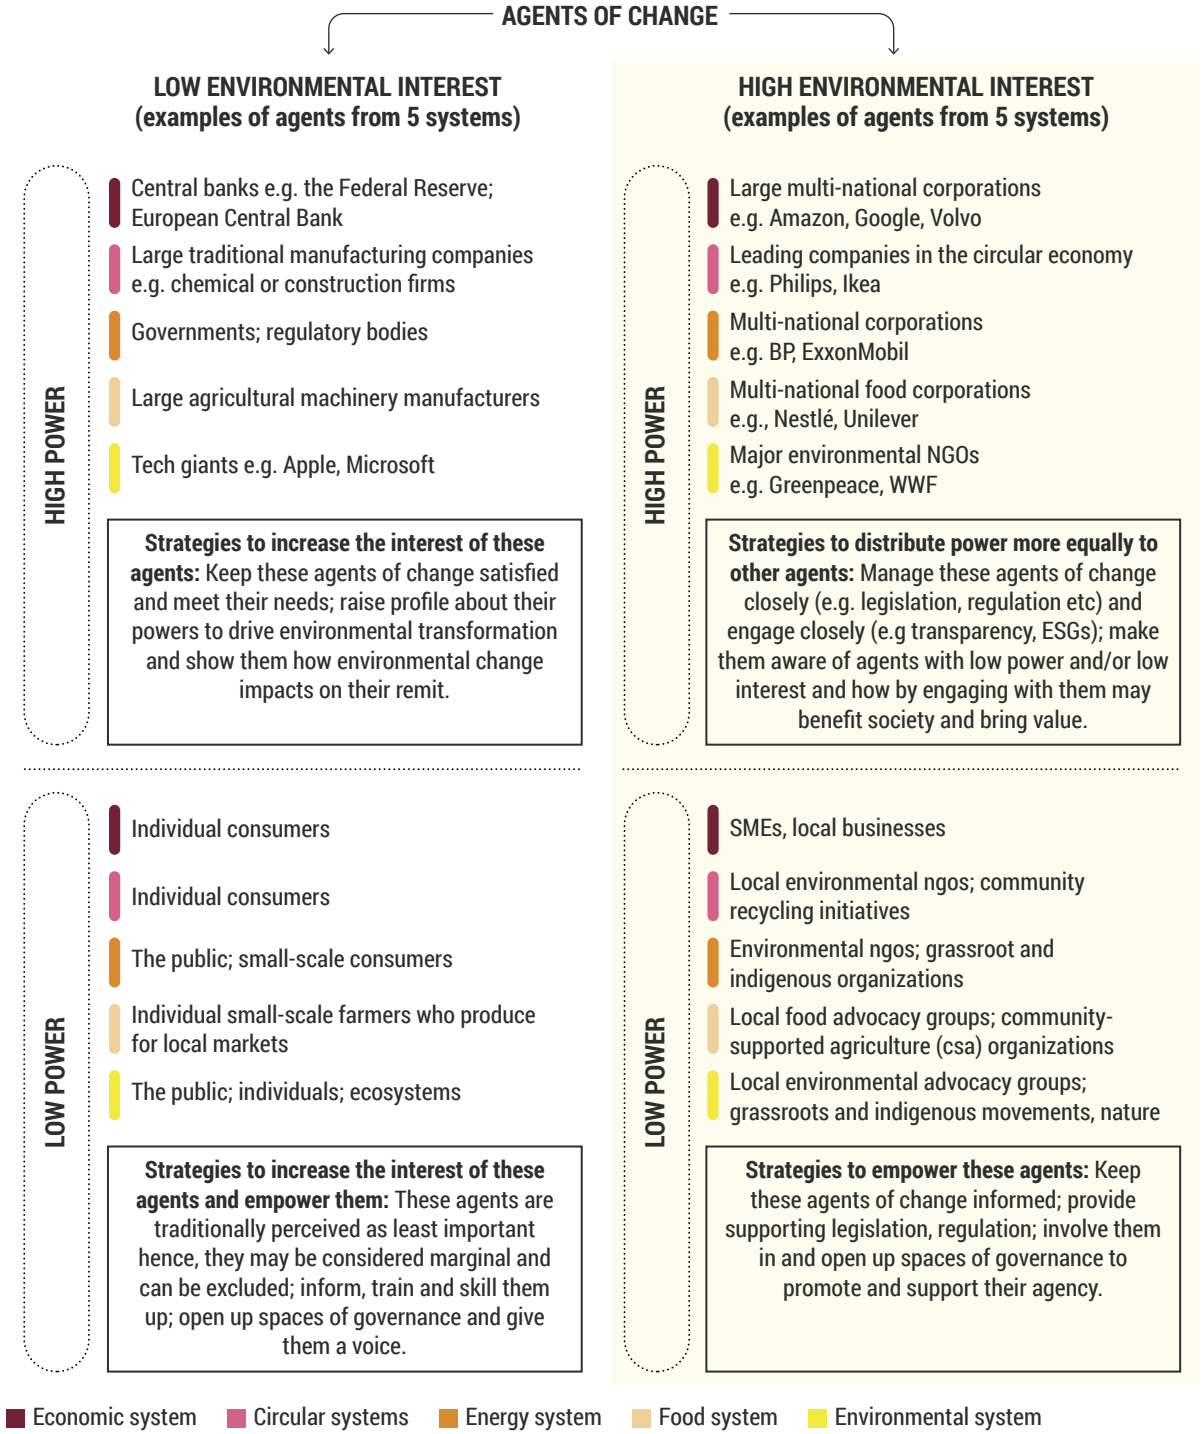
21.4.1.4 Power-interest dynamics

Agents of change are framed by power-interest dynamics. Power is the ability to act and create change, while interests involve holding a stake in outcomes through authority, responsibility, ownership and influence (Chinyio and Olomolaiye 2009). Power-interest dynamics shape change by influencing voices and solutions. For example, in the energy system, corporations and governments drive transformation through financial and regulatory power (Sovacool 2016), while in the materials/waste system, power-interest dynamics among agents of change shape circular practice development and implementation (Turcu and Gillie 2020).

The two-by-two Mendelow's Matrix (1981) provides a useful tool to map, categorize and manage agents based on their power and interests. **Figure 21.4** highlights how some agents are marginalized in decisions that shape their future due to their perceived low power or interest in environmental transformation. Traditionally, multinational corporations hold high power and interests, while the public and individuals have low power and interest. Non-governmental organizations and grassroots organizations have high interest but low power. Driving transformations requires empowering all agents, addressing power imbalances, and increasing engagement. **Figure 21.4** suggests strategies to achieve this.

Figure 21.3: Six networks of actors in housing decarbonization in Romania: handlers, controllers, intelligence gatherers, deliverers, non-governmental, clients

Source: Adapted from Turcu (2017)



21.4.1.5 Common portfolios and joined-up agendas

Collaboration among agents of change helps overcome barriers and lock-ins, turning them into opportunities. This often entails developing common portfolios to drive transformation. A common portfolio approach mitigates risks, cross-system lock-ins, and uncertainties by fostering collective action and aligned agendas (Pereverza, Dierks, and Järvelä 2022).

Figure 21.5 shows how agents collaborated during the COVID-19 pandemic in London to create a common portfolio of actions in response to disruptions to access to food, highlighting the need for a more resilient urban food system (Turcu and Rotolo 2022).

The ban on single-use plastics across the world shows multi-agent partnerships driving significant environmental change through common portfolios of shared initiatives. Over 91 countries, including over

Figure 21.4: The power-interest matrix with examples from the five GEO-7 systems

30 in Africa, have banned single-use plastic bags, with Kenya enforcing the world's strictest ban in 2017 (UNEP 2018) and the EU's 2021 ban on single-use plastics like straws, cutlery, and cotton buds marked a major shift in its environmental and waste policies (European Commission 2021).

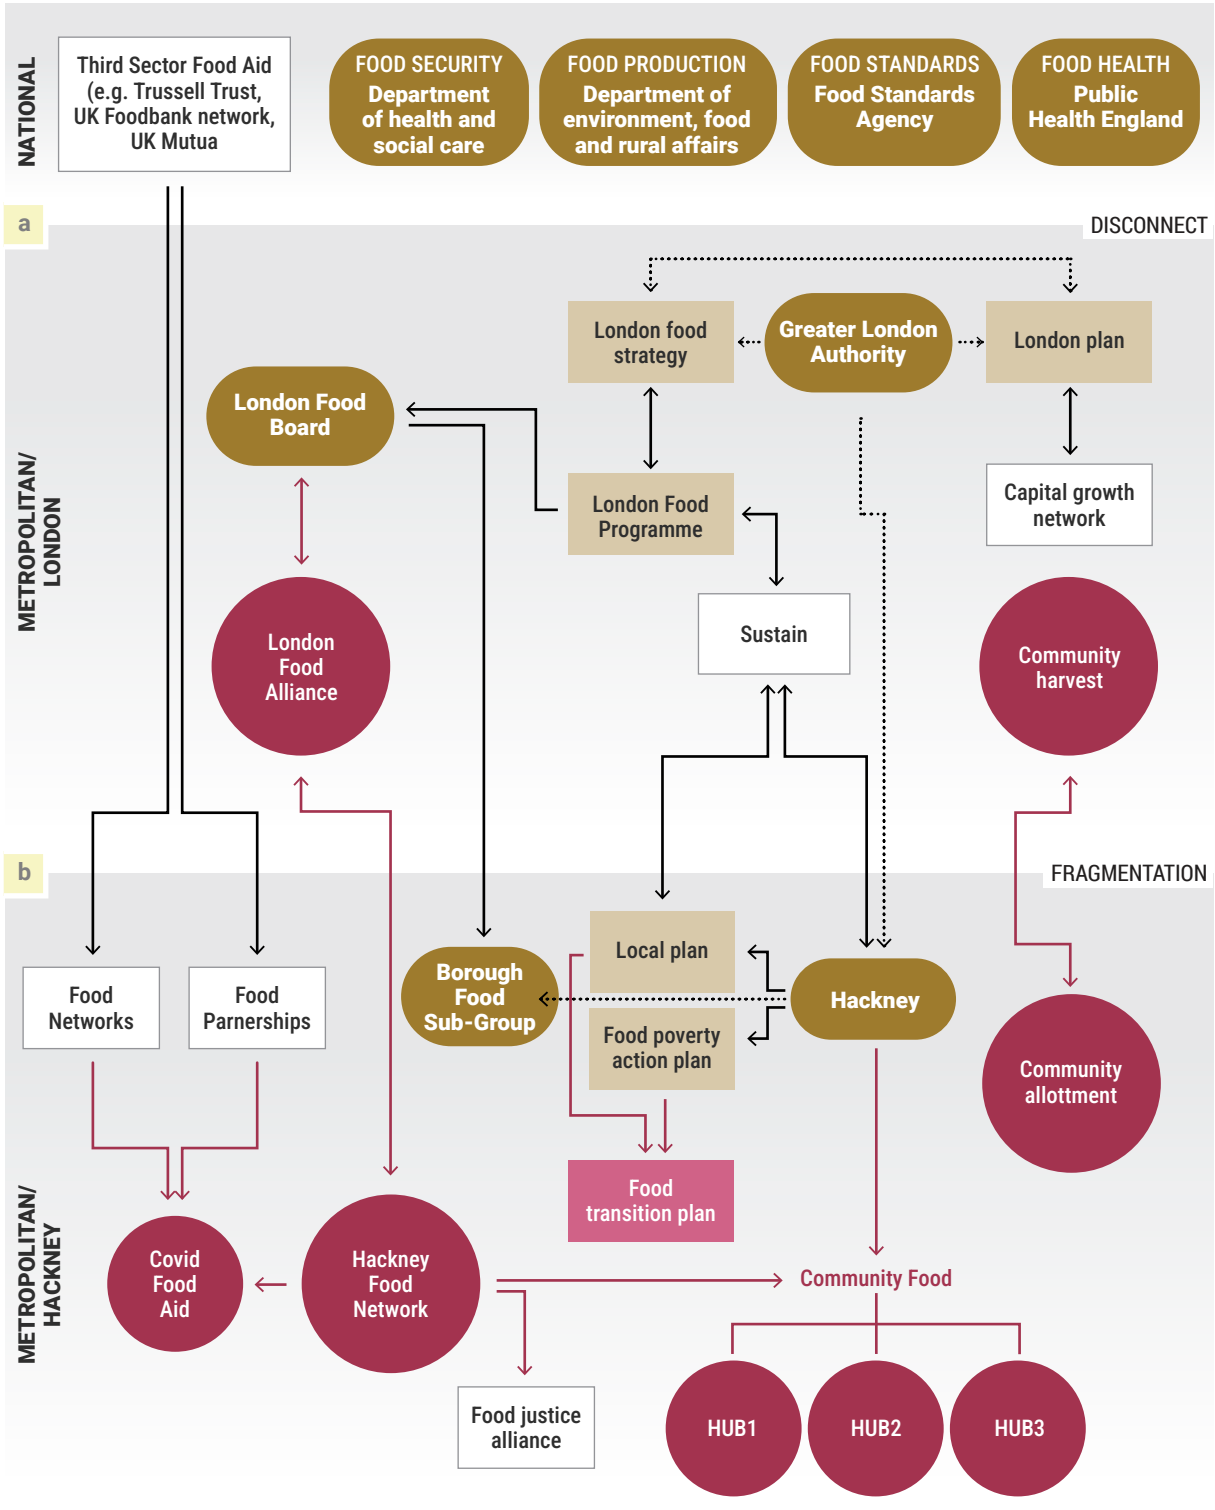
21.4.2 Key motivators

Accelerating a sustainable transformation often requires motivating agents of change into action. Motivations reach beyond domains of intentional action – such as levers, defined in 12.5 – to the ontological claims underpinning such action. Motivators are sets of constructs that induce agents of change to take action. Motivators stem from external and internal factors – including economic, technological, regulatory, and psychological factors – and can be explained in various ways (**Figure 21.6**). These motivators influence agents of change and systems, shaping perceptions of right and wrong, feasibility, legality, and ethical responsibility beyond individual actions (Turcu 2018).

Four categories of motivators are identified in this chapter:

- Health and well-being
- Economic and financial stimuli
- Regulatory frameworks
- Culture, imaginaries, social norms, common values and beliefs

Table 21.4 shows how the four motivator categories frame agency and drive action from agents of change based on different theoretical perspectives from **Figure 21.6**.



21.4.2.1 Health and well-being

A fundamental motivator for agents of change is ensuring their survival, health and well-being, which in ecological terms means preserving the vitality of ecosystems for human life. This has gained attention in environmental policy due to evidence linking planetary and human health, with studies showing that climate change, biodiversity loss, pollution and

Table 21.4: Explaining how agents of change are motivated to action through the various theoretical 'lenses described in Figure 21.6

Motivators	Understanding motivators through different theoretical lenses
Health and well-being	• Agents of change are motivated by scientific evidence about environmental crises and their measurable threats and implications on health and well-being (positivism) • Agents of change are motivated by their interpretation of health risks, drawing on dominant cultural norms, social understandings, their experiences and social interactions. (interpretivism and phenomenology)
Economic and financial stimuli	• Agents of change are motivated by economic incentives, such as subsidies and profit margins, that make transformation financially viable. (pragmatism) • Agents of change are motivated by economic policies and market forces; however, they are co-creators of these forces, capable of resisting, reinventing or innovating on the basis of their interests. (critical realism)
Regulatory frameworks	• Agents of change are motivated by laws and regulations, and when their actions are incentivized or penalized. (structuralism) • Agents of change are motivated by legislative or regulatory incentives and sanctions, but they interpret, resist or creatively adapt to restrictions. (critical realism)
Culture, imaginaries, social norms, common values and beliefs	• Agents of change are motivated by societal imaginaries and common values and enabled or deterred from action by cultural and social norms. Transformation is driven by changing imaginaries, cultures, social norms, values and beliefs. (Interpretivism and constructivism) • Agents of change are motivated by changes in cultural narratives and power dynamics, determined by the inclusion of marginalized groups and Indigenous Peoples. (Post-structuralism)

Box 21.4: Definitions of health

Health and well-being – The World Health Organization defines health as "complete physical, mental and social well-being and not merely the absence of disease or infirmity", recognizing the interconnections between social, psychological, and medical factors.

Planetary health – Emphasizes the interconnectedness of human and planetary health, using a holistic approach to promote health, equity, and sustainability amid global environmental challenges.

One Health – Acknowledges the interconnectedness of human, animal, and environmental health, offering a framework for evidence-based policies and solutions to protect all three.

land degradation harm both human and planetary health (Crane *et al.* 2021). The recognition that human and planetary health are interconnected has led to efforts to better assess the health effects of environmental policies and vice versa, with current research documenting, for example, the health co-benefits of climate action (Turcu 2025). This need for integration is highlighted in the 2023 Lancet Countdown Report, which stresses the "imperative for a health-centred response to irreversible environmental harms" (Romanello *et al.* 2023).

Scientific evidence highlights the strong link between climate change and health, emphasizing direct and indirect effects, health inequalities, economic costs, and the health co-benefits of climate action. These arguments can motivate or induce change by demonstrating how climate policies save lives and reduce healthcare costs (Romanello *et al.* 2023; Turcu 2025). Costa Rica, for example, has been successful in integrating its economic model with health, education and environmental development (**Box 21.5**).

Agents of change are increasingly using health and well-being as a justification for accelerating transformation, and there is a growing interest in how nature and health reinforce each other (**Box 21.6**). Nature-based solutions, nature restoration, and rewilding policies can boost biodiversity, promote physical activity, improve health, reduce environmental stress, and enhance cooperation among agents of change. Indigenous Peoples and relational philosophies and ways of living teach us that humans are part of a living whole, emphasizing harmony on nature (**Box 21.7**).

21.4.2.2 Economic and financial stimuli

Driving transformations often involves shifting away from dominant economic paradigms and market values. Arguments about the limits to growth are not new, and evidence shows that green growth is too slow, small-scale, and short-lived, suggesting a need to shift toward 'beyond-GDP' models. However, some agents of change may initially require economic

Box 21.5: Costa Rica's government makes bold investments in public health, education, and environmental protection

Costa Rica outperforms its Central American neighbours in quality of life and is among the world's happiest and most sustainable countries according to The Happy Planet Index (The Hot or Cool Institute 2021). Since abolishing its army in 1949, Costa Rica has prioritized social investment through tax reforms, funding public health, education, and environmental protection (Oviedo et al. 2015). This approach has led to universal healthcare, pensions, and primary education, resulting in high literacy, low infant mortality, long life expectancy, and relatively low poverty by Latin American standards. Costa Rica has set up the world-renowned Green Trademark, a payments for environmental services programme, and a thriving ecotourism industry by prioritizing biodiversity. Further, over 99 per cent of Costa Rica's electricity comes from renewables, with fossil fuel taxes helping to fund forest protection (Bertelsmann Stiftung 2013). Achieved with a fraction of Western resources, these efforts have led to well-being indicators comparable to or above the OECD average (OECD 2017).

Figure 21.6: How varying theoretical lenses describe motivations or motivators

Positivism

External factors - economic, technological, and regulatory - drive human agency and shape collective action (Riley, Emigh and Ahmed 2021; Verbeek 2023).

Critical Realism

Behaviour is shaped by both societal structures and agent agency and, action influenced by constraints and choice (Dreyer et al. 2022).

Post-positivism & Structuralism

Psychological structures - cognitive bias, values, norms, and perceptions - shape human behaviour (Sussman & Giffort 2019; Falcone et al. 2024; etc.), and influenced by social and cultural factors - such as norms, language, stereotypes, and power hierarchies - followed by individuals subconsciously.

Human action is guided by societal rules and structures, and agents of change act in alignment with their cultural context and values.

Poststructuralism & Relationism

Challenge universal structures in language and culture, emphasizing the politics of knowledge, role of institutions, and the agency of non-humans (Puig de la Bellacasa 2017; Haraway 2016).

Pragmatism

Human agency is driven by practical outcomes - such as impact, competence - and their ability to shape desired futures (Emirbayer & Mische 1998; Goller 2017).

Interpretivism, Constructivism & Phenomenology

Build on the post-positivist and structuralist construction of psychological structures and view human agency as dynamic and subjective, emphasizing that actions stem from personal interpretations of surrounding contexts (Blumer 1969; Franzese & Seigler 2020).

and financial incentives to align their interests and recognize the benefits of their actions. An increasing number of businesses recognize the need for profound changes in resource-intensive systems to sustain their ventures, as reflected in several prominent economic forums. For example, the World Economic Forum (2022) recognizes the need for systemic transformation for and by business, while the World Business Council for Sustainable Development (2020) advocates for transformative changes in sustainable systems.

In addition to more conventional economic and financial stimuli, nature-positive economic approaches are also gaining traction globally, recognizing a dependence on nature. For instance,

Box 21.6: The multiple benefits of nature

Growing evidence highlights that forging connections with nature has multiple benefits – sometimes referred to as the health benefits of nature connectedness. Natural elements such as parks, urban forests, and wetlands enhance biodiversity and water quality while promoting physical activity, relaxation, and social connections. These elements improve health and well-being while helping communities adapt to climate change by cooling temperatures, improving air quality, managing floods, supporting groundwater, and sequestering carbon (Turcu 2025). Many frameworks and resources help agents of change leverage the benefits of nature to enhance sustainability, health, and quality of life. Examples include ICLEI's BiodiverCities, C40's Urban Nature Accelerator and the UK's National Biodiversity Network.

the UK, in partnership with the UNDP's Biodiversity Finance Initiative and Financial Sector Deepening Africa (FSD-Africa), launched the Nature-Positive Economy programme to help less-developed countries transition to nature-positive economies. The programme supports the management of nature-related financial risks, the integration of nature into decision-making, the development of Action Plans for Nature, and the enhancement of evidence sharing (Dasgupta 2021).

21.4.2.3 Regulatory frameworks

Legislation and regulations aim to protect the common good and public interest, primarily from a human-centric perspective. Regulatory frameworks ensure resource distribution, sanction non-compliance, and limit harm to health and well-being. They define agents of change roles and responsibilities for the environment and support transparency and accountability.

Scientific evidence shows that environmental legislation and regulations often far outweigh their costs and can drive innovation and transformation across systems, with economy-wide benefits. This contrasts with the common belief that regulatory frameworks hinder market function, productivity, employment, and international competitiveness (Dechezleprêtre and Sato 2017). In reality, developed countries tend to have stronger environmental regulatory frameworks (Li and Ramanathan 2018; Stef and Ashta 2023), while evidence shows that in countries with a weak rule of law, corruption, injustice, inequality are associated with higher environmental degradation: and socioeconomic disparities.

Legislation and regulation can motivate agents to act and are viewed as key drivers in UNEP's Environmental Rule of Law. This report stresses that, amid multiple environmental crises, the environmental rule of law is more crucial than ever (UNEP 2023). It further finds that the COVID-19 pandemic positively influenced environmental legislation, with greater recognition of environmental rights, improved enforcement, and increased accountability. The report also highlights women's role in environmental reform, and the opportunities technology presents. However, it notes that the focus on climate change legislation often overshadows other environmental challenges.

Some countries have grounded their development and democracy in environmental legislation and regulation. Sweden's Environmental Code, established in 1998, consolidates 15 laws to ensure a healthy environment for current and future generations. It includes the polluter pays and precautionary principles, as well as advocating for product choice, resource management, recycling, and rules for appropriate site selection for activities. In 2017, this was complemented by a climate policy framework featuring a climate act, climate targets, and a climate policy council to help achieve net-zero GHG emissions by 2045 (Matti, Petersson, and Söderberg 2021).

Recently, there has been growing recognition that human-centric environmental laws can be complemented by those acknowledging nature as a rights holder. Earth jurisprudence is a legal philosophy that views humans as part of a broader community, where the welfare of each member depends on the well-being of the Earth as a whole (Cullinan 2011). It is closely linked to the legal concept of granting

Box 21.7 Nature-positive economy and the Aymara people

A nature-positive economy prioritizes ecosystem well-being and biodiversity, aiming for sustainable development that benefits both the environment and society. It includes practices such as conservation, restoration, and regenerative agriculture, promoting harmony between human activities and nature for long-term resilience. The Aymara people of the Andes have developed a worldview called "living well", where their needs – food, water, work, and care for the vulnerable – are met in harmony with the environment. This earth-centred philosophy has allowed them to thrive for millennia in harsh conditions without harming their natural surroundings.

natural entities legal personality and recognizing them as subjects of rights.

In 2018, Colombia's Supreme Court ruled in favour of a group of Indigenous Peoples, granting the Colombian Amazon rights to protect it from deforestation. This ruling is consistent with rights of nature, a legal and philosophical framework that has been recognized as helping to conserve biodiversity in many contexts by underlining that nature has rights comparable to humans (IPBES 2022). In fact, several countries, including Bolivia, Colombia, Ecuador, India and New Zealand, have adopted legal mechanisms granting rights of nature or legal personhood to non-human entities (Garver 2020; Darpö 2021).

21.4.2.4 Culture, imaginaries, social norms, common values and beliefs

Cultural and social norms, common values and beliefs can strongly motivate agents of change with action by shaping perceptions, fostering identity and solidarity, and providing a moral compass to guide actions.

Cultural narratives can mobilize social movements by aligning collective action and historical identity, and cultural norms can influence the implementation of policies. Sweden's love for nature is deeply rooted in Swedish culture and frames much of its environmental and sustainable spatial development policies (Turcu 2018).

Social imaginaries – defined as framings that are collectively held in a culture or social group – shape identities, notions of place and relations to others (Castoriadis 1994; Taylor 2004; Jasanoff and Kim 2015). They can be transformative by advancing pluralist and democratic ideas that challenge dominant and unsustainable hegemonies.

Social norms – the unwritten rules governing behaviour – can either support or hinder transformational change. Norms that value innovation, environmental stewardship, or justice can help agents of change by offering social approval, reducing risks, shifting behaviours, and creating tipping points for broader societal change (Bicchieri 2017).

Common values and beliefs from faith, religion, or Indigenous groups form the ethical foundation of society, guiding actions and shaping the aspirations of agents of change. When these agents align their actions with widely shared values, they are more likely to gain broad support and legitimacy. Values-driven transformation can inspire long-term commitments, as demonstrated by Indigenous leadership in sustainable land governance and biodiversity conservation.

About 80 per cent of the global population belongs to a religious or spiritual group (Hackett *et al.* 2012). Emerging evidence notes how religious teachings contribute to environmental protection debates and motivate transformational change by offering moral frameworks and fostering community mobilization.

Initiatives such as the Interfaith Rainforest Initiative, WWF's Sacred Earth: Faiths for Conservation, and UNEP's Faith for Earth: A Call for Action use faith-based principles to inspire environmental stewardship. WWF's Sacred Earth project works with religious communities to integrate conservation into their practices and promote environmental care. Many religions also embrace relational philosophies that connect humans to nature and emphasize ethics of care, which are vital for sustainability transformations.

It is important to note that rarely will all four categories of motivators be equally effective for all agents of change or across different systems, regions, or countries. However, a combination of motivators is more likely to inspire and drive action in sustaining and accelerating transformations. For example, **Table 21.5** illustrates how motivators can be used to align the interests of governments, the public, and the private sector in driving transformations.

Credit: NaturesCharm/Envato

Table 21.5: Using motivators to align the interests of governments, the public, and the private sector to drive transformations

Agents of change	Examples of interests	Examples of motivators for transformation
Governments	• Sustain economic growth, attract investment and improve the country's competitiveness • Comply with international standards • Protect public health • Ensure political legacy • Prevent future crises	• Use EF to support a nature-positive economy, such as Costa Rica's Payment for Environmental Services (PES) • Use RF to define roles and responsibilities for the environment, such as European Green Deal • Use HW to support 'Health-in-All Policies' (HiAP), UK's Ultra Low Emissions Zones (ULEZ), EU's Farm to Fork Strategy • Use SN to maintain political stability and support environmental decisions: New Zealand's legal personhood for nature; Bhutan's Gross National Happiness Policy • Use combinations of HW, EF, RF, and SN to manage risks and develop recovery plans
The public	• Personal and community health and well-being • Access to economic opportunities • Cost savings • Comply with social norms	• Use HW to demonstrate the benefits of unsustainable actions, e.g. smoking bans, sugar and fat taxes, congestion charges • Use EF to create new jobs in the 'green sector', and RF to ensure fairness and inclusion • Use SN and/or EF to reduce consumption or support alternative economic systems and barter communities • Use RF and/or SN to redefine acceptable behaviours, expectations, and sanctions
Private sector	• Reduce costs, increase profit margins; market expansion and competition (EF) • Brand reputation • Customer health and safety • Comply with regulations and legislation	• Use EF to support alternative market models, e.g. circular economy, eco-design, resource efficiency, renewable energy, carbon pricing • Use SN to reframe corporate social and environmental responsibilities, such as IKEA's re-use strategy, Patagonia's eco-friendly fashion • Use HW and/or RF to showcase or regulate health benefits and trade-offs of market choices • Use RF to enforce environmental actions and choices

21.5 Accelerating a sustainable transformation

The previous sections outlined three often related processes needed to drive a sustainable transformation: enabling participation in the co-production of futures and pathways, turning barriers of the existing development patterns into opportunities for change, and encouraging agents of change, including non-human agents, to work with motivators – health, economics, legislation, and norms – to expand these opportunities. This section reflects on not only how these processes can move forward to drive transformation, but also on how a multidimensional sustainable transformation can be accelerated.

21.5.1 What is acceleration and why do we need it?

This section, building on the definition and principles of transformation presented in 12.4 and

12.5, defines and discusses the need for acceleration. While there is no universal blueprint, at the most fundamental level, acceleration requires continually expediting the speed of change to build momentum behind shifts within or across systems. It also entails reorienting those systems around new goals, informed by knowledge of common policy, technology, behavioural feedback and governance system dynamics (Allen and Malekpour 2024).

These rapid changes are necessary because the world is not progressing quickly enough on the sustainability agenda to live within planetary boundaries (Rockström *et al.* 2009; Rockström *et al.* 2013; Rockström *et al.* 2023; Gupta *et al.* 2024). Several reasons exist for why accelerating transformative change is itself urgent, beginning with the fact, as demonstrated throughout the report, that rates of change in key systems are too slow. To illustrate, the rate of decoupling economic development from energy consumption needs to more than double (Marques *et al.* 2018).

A related reason for acceleration is the increasing costs of maintaining the status quo. Delays in altering GHG emission trajectories increase the likelihood of temperature increases, intense storms and other effects that can cross tipping points and jeopardize the achievement of targets in the SDGs Framework, the Paris Agreement or the Kunming-Montreal Global Biodiversity Framework (United Nations 2023). By expediting transformative changes, the world will not only reduce the magnitude of potential adverse effects but also save resources and build resilience to the global environmental crises (Jaffee *et al.* 2018). Simply stated, a sustainable future requires a swift and sustainable transformation of systems.

21.5.2 Toward a multidimensional transformation

While there is a need to transform quickly, a sustainable transformation is likely to fail if it focuses on speed only. Rather, efforts are required to accelerate change, increasing the pace of progress on multiple dimensions of sustainability (Pattberg and Bäckstrand 2023). A narrow focus on rapid change may lead to hasty decisions with unintended consequences that undermine support for the changes across different scales, social segments and agents of change (Rosa 2003; Bardin *et al.* 2008; Colvile 2016; Beck and Rosa 2022). This subsection examines these additional dimensions, starting with space and scale.

Transformation must operate at multiple scales: local, regional, and global. Focusing on scale will help anchor sustainability initiatives in the surrounding context and offer opportunities for spreading success. As underlined in the co-production discussion in this chapter, considering context is imperative because what constitutes a sustainable transformation is relative (Rockström *et al.* 2013). Different parts of the world will have varying starting, entry, and end points, as well as different priorities, resources, and enabling environments (Southern and Jones 2004; Gerk and Qassim 2008).

A second dimension of transformation involves working across sectors and systems. Much like working across levels and scales, a deliberate effort is required to align the interests in key sectors such as economy, energy, and food. Sectoral integration is necessary to avoid fragmented efforts that give rise to inefficiencies, trade-offs or bureaucratic conflicts (Berg 2022).

A third dimension of a sustainable transformation involves different social segments and agents of change. In this context, political and social inclusion merit attention as a policy that accelerates renewable energy adoption could have adverse impacts on communities dependent on fossil fuels. Including distinct segments of society and agents of change as part of a just transition is thus essential, as the notion of transformation might mean different things to different agents of change (Trask 2009; Kuschel *et al.* 2017).

A fourth dimension of transformation pertains to the depth of change. Many of the challenges to a sustainable transformation are not related to deeply held values and ontologies. Changes to these values, goals and paradigms (IPBES 2022), as well as the expansion and spread of participatory, emancipatory and pluralist processes, are needed for a transformation to be sustainable (Scoones *et al.* 2020).

In sum, accelerating transformation is not equivalent to accelerating a sustainable transformation. The latter suggests a more nuanced, multidimensional

Box 21.8: Participatory and inclusive governance reforms that can support a multidimensional transformation

Rapid technological, economic, or societal transformations may generate trade-offs. For example, globalization has resulted in the homogenization of cultural practices, eroding local traditions and languages (Yoo and Yi 2022; Allen et al. 2024). This can lead to identity crises, especially for communities whose heritage is endangered. Societal norms may also be destabilized, as the swift adoption of new technologies and ideas may outpace societal readiness.

Acceleration can result in generational divides, where younger people adopt change more rapidly than older generations, creating tensions within families and communities (Beck and Rosa 2022). Furthermore, rapid shifts in social expectations, such as changes in gender roles or family structures, can cause confusion and resistance among certain groups, leading to social fragmentation and polarization.

It is, however, possible that more inclusive and participatory forms of governance could help limit those trade-offs. For example, public consultations and transparent budgeting processes may be able to address those concerns. Additionally, public-private partnerships in clean energy may help raise revenues, but they also elicit questions about which vendors are being used and at what cost. Here again, efforts to open decision-making processes over vendor selection criteria may help allay those concerns and lower costs or boost product quality.

Finally, disruptive changes to prevailing social structures may lead to social displacement – for instance, the creation of formal waste-management systems may undermine the informal gathering and recycling of materials. In this instance, it will be critical to recognize the role of the informal economy and identify pathways to participate in its steady improvement.

view that is not only about how rapidly or efficiently systems change but also how effectively and equitably they transform. This multidimensional view suggests that the shift may not happen instantaneously or seamlessly but rather entails continuous, nonlinear efforts to restructure systems in line with the six principles of transformation in 12.4. Furthermore, this restructuring needs to occur across multiple scales, spaces, sectors, systems, social segments, and agents of change within a compressed time frame.

21.5.3 Governance for accelerating a sustainable transformation

A question arising from the previous section is how to capitalize on the multidimensionality of that transformation while also driving rapid change. Several disciplines have offered insights into this question. Some branches of economics, for instance, hold that the interplay between socioeconomic and technological advances can contribute to productivity surges or spark swift exponential growth that feeds off itself and builds wider changes in areas such as computing power. The theory of disruptive innovation suggests a process that also builds on itself when new technologies start as niche products but evolve to supplant outdated industries and markets (Christensen *et al.* 2018). Meanwhile, organizational studies contend that institutional agility and forward-thinking leadership are critical to expediting these processes.

Although there is significant potential to catalyse a virtuous cycle of change that supports accelerating a sustainable transformation, political ecology emphasizes that these optimistic narratives often underplay the critical role of power relations and economic structures that shape and drive environmental transformations. This political ecology view suggests that environmental degradation and the uneven distribution of resources are not simply technical challenges but are deeply embedded in broader political and economic processes. Such processes prioritize short-term economic growth over long-term environmental and social sustainability, perpetuating inequalities in resource access and environmental risks (Robbins 2019; Buzarovski 2022).

Credit: Image-Source/Envato

Given these constraints, governance and institutional reforms can serve as crucial components in fostering and sustaining momentum for change. Some governance reforms will be needed to strengthen integration across the processes highlighted in this chapter. For example, governance reforms that enhance connections between participatory forms of co-production, efforts to overcome lock-ins and empower agents of change to leverage motivators can arguably give rise to changes within and across systems. This may entail making stronger links between co-production, barriers analyses, and empowerment of key agents in climate, biodiversity, pollution and other planning processes. Strengthening the interface between these three processes can create self-reinforcing loops, mirroring what political ecology describes as the recursive relationship between environmental degradation and sociopolitical processes. As pathways become more aligned with the context, lock-ins will break faster, and motivators will achieve greater results. This cyclical interaction accelerates the pace of transformation, creating opportunities for faster yet sustainable progress across various dimensions of change.

While greater integration across processes is essential, governance reforms can also help alter the structures that entrench political-economic systems. More specifically, the multisectoral and multilevel forms of governance that break down the siloed structures and related thinking, preventing transformative processes from moving forward. Silos and sectoral divisions often mirror deeper power dynamics that hinder coordinated responses to environmental challenges (Peet and Watts 2004). To a significant extent, this necessitates reforms that generate opportunities for agencies with different remits to work together as part of a whole-of-government approach. For instance, economic, social welfare and environmental ministries can be motivated to find synergies and enhance coherence across portfolios or interests in healthcare, land use and climate policies (Zusman and Amanuma 2018).

At the same time, there is also a critical vertical or multilevel dimension to reforming governance structures. Enhancing vertical integration in governance and policy implementation can involve harmonizing reporting protocols from the global to grassroots levels, ensuring consistency, accountability, and effective data flow for informed decision-making, improved resource allocation, and alignment with overarching sustainability goals. It may also involve providing cities with planning tools to craft innovative solutions to climate and other sustainability challenges. Finally, enhancing vertical or multilevel governance can involve creating fiscal incentives – direct resource transfers or tax incentives – to bring innovative solutions to scale for those challenges.

While multisectoral and multilevel reforms can help break down silos, they may not necessarily promote inclusion and social justice. Inclusion as part of an effort to promote democratizing environmental decision-making can help address structural barriers to transformation (Peet and Watts 2004). Inclusive governance reforms can consist of

targeted techniques familiar to those working on just transitions that limit job losses and dislocation. Further, as discussed and illustrated by examples in **Box 21.8**, such reforms may also limit trade-offs that accompany rapid transformations.

In addition to limiting trade-offs, more inclusive forms of governance can empower and harness the power-interest dynamics of different agents of change. Enabling meaningful participation can bring in overlooked agents who could be natural allies in the drive for a sustainable future. This may involve promoting participation in line with provisions of the Aarhus Convention on Access to Information, Public Participation, and Access to Justice in Environmental Matters (Council of the European Union 2005). It could also entail efforts to enhance youth participation in the Voluntary National Reviews of the SDGs (Fukuda and Zusman 2024). The emergence of climate assemblies in some cities, which enable deliberation over public budgets in relation to sectoral targets, can similarly empower citizen groups to help shape transformations (Gillespie *et al.* 2013; Elstub *et al.* 2021).

Beyond empowering and enabling agents of change, inclusion can also help recognize sustainability solutions that already exist. This is particularly relevant when it comes to Indigenous Peoples who have often performed well on measures of sustainability such as rates of biodiversity loss (IPBES 2019). Many Indigenous Peoples recognize the intrinsic values of nature and may be more attuned to crafting nature-based solutions (IPBES 2022). Ensuring Indigenous Peoples have the opportunities and rights to manage their lands and share those experiences can also ensure that Indigenous ontologies and practices inform and inspire transformations (UNEP and ISC 2024). This inclusion may be particularly important for climate adaptation as it often entails integrating diverse forms of knowledge – mitigation, adaptation, and resilience-building – to address the global environmental crises (Bhandari 2024).

A final reason that efforts to move fast should also be inclusive involves complementarities between different dimensions of a transformation. Participation and inclusion can move forms of governance from a whole-of-government to a whole-of-society approach. Inclusion and participation can also bring inputs and resources from non-governmental organizations, businesses, academic institutions, and community representatives that help align the interests of government agencies (O'Brien *et al.* 2021; Paskaleva *et al.* 2015). Hence, framing the transformation as a win-win model, while highlighting the costs of inaction for all actors across different time periods, is essential to a multidimensional transformation.

21.6 Concluding thoughts

This chapter has argued that accelerating a sustainable transformation is both urgently needed and eminently possible. Making it possible requires taking tangible action that can contribute to three processes – the co-production of pathways, the removal of lock-ins, and the empowerment of agents of change – that can expedite the pace of transformation. Those actions range from efforts to transform food systems with clear policy directions, adequate financing, and institutional support in many parts of Latin America, to combinations of actions aimed at transforming energy systems in several parts of China. These actions are likely to be most successful when agents of change with varying levels of interest and power expand the opportunities for change. They are also most likely to succeed when governance arrangements align the interests of government agencies and agents of change as part of a whole-of-government and whole-of-society approach to a multidimensional transformation.

Plurilateral alliances of like-minded countries, or so-called 'coalitions of the willing', can play a crucial role in accelerating transformations to sustainability by enabling ambitious action beyond the pace of global consensus. These coalitions, whether they focus on energy, food, or material/waste systems, or transformation of economic and financial systems, allow members to coordinate policies, share technology and best practices, and pool resources to achieve scale and impact more quickly. By setting high standards and demonstrating viable pathways, they create momentum that can influence global norms and markets, encourage lagging countries to follow suit. Plurilateral cooperation offers a pragmatic route to speed up progress while keeping the door open for broader inclusion and multilateral UN level actions over time.

Annex 1 Global Environmental Crises Diagram

1. Illustration of interacting crises

We introduce a stylised figure to illustrate how different pressures contribute to each crisis and the potential interlinkages between crises (**Figure A1.1**).

Each environmental crisis can be defined along multiple axes and is subject to, and emerges from, various pressures. The interactions (arrows; Figure A1.1a) between some crises are stronger than between other crises, with arrow width indicative of interaction strength (low, medium and high). Depth of shading reflects the qualitative assessment of confidence in the assigned interaction strengths (well established, established but incomplete, unresolved, and inconclusive). Pressures (Figure A1.1b) are as defined in Chapter 2: (1) Land use change represents the conversion from one land use type to another, with the most prevalent land use transitions occurring between cropland and forest; (2) Resource use/exploitation considers multiple resources, including exploitation of fish and wildlife, fossil fuels, minerals and rare elements, wood and timber, and water extraction; (3) Emissions encompass greenhouse gases and other pollutants, including short-lived climate pollutants, such as black carbon, and chemical pollutants from industry and agriculture; (4) Invasive alien species are defined as species introduced to areas outside their native range that have become successfully established and cause substantial impacts on the new environment. The relative contribution (low, medium and high) of pressures to the different crises is indicated by the histograms, with depth of shading reflecting the qualitative assessment of confidence in the assigned contribution weights (well established, established but incomplete, unresolved, and inconclusive).

Figure A1.1: **The interconnected global environmental crises of climate change, biodiversity loss, land degradation and desertification, and pollution and waste**

1. Illustration of interacting crises

We introduce a stylised figure to illustrate how different pressures contribute to each crisis and the potential interlinkages between crises (**Figure A1.1**).

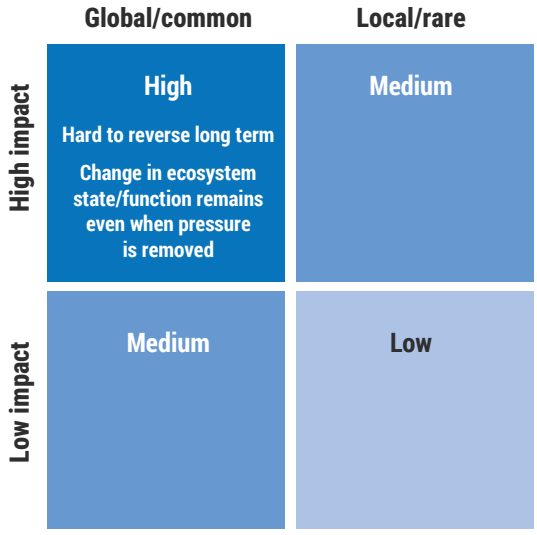
Each environmental crisis can be defined along multiple axes and is subject to, and emerges from, various pressures. The interactions (arrows; Figure A1.1a) between some crises are stronger than between other crises, with arrow width indicative of interaction strength (low, medium and high). Depth of shading reflects the qualitative assessment of confidence in the assigned interaction strengths (well established, established but incomplete, unresolved, and inconclusive). Pressures (Figure A1.1b) are as defined in Chapter 2: (1) Land use change represents the conversion from one land use type to another, with the most prevalent land use transitions occurring between cropland and forest; (2) Resource use/exploitation considers multiple resources, including exploitation of fish and wildlife, fossil fuels, minerals and rare elements, wood and timber, and water extraction; (3) Emissions encompass greenhouse gases and other pollutants, including short-lived climate pollutants, such as black carbon, and chemical pollutants from industry and agriculture; (4) Invasive alien species are defined as species introduced to areas outside their native range that have become successfully established and cause substantial impacts on the new environment. The relative contribution (low, medium and high) of pressures to the different crises is indicated by the histograms, with depth of shading reflecting the qualitative assessment of confidence in the assigned contribution weights (well established, established but incomplete, unresolved, and inconclusive).

2. Process for deriving qualitative estimates of the contribution of pressures to crises and interaction strengths among crises, along with confidence levels

In part (a) the direction of each arrow reflects the path of causality. Arrow width indicates the comparative strength of interactions between the crises, indexed on an ordinal scale: low, medium and high. For example, in the illustration above, pollution has a medium impact on biodiversity, but biodiversity has a low impact on pollution.

In part (b) the relative contribution weights of pressures are qualitative and follow the same ordinal scale adopted for interaction strengths (i.e., low, medium and high). Pressure contributions broadly consider both the impact of the pressure on the crisis and the spatio-temporal scale over which pressures are experienced (**Figure A1.2**). Weights reflect the direct effect of the pressure on the crisis, for example, the effect of emissions on biodiversity is largely through their effects on climate chanage; thus the contribution weight of emssions on biodiversity is low, but the interaction strength between climate change and biodiversity is high.

Weights assigned to arrows and pressures reflect the views of the GEO subject matter experts and are not intended to represent a formal evaluation of the literature or data analysis, which is beyond the remit of the GEO assessment process (see Procedure for GEO expert consultation; **Figure A1.3**).



The different shading for both arrows and histograms indicates the level of confidence in weights assigned by GEO subject matter experts and represents their knowledge of the scientific literature, following the qualitative assessment guidelines detailed in the GEO Intergovernmental and Expert-led Scientific Assessment Procedures guidelines. Confidence statements are classified as: well-established, established but incomplete, unresolved, and inconclusive.

We provide fully referenced examples of the potential pairwise interactions between crises in the global environmental crises Chapeau (**Table C.1-C.6**), demonstrating how each crisis is multifaceted and can thus be described along many possible axes. In some cases, our knowledge of the impacts of interactions between crises may be data-limited or full impacts may only become apparent in the future; this adds to uncertainty in the assigned weights and may be captured in the confidence statements. Importantly, interaction strengths between crises can also vary by temporal or spatial scale and between regions and ecosystems. For example, island nations will be disproportionately impacted by climate change–mainly through sea level rise and increasing frequency of storm events. Thus, solution pathways need to be region-specific.

We recognise that the pairwise interaction structure shown in **Figure A1.1** is overly simplistic and that

the crises are all interconnected spatially, temporally and causally. The pairwise connections between crises can also form longer chains of interactions that may include complex feedbacks, challenging simple extrapolations (Pfenning-Butterworth et al. 2024). While we do not attempt to capture these added complexities here, as doing so would inevitably reduce interpretability, they should be considered when identifying solution pathways.

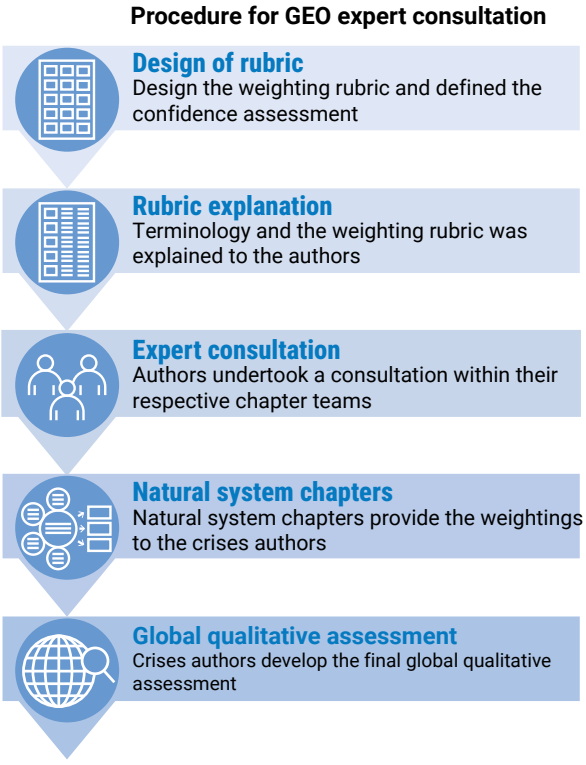


Figure A1.2: Guide to assist with the qualitative assesment of the contribution of pressures to crises

Impacts of pressures on crises were defined as high impact (top row) if they result in crisis-induced changes in the natural system (i.e., ecosystem state or function) that are hard to reverse and/or long term such that changes in the natural system remain even when the pressure is removed. Low impact pressures (bottom row) are pressures not classified as high impact (i.e., impacts on crisis-induced change to the natural system are easy to reverse and/or short-term such that changes in the natural system are not sustained when the pressure is removed). Pressure weights (quadrats) reflect both impacts of pressures and their spatiotemporal scale. With higher weights assigned to pressures that occur over larger geographical extents and/or with greater frequency.

The contribution weight (histograms, **Figure A1.1b**) of a pressure was indexed as high if the pressure was assessed as high impact and was spatially widespread/global and/or temporally frequent/common (**Figure A1.2** top left). The contribution weight of a pressure to a crisis was indexed as low if the pressure was assessed as low impact and was spatially restricted/local and/or temporally infrequent (**Figure A1.2** bottom right). A pressure that did not meet criteria for high or low, was indexed as medium (Figure A1.2 top right and bottom left).

Figure A1.3: Procedure for GEO expert consultation

Annex 2 General information on the inclusion of Indigenous Knowledge and Local Knowledge in the Seventh Global Environment Outlook (GEO-7)

Introduction

During the Scoping Meeting held in October 2022, Member States requested that Indigenous Knowledge and Local Knowledge (IK & LK) should be incorporated into the GEO assessment. The scoping document stated that GEO-7 should build on information from diverse credible data sources, including Indigenous Knowledge, and where possible local knowledge. In order to fulfill this request, GEO-7 has, for the first time, systematically drawn upon IK & LK and addressed issues related to Indigenous Peoples. This was done through the following mechanisms:

1. **The IK & LK Task Force**: A group of Indigenous and non-Indigenous experts who guided the process of including IK & LK into GEO-7 in collaboration with the Co-Chairs and contributed to the text as Lead Authors and Fellows.

2. **The inclusion of IK & LK related issues in the text**: This content was included in all the chapters, as well as in five IK & LK chapeaus - one for each of report's sections. It was also included in a dedicated section in the Executive Summary and throughout its messages where appropriate.

3. **The IK & LK Dialogues**: Four dialogues with representatives from Indigenous Peoples and local communities were held as part of the process. In addition to the existing literature, the Outcome report of these dialogues represents the key reference for the IK & LK related content in the report.

The Indigenous Knowledge and Local Knowledge Task Force

The IK & LK task force was formed in May 2023. It initially consisted of 10 Indigenous and non-Indigenous researchers and knowledge holders selected from the nominations to the GEO-7 process and was led by two co-convenors who were appointed by the Co-Chairs among its members. A gap-filling exercise took place in January 2024 and the members of the task force increased to 17 with 2 fellows providing support to the process, of whom 12 identify as Indigenous or representatives of a local community. The taskforce was balanced in terms of gender and geographical representation, with only the Eastern Europe not being represented (**Table A2.1**).

Besides overseeing the overall process of including IK & LK into the GEO-7 report, the IK & LK task force's tasks were to develop and carry out IK & LK methods, to develop an overarching IK&LK narrative, to conduct a series of dialogues with representatives from Indigenous Peoples as well as local communities, to contribute as Lead Authors in different chapters and suggest contributing authors where needed, and to develop cross chapter linkages

The IK & LK task force met regularly online (predominantly bi-weekly), and active communication and regular interaction were maintained throughout the process between the task force, the rest of the authors team, the assessment Co-Chairs, and the Secretariat to ensure coherence and effective collaboration. It met in-person at their first face-to-face meeting in October 2023 and thereafter, engaged with the author teams and Co-chairs remotely and during GEO-7 author meetings. Several IK & LK task force members contributed to the IK & LK Dialogues as facilitators and others were included in the team of authors who drafted and revised the Executive Summary.

Table A2.1: GEO-7 IK & LK Taks Force Members Regional Distribution

UN Region	Male	Female	Total
Africa Group	4	0	4
Western Europe	1	5	6
Eastern Europe	0	0	0
Asia Pacific	3	1	4
Latin America and the Caribbean	1	4	5
	8	10	19

The Inclusion of IK & LK in the Text

Since the IK & LK task force was created after the scoping phase and the definition of the structure and content of the assessment and its chapters, the following approach was adopted to include IK & LK-related content into the GEO-7:

- Full embeddedness into the main body of each chapter and the corresponding chapter summaries, thanks to the work of the task force members as Lead Authors. This ensured that IK & LK could complement the scientific perspectives.
- Five IK & LK chapeaux, present at the beginning of each of the parts of the report, allowing for introduction of specific IK & LK concepts and perspectives and fully written by the IK & LK task force members.
- Content from the chapters' summaries and from the five IK&LK chapeaux informed a dedicated section in the Executive Summary and throughout its messages where appropriate

In order to ensure IK & LK was covered in the GEO-7 report, members of the IK & LK task force were nominated as Lead Authors, at least one per chapter based on their expertise. The content of the IK & LK contribution varied from chapter to chapter as agreed upon by the author teams. Depending on the scope of the chapter, the four types of content included: 1) Indigenous conceptualizations and perspectives, 2) IK & LK on the specific issues discussed in the chapter, 3) impacts or potential impacts of the issues discussed in the chapter on Indigenous Peoples as well as local communities, and 4) potential contributions of IK & LK and of Indigenous Peoples as well as local communities to the proposed solutions pathways. The main sources of knowledge to contribute to the chapters were: 1) existing peer-reviewed and non-peer-reviewed literature, and 2) IK & LK Dialogues Outcome Report. When needed, contributing authors (identifying themselves as IK & LK-holder or not) were invited to fill specific gaps in expertise.

The Indigenous Knowledge and Local Knowledge Dialogues

A total of four IK & LK dialogues were planned during the production and launching of GEO-7 for mobilizing IK & LK data and information for the assessment (see **Table A2.2**). The IK & LK dialogues were set up as a participatory approach that builds upon previous successful experiences of working with Indigenous Peoples as well as local communities to inform global environmental assessments. The methodology for the design of these dialogues were informed by

experiences of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) and of the Panamerican Health Organization (PAHO). The dialogues were facilitated by a team of facilitators from SENDAS Asociacion Civil and by the IK & LK task force members. In addition to the participants, the dialogues were attended by "learners" (MESAG members and in the case of the first dialogues also Coordinating Lead Authors) who listed to the discussions without participating in the exchanges.

The first three dialogues resulted in the GEO-7 IK & LK Dialogue Outcome report, which was published in June 2025 by the facilitation team, the IK & LK task force Members and all the organizations of those who participated. A fourth, final, dialogue is tentatively planned to be held after the release of the GEO-7.

Table A2.2: Overview of the GEO-7 IK & LK Dialogues

Dialogues	Thematic focus	Participants	Meeting Dates	Meeting Location & co-host
First Dialogue	Indigenous perspectives, experiences, challenges, actions and desired futures related to the environment and Indigenous communities	28 IK & LK-holders from Asia-Pacific, Africa, Europe and Latin America; 7 learners.	26-28 March 2024	Virtual
Second Dialogue	IK & LK around some transversal thematic axes of the GEO-7 report.	18 IK & LK-holders from Asia, Africa, America, and especially Latin America; 2 learners.	11-13 June 2024	Oaxaca, Mexico, Universidad Nacional Autónoma de México (UNAM)
Third Dialogue	Review of the Second Order Draft of GEO-7 and the First Order Draft of the Executive Summary.	22 IK & LK-holders from Africa, the Arctic, Asia, Central and South America, North America, and the Pacific; 2 learners.	13-15 January 2025 (preparatory sessions in November and December 2024)	Chiang Mai, Thailand, Asia Indigenous Peoples Pact (AIPP)
Fourth Dialogue	"Giveback" workshop: IK & LK methodology used in GEO-7 and lesson learned for future similar processes.	TBD	January 2026 TBD	Virtual

Annex 3 Qualitative assessment of confidence

Assessments and their Executive Summary include a qualitative assessment of confidence associated with their main findings. The following factors will be considered to evaluate the validity of the message or finding: the type, quantity, quality and consistency of evidence (e.g. the existing peer reviewed literature and grey literature), as well as the level of agreement (the level of concurrence in the data, literature and amongst experts, not just across the author team). The author team's expert judgement on the level of evidence and agreement will then be used to apply a confidence term as described below and in **Figure A3.1**:

(d) Inconclusive – existing as or based on a suggestion or speculation; no or limited evidence. Will typically be used infrequently butis intended to provide authors with the flexibility to emphasize issues that are not established in science but that are important to policymakers or might have been highlighted by a different audience.

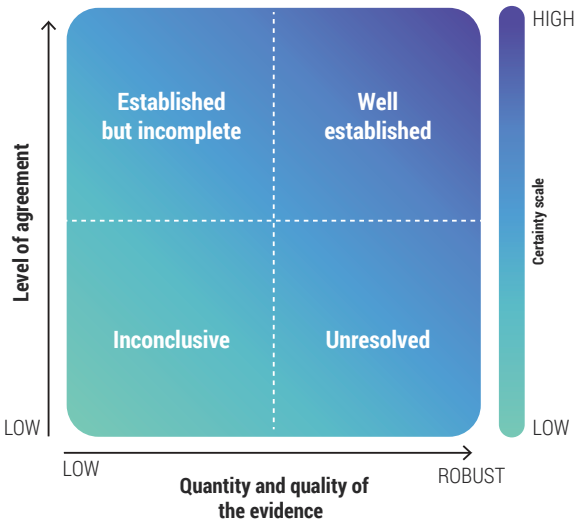
(d) Unresolved – multiple independent studies exist but conclusions do not agree.

(d) Established but incomplete – general agreement although only a limited number of studies exist but with no comprehensive synthesis, or the studies that do exist imprecisely address the question.

(d) Well established – comprehensive meta-analysis or other syntheses/multiple independent studies that agree. The 'well-established' box in **Figure 11.1** may be further subdivided in order to give author teams the flexibility to emphasize key messages and findings that the author team has very high confidence in:

(ii) Very well established – very comprehensive evidence base and very low amount of disagreement.

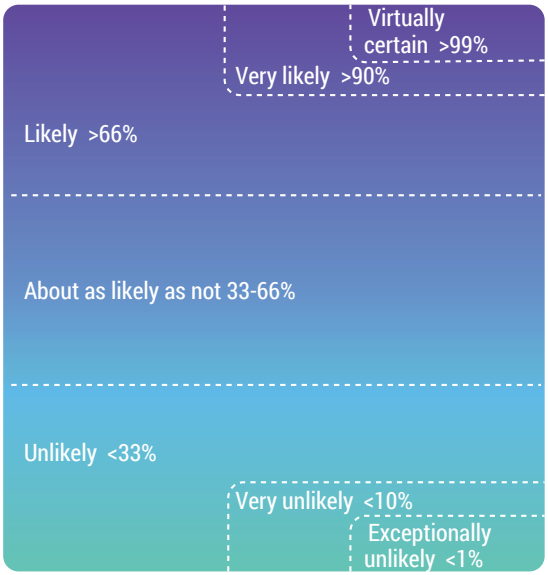
(ii) Virtually certain – very robust data covering multiple temporal and spatial scales and almost no disagreement.



The qualitative confidence terms discussed in this section should not be interpreted probabilistically and are distinct from "statistical significance". The degree of confidence in findings that are conditional on other findings should be evaluated and reported separately.

Quantitative assessment of confidence

Where possible, quantitative assessments of confidence will be communicated as likelihoods. Likelihood expresses a probabilistic estimate of the occurrence of a single event or of an outcome within a given range. Probabilistic estimates are based on statistical analyses of observations or model results, or both, combined with expert judgment.



When sufficient probabilistic information is available, consider ranges of outcomes and their associated probabilities with attention to outcomes of potentially high consequence. The author team's expert judgement on the magnitude of the probability should then be used to apply a likelihood term (see **Figure A3.2**).

Figure A3.1: Qualitative Assessment of Confidence Statements

Categories in **Figure A3.2** can be considered to have nested boundaries. For example, describing an outcome as likely or very likely conveys in both cases that the probability of this outcome could fall within the range of >90% probability. However, in the case of likely, the larger range (66-100%) indicates a higher degree of confidence than very likely (>90%). In making their expert judgement, author teams should start at about as likely as not and consider whether there is sufficient quantitative information available to assign either a likely or unlikely probability range. Only after considering this initial range should the author teams consider whether there is sufficient evidence to move to more extreme levels of probability. Author teams should note that using a likelihood term for a specific outcome implies that alternative outcomes have the inverse likelihood, e.g. if an outcome is likely (a range of >66%) then that would imply that other outcomes are unlikely (<33% probability).

Figure A3.1: Quantitative Assessment of Confidence Statements

Contributors

GEO-7 Author Teams

Assessment Co-chairs: Edgar E. Gutierrez-Espeleta [University of Costa Rica (retired), Costa Rica]; Nyovani Madise [African Institute for Development Policy, Malawi, United Kingdom of Great Britain and Northern Ireland]; Bob Watson [University of East Anglia, United States of America, United Kingdom of Great Britain and Northern Ireland]; Ying Wang [Tongji University, China]

Coordinating Lead Authors of Parts: Ghassem Asrar [Universities Space Research Association (Retired), United States of America]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Diego Martino [Asesoramiento Ambiental Estrategico and Universidad ORT Uruguay, Uruguay]; Fang Yu [Chinese Academy of Environmental Planning, China], Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]

Chapter 1 Introduction

Sofia Belardinelli [University of Padova, Italy]; Leila Dagher [Lebanese American University, Lebanon]; Valerie Nelson [National Resource Institute/University of Greenwich, United Kingdom of Great Britain and Northern Ireland]; Jan Plesnik [Nature Conservancy Agency of the Czech Republic, Czechia]; Maria-Cristina Tirado-von der Pahlen [University of California, Spain]

Chapter 2 Historical, Current, and Projected Drivers and Pressures of Environmental Change

Susana Beatriz Adamo [CIESIN-Climate School-Columbia University, Argentina]; Quosay Awad Ahmed [University of Khartoum, Sudan]; Raphael Villela Almeida [Institute for Applied Economic Research, IPEA, Brazil]; Ricardo O. Barra [University of Concepción, Chile]; Jonathan Davies [University of British Columbia, Canada]; Jagath Premakumara Dickella Gamaralalage [Institute for Global Environmental Strategies, Sri Lanka]; Rozana Himaz [University College London, United Kingdom of Great Britain and Northern Ireland]; Miho Kamei [Institute for Global Environmental Strategies (IGES), Japan]; Jinlong Liu [Renmin University of China, China]; David Lopez-Carr [University of California, United States of America]; Astride Messaga Maffo [Institut de Formation et de Recherche Demographiques, IFORD, Cameroon]; Indu K Murthy [Center for Study of Science, Technology and Policy, India]; Evans Osabuohien [Covenant University/ DePECOS Institutions and Development Research Centre-DIaDeRC, Nigeria]; Jacob Park [University of Johannesburg/ Vermont State University, United States of America]; Chao Ren [The University of Hong Kong, China]; Adina Manuela Relicovschi [European Investment Bank, Romania]; Roopesh Kevin Sungkur [University of Mauritius, Mauritius]; Thomas Thornton [University of Alaska, United States of America]; Chiara Varazzani [Organisation for Economic Cooperation and Development, Australia]; Samanta Villegas [Jocotoco Conservation Foundation, Ecuador]; Le Yu [Tsinghua University, China]

Chapter 3 Air

Nadege Amizero [Environmental Pulse Institute, Rwanda]; Claudio Belis [European Commission, Joint Research Centre, Italy]; Stephan Harrison [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Min Hu [Peking University, China]; Mulako Kabisa [University of the Witwatersrand - Global Change Institute, Zambia]; Indu Murthy [Center for Study of Science, Technology and Polic, India]; Graciela Raga [Instituto de Ciencias de la Atmósfera y Cambio Climático, Universidad Nacional Autónoma de México, Argentina]; Stefan Reis [German Aerospace Centre's Project Management Agency, Unit Environment and Sustainability]; Pallavi Saxena [Department of Environmental Science, Hindu College, University of Delhi, India]; Sotiris Vardoulakis [HEAL Global Research Centre, University of Canberra, Australia]; Carol Zavaleta-Cortijo [Universidad Peruana Cayetano Heredia, Peru]

Chapter 4 Land and Soils

Zoe Barr [Yale School of the Environment, United States of America]; Bhabananda Biswas [Global

Centre for Environmental Remediation, the University of Newcastle and crc for Contamination Assessment and Remediation of the Environment, Australia]; Jonathan Davies [University of British Columbia, Canada]; Jyotsna Krishnakumar [Keystone Foundation, India]; Andrei Kirilenko [University of Florida, Russian Federation]; Lydie-Stella Koutika [Soil Care and Environmental Studies (SCES), Republic of the Congo]; Ravendra Naidu [Global Centre for Environmental Remediation, the University of Newcastle and crc for Contamination Assessment and Remediation of the Environment, Australia]; Leisa Perch [SAEDI Consulting (Barbados) Inc, Barbados]; Xiyan Xu [Chinese Academy of Sciences, China]; Le Yu [Tsinghua University, China]; Pandi Zdruli [International Centre for Advanced Agronomic Mediterranean Studies (CIHEAM) Mediterranean Agronomic Institute of Bari, Albania]

Chapter 5 Oceans and Coast

Fagr Abdel-Gawad [National Research Centre, Egypt]; Salud Deudero Company [Instituto Español de Oceanografia, Spain]; Catia Motta Domingues [National Oceanography Centre, Brazil]; Isa Olalekan Elegbede [Lagos State University, Nigeria]; Pedro Fidelman [Centre for Policy Futures, The University of Queensland, Australia]; Rose Foster [Centre for Policy Futures, The University of Queensland, Australia]; Sandya Gunasekara [Centre for Policy Futures, Sri Lanka]; Britta Denise Hardesty [Commonwealth Scientific and Industrial Research Organisation, United States of America]; Paul Overduin [Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research, Netherlands (Kingdom of the)]; Helen Spence-Jones [Alfred-Wegener-Institute Centre for Polar and Marine Research and Trinity College Dublin, United Kingdom of Great Britain and Northern Ireland]; Karen Helen Wiltshire [Alfred Wegener Institute, Centre for Polar and Marine Research and Trinity College Dublin, Ireland]

Chapter 6 Freshwater

Tamiru A. Abiye [University of the Witwatersrand, Johannesburg, Ethiopia]; Lindsay Beevers [University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Shaneel Chandra [Central Queensland University, Fiji]; Maryam Eqan [Global Youth Biodiversity Network, United Nations Major Group for Children and Youth, Pakistan]; Vinicius F. Farjalla [Federal University of Rio de Janeiro, Brazil]; Erica Brown Gaddis [SWCA Environmental Consultants, United States of America]; Slobodan Gnjato [University of Banja Luka, Bosnia and Herzegovina]; Yolanda López-Maldonado [Indigenous Science, Mexico]

Chapter 7 Implication of Environmental Crises on the Socioeconomic Dimensions of the Sustainable Development Goals

Aliyu Aliyu [University of Lincoln, Nigeria]; Farshad Amiraslani [University of Tehran, Iran (Islamic Republic of)]; Alison Amoussou [United Nations Resident Coordinator Office in UAE, France]; Lindsay Beevers [University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Elliot Boateng [Kwame Nkrumah University of Science and Technology, Ghana]; Mark Elder [Institute for Global Environmental Strategies, United States of America]; Erica Gaddis [SWCA Environmental Consultants, United States of America]; Sandya Gunasekara [Centre for Policy Futures, Sri Lanka]; Maryna Henrysson [Royal Institute of Technology, Sweden]; Saleemul Huq [Late, Bangladesh];Govind Kelkar [GenDev Centre for Research and Innovation, India]; Andrei Kirilenko [University of Florida, Russian Federation]; Mahdi Kolahi [Ferdowsi University of Mashhad, Iran (Islamic Republic of)]; Jyotsna Krishnakumar [Keystone Foundation, India]; Tao Lin [Institute of Urban Environment, Chinese Academy of Sciences, China]; Nomanesi Madikizela-Madiya [University of South Africa, South Africa]; Valerie Nelson [University of Greenwich, United Kingdom of Great Britain and Northern Ireland]; Jaee Nikam [Stockholm Environment Institute, India]; Simon Høiberg Olsen [Institute for Global Environmental Strategies, Denmark]; Iryna Ponedelnik [Independent, Belarus]; Riya Rahiman [Coalition for Disaster Resilient Infrastructure, India]; Savio Rousseau Rozario [International Centre for Climate Change and Development, Bangladesh]; Kamaljit K Sangha [Charles Darwin University, Australia]; Ekaterina Terenteva [Russian Federation, Russian Federation]; Maria Cristina Tirado-von der Pahlen [University of California, SHE Foundation, Spain]

Chapter 8 Interlinkages across Environmental Changes, Scales and Geographic Regions and Subregions

Overall Coordinating Lead Authors: Keisha Garcia (ANSA Merchant Bank Limited), Jeff Seadon (Seadon Consulting)

Kofi Akamani [Southern Illinois University, Carbondale; Ghana]; Adenike Akinsemolu [Afe Babalola University, Nigeria]; Maryam Alkharusi [Independent, Oman]; Tarik Alkharusi [University of Technology and Applied Sciences, Oman]; Francis Boafo Asamoah [International Forestry Students' Association, Ghana]; Janelle Baker [Athabasca University, Canada]; Marianna Baslandze [SOGAZ, Russian Federation]; Lorenzo Benini [European Environment Agency (EEA), Italy]; Suruchi Bhadwal [The Energy and Resources Institute, India]; Gillian Bowser [Colorado State University, United States of America]; Acasia Broomes [Santa Rosa First Peoples Community, Trinidad & Tobago]; Joanne Clarke [Durham University, Australia]; Jan Cools [University of Antwerp, Belgium]; Tatenda Dalu [Stellenbosch, Zimbabwe]; Kenel Delusca [Institute of Technology, Science and Advanced Studies of Haiti, Haiti]; Danielle Mendes Thame Denny [Centre for Advanced Studies in Applied Research, Brazil]; Mark Elder [Institute for Global Environmental Strategies, United States of America]; Eduardo Erazo Acosta [Independent researcher on Indigenous communities, Colombia]; Laura Fanciulli [Italian Ministry of Environment and Energy Security, Italy]; Steven Fletcher [University of Portsmouth, United Kingdom of Great Britain and Northern Ireland]; Keisha Garcia [ANSA Merchant Bank Limited, Trinidad and Tobago]; Elisabeth Gilmore [Carleton University, Canada]; Sarah A. Green [Michigan Technological University, United States of America]; Andres Guhl [Universidad de los Andes, Colombia]; Henry Häkkinen [Zoological Society of London, Finland]; Susie Ho [Monash University, Australia]; Beata Houšková [National Agricultural and Food Centre, Slovakia]; Ekhtekharul Islam [Independent University Bangladesh, Bangladesh]; Efitre Jackson [Makerere University, Uganda]; Qian Jia [Tongji University, China]; Modupe O. Jimoh [University of Warwick, Nigeria]; Mizanur Khan [LDC Universities Consortium on Climate Change (LUCCC), LDC Group, Bangladesh]; Kyung Ah Koo [Korea Environment Institute, Republic of Korea]; Vojtech Kotecky [Charles University Environment Centre, Czechia]; Gabriela Kreutzberger [World Economic Forum, Chile]; Joanna Kulczycka [Mineral and Energy Economy Research Institute, Polish Academy of Sciences, Poland]; Mengxing Li [Monash University, China]; Jianguo Liu [Michigan State University, China]; Melisa Ljusa [University of Sarajevo, Bosnia and Herzegovina]; Clever Mafuta [GRID-Arendal, Zimbabwe]; Troy McGee [Monash University, Australia]; Karina Miglioranza [Universidad Nacional de Mar del Plata, IIMyC-CONICET, Argentina]; Ruben Mnatsakanian [Central European University, Armenia]; Indu K Murthy [Center for Study of Science, Technology and Policy, India]; Didacus Namanya [Government of Uganda, Uganda]; S. Nadia Ouedraogo [UNECA, Burkina Faso]; Leisa Perch [SAEDI Consulting (Barbados) Inc, Barbados]; Ramon Pichs-Madruga [Centre for World Economy Studies, Cuba]; Kamal Kumar Rai [Indigenous Knowledge and Peoples Networks, IPs Society for Wetland Biodiversity Conservation Nepal, Nepal]; Jimena Reyeros Sanchez [Fundación Avina, Mexico]; Jeff Seadon [Seadon Consulting, New Zealand]

Chapter 9 Scenario Methodology: Current Trends and Transformation Pathways

Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Ana Paula Aguiar [INPE, Brazilian Institute for Space Research, Brazil]; Alaa Al Khourdajie [Imperial College London, United Kingdom of Great Britain and Northern Ireland]; Vassilis Daioglou [PBL Netherlands Environmental Assessment Agency, Utrecht University, Greece]; Sibel Eker [International Institute for Applied Systems Analysis, IIASA, Türkiye]; Mariana Guttieres-Paz [United Nations Development Programme, Brazil]; Yolanda López-Maldonado [Indigenous Science, Mexico]; Audrone Telesiene [Kaunas University of Technology, Lithuania]; Pushp Raj Tiwari [University of Hertfordshire, India]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]

Chapter 10 Continuation of Current Trends – Global Implications

Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Alaa Al Khourdajie [Imperial College London, United Kingdom of Great Britain and Northern Ireland]; Rob Alkemade [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Michel Bakkenes [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Ricardo O. Barra [University of Concepcion, Chile]; Lindsay Beevers [University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Claudio Belis [European Commission, Joint Research Centre, Italy]; Arthur Beusen [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of

the)]; Hester Biemans [Wageningen University and Research, Netherlands (Kingdom of the)]; Fiffy Hanisdah Binti Saikim [Universiti Malaysia Sabah, Malaysia]; Edward Byers [International Institute for Applied Systems Analysis, IIASA, Ireland]; Vassilis Daioglou [PBL Netherlands Environmental Assessment Agency, Utrecht University, Greece]; Jonathan Davies [University of British Columbia, Canada]; Jonathan Doelman [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Sibel Eker [International Institute for Applied Systems Analysis, IIASA, Türkiye]; Dulce Flores-Renteria [Center for Research and Advanced Studies of the National Polytechnic Institute, Mexico]; Panagiotis Fragkos [E3 Modelling, Greece]; Dimitris Fragiadakis [E3-Modelling, Greece]; Shinichiro Fujimori [Kyoto University, Japan]; Taylor Hanna [Pardee Institute University of Denver, United States of America]; Stephan Harrison [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Tomoko Hasegawa [Ritsumeikan University, Japan]; Mulako Kabisa [University of the Witwatersrand, Zambia]; Kejun Jiang [Hong Kong University of Science and Technology, China]; Yingying Lu [CSIRO, China]; Yolanda López-Maldonado [Independent Scientist, Mexico]; Jonathan D. Moyer [Pardee Institute University of Denver, Netherlands (Kingdom of the)]; Indu K Murthy [Center for Study of Science, Technology and Policy, India]; Ravendra Naidu [University of Newcastle, Australia]; Yuki Ochi [E-konzal, Japan]; Ken Oshiro [Hokkaido University, Japan]; Leonidas Paroussos [E3 Modelling, Greece]; Michael Ruggeri [University of Oxford, Italy]; Heinz Schandl [CSIRO, Australia]; Elias Symeonakis [Manchester Metropolitan University, Greece]; Natalia Tarasova [D.Mendeleev University of Chemical Technology of Russia, Russian Federation]; Audrone Telesiene [Kaunas University of technology, Lithuania]; Pushp Raj Tiwari [University of Hertfordshire, India]; Kazuaki Tsuchiya [National institute for Environmental Studies, Japan]; Kaj-Ivar van der Wijst [Utrecht University, Netherlands (Kingdom of the)]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Utrecht University, Netherlands (Kingdom of the)]; Laszlo Vreedenburgh [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Michaela Werning [International Institute for Applied Systems Analysis, IIASA, Germany]; Le Yu [Tsinghua University, China]; Carol Zavaleta-Cortijo [Universidad Peruana Cayetano Heredia, Peru]

Chapter 11 Transformation Pathways towards Achieving Global Goals – Global Implications

Ana Paula Aguiar [INPE, Brazilian Institute for Space Research, Brazil]; Alaa Al Khourdajie [Imperial College London, United Kingdom of Great Britain and Northern Ireland]; Rob Alkemade [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Michel Bakkenes [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Lindsay Beevers [The University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Claudio Belis [European Commission, Joint Research Centre, Italy]; Arthur Beusen [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Hester Biemans [Wageningen University, Netherlands (Kingdom of the)]; Edward Byers [International Institute for Applied Systems Analysis, Ireland]; Vassilis Daioglou [PBL Netherlands Environmental Assessment Agency, Utrecht University, Greece]; Jonathan Doelman [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Panagiotis Fragkos [E3-Modelling, Greece]; Dimistris Fragkiadakis [E3 Modelling, Greece]; Shinichiro Fujimori [Kyoto University, Japan]; Taylor Hanna [Pardee Institute University of Denver, United States of America]; Kejun Jiang [Hong Kong University of Science and Technology, China]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Yingying Lu [CSIRO, China]; Yolanda López-Maldonado [Independent Scientist, Mexico]; Stephen Maycock [PBL Netherlands Environmental Assessment Agency, South Africa]; Jonathan Moyer [Pardee Institute University of Denver, Netherlands (Kingdom of the)]; Leonidas Paroussos [E3 Modelling, Greece]; Michael Ruggeri [University of Oxford, Italy]; Heinz Schandl [CSIRO, Australia]; Audrone Telesiene [Kaunas University of technology, Lithuania]; Kaj-Ivar van der Wijst [Utrecht University, Netherlands (Kingdom of the)]; Detlef van Vuuren [PBL Netherlands Environmental Assessment Agency, Utrecht University, Netherlands (Kingdom of the)]; Laszlo Vreedenburgh [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Michaela Werning [International Institute for Applied Systems Analysis, Germany]; Carol Zavaleta-Cortijo [Universidad Peruana Cayetano Heredia, Peru]

Chapter 12 Transforming Systems – Principles and Levers in Action

Leila Devia [Instituto Nacional de Tecnología Industrial, Argentina]; Monica Kerretts-Makau [Thunderbird School of Global Management, Arizona State University, Kenya]; Christian Löwe [German Environment Agency, Germany]; Fanni Moilanen [Finnish Institute of Occupational Health, Finland]; Valerie Nelson [University of Greenwich, United Kingdom of Great Britain and Northern Ireland]; Laura Pereira [University of the Witwatersrand, South Africa]; Fred Steward [University of Westminster, United Kingdom of Great Britain and Northern Ireland]; Bruno Turnheim [Institut National de la Recherche en Agriculture, Alimentation et Environnement, France]

Chapter 13 Methodology for Developing Solution Pathways towards System Transformations

Parfait M. Eloundou-Enyegue [Cornell University, Cameroon]; Zhuang Han [Cornell University, The London School of Economics and Political Science, China]; Julia Hammann [Food and Agriculture Organization of the United Nations, Germany]; Joanna Kámiche Zegarra [Universidad del Pacífico, Peru]; Annamaria Lammel [Université Paris 8 Vincennes-Saint Denis, France]; Aynur Mammadova [University of Padova, Azerbaijan]; Sarah-Lan Mathez-Stiefel [University of Bern, Switzerland]; Claude Mbarga Ella [IFORD, Cameroon]; Thang Nguyen Trung [Institute of Strategy and Policy on Agriculture and Environment, Viet Nam]; Karachepone N. Ninan [Centre for Economics, Environment and Society-CEES, India]; Henri Rueff [Centre for Development and Environment, University of Bern, Switzerland]

Chapter 14 Solution Pathways for the Transformation of Economic and Financial Systems

Sofia Belardinelli [University of Padova, Italy]; David Broadstock [National University of Singapore, United Kingdom of Great Britain and Northern Ireland]; Kelo Uchendu [Students Organising for Sustainability, Nigeria]; Tegan Evans [University of Portsmouth, Centre for Blue Governance, United Kingdom of Great Britain and Northern Ireland]; Pierre Failler [University of Portsmouth, France]; Laura Fanciulli [Italian Ministry of Environment and Energy Security, Italy]; Juliana Subtil Lacerda [European Environment Agency (EEA), Brazil]; Patricia Maccagno [Moreno National University, Argentina]; Ronaldo Seroa Da Motta [State University of Rio de Janeiro, Brazil]; Nkechi Owoo [University of Ghana, Ghana]; Adina Manuela Relicovschi [European Investment Bank, Romania]; Kamaljit K Sangha [Charles Darwin University, Australia]; Stella Tsani [National and Kapodistrian University of Athens, Greece]; Jianhua Xu [Peking University, China]

Chapter 15 Solution Pathways for Transformation towards Circularity

Patrick Schröder [Chatham House, New Zealand]; Apoorva Arya [Circular Innovation Lab, India]; Bonmwa Fwangkwal [African Circular Economy Alliance Secretariat, AfDB, Nigeria]; Sigrid Kusch-Brandt [Ulm University of Applied Sciences, University of Southampton, Germany]; Olena Maslyukivska [National University of Kyiv-Mohyla Academy, University of Vaasa, Ukraine]; Botho Bahumi Motlhanka [Global Green Growth Institute, Botswana]; Kamal Kumar Rai [ITT-Nepal, Indigenous Knowledge and Peoples Network, Nepal]; Arthur Silva [Federal University of Rio de Janeiro, Brazil]; Maria Cristina Tirado-von der Pahlen [University of California, SHE Foundation, Spain]; Ken Webster [Cranfield University, Cambridge Institute for Sustainability Leadership, United Kingdom of Great Britain and Northern Ireland]; Xianlai Zeng [Tsinghua University, China]

Chapter 16 Energy System Transformation Pathways

Aseel Ibrahim Mohammed Abo-Taleb [Global Youth and Sustainability Organization, Yemen]; Adedoyin Adeleke [Green Growth Africa Sustainability Network, Nigeria]; Ayodeji Stephen Adekanbi [HydroGEM Energy Advisory, Nigeria]; Janelle Baker [Athabasca University, Canada]; Loïc De Weerdt [University of Antwerp, Belgium]; Sybil Derrible [University of Illinois Chicago, United States of America]; Sabine Fuss [Potsdam Institute for Climate Impact Research, Germany]; Elisabeth Gilmore [Carleton University, Canada]; Chenmin He [Zhejiang University of Technology, China]; Nandakumar Janardhanan [Institute for Global Environmental Strategies, India]; Peter King [Late, Australia]; Debora Ley [United Nations Economic Commission for Latin America and the Caribbean, Ministry of Environment and Natural Resources of Guatemala, Mexico]; Kevin Nnanye Nwaigwe [Clean Energy Research Centre, University of Botswana, Nigeria]; Daniel Alejandro

Pacheco Rojas [Universidad Nacional Autónoma de Mexico,Mexico]; Ruben Prütz [Potsdam Institute for Climate Impact Research, Germany]; Hareenanden Ramasawmy [University of Mauritius, Mauritius]; Maria Virginia Vilariño [Argentine Business Council for Sustainable Development, Argentina]

Chapter 17 Food Systems Transformation Pathways

Peter Alexander [University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Jessica Fanzo [Columbia University, United States of America]; Michele Fontefrancesco [Università Cattolica del Sacro Cuore, Italy]; Jessica Fuller [GRID-Arendal, United States of America]; Juliana Merçon [Universidad Veracruzana, Brazil]; Katie Noble [University of York, United Kingdom of Great Britian and Northern Ireland]; Alice Odingo [University of Nairobi, Kenya]; Lucia Reisch [University of Cambridge, Germany]; Tek Sapkota [International Maize and Wheat Improvement Center (CIMMYT), Nepal]

Chapter 18 Solution Pathways Enabling a Sustainable and Resilient Environment for Systems Transformation

Adolf Acquaye [Khalifa University of Science and Technology, Ghana]; Alex Godoy-Faundez [Universidad del Desarrollo, Chile]; Olga Illarionova [Lomonosov Moscow State University, Russian Federation]; William Armand Mala [Department of Plant Biology, University of Yaoundé I, Cameroon]; Svetlana Radionova [Natural Resources of the Russian Federation, Russian Federation]; Kalim Shah [University of Delaware, Trinidad and Tobago]; Binaya Raj Shivakoti [Institute for Global Environmental Strategies, Nepal]; Gail Taylor [University College London, United Kingdom of Great Britain and Northern Ireland]; Soham Vaidya [Global Shield Secretariat, India]

Chapter 19 Implications for Different Economic Development Contexts

Alaa Al Khourdajie [Imperial College London, United Kingdom of Great Britain and Northern Ireland]; Steve Arquitt [Millennium Institute, United States of America]; Lynette Cheah [University of the Sunshine Coast, Singapore]; Isa Elegbede [Lagos state university, Nigeria]; Pankaj Kumar [Institute for Global Environmental Strategies, India]; Estee Miltz [Millennium Institute, South Africa]; Heinz Schandl [CSIRO, Australia]

Chapter 20 Regional Dimensions of the Transformative Solutions for the Global Environmental Crises

Overall Coordinating Lead Authors: Lindsay Beevers (The University of Edinburgh), Madhav Bahadur Karki (Centre for Green Economy Development, Nepal)

Sanchit Saran Agarwal [The Energy and Resources Institute (TERI), India]; Barbara Amon [Leibniz Institute for Agricultural Engineering and Bioeconomy, Germany]; Aistė Balžekienė [Kaunas University of Technology, Lithuania]; Aliyu Salisu Barau [Bayero University Kano; Urban Climate Change Research Network (UCCRN), Nigeria]; Lindsay Beevers [The University of Edinburgh, United Kingdom of Great Britain and Northern Ireland]; Meena Bohara [National Young Academy of Nepal, ForestAction Nepal, Nepal]; Souhila Bouilouta [National Economic Social and Environmental Council, Algeria]; Tanya Brodie Rudolph [University of Stellenbosch, South Africa]; Edward Byers [International Institute for Applied Systems Analysis (IIASA), Ireland]; Monday Businge [University of Nairobi, Uganda]; Donovan Campbell [The University of the West Indies, Jamaica]; Shaneel Chandra [Central Queensland University, Fiji]; Kalpana Chaudhari [Shah and anchor Kutchhi engineering college, institute for sustainable development and research (ISDR) , India]; Ruijun Chen [Fuzhou University, China]; Kateřina Černý Pixová [Czech University of Life Sciences Prague, Czechia]; Hancheng Dai [Peking University, China]; Danielle Mendes Thame Denny [University of São Paulo - Research Centre for Greenhouse Gas Innovation and Centre for Carbon Research in Tropical Agriculture]; Peter Edwards [Manaaki Whenua Group, Bioeconomy Science Institute, Wellington, New Zealand]; Alan Feest [University of Bristol, United Kingdom of Great Britain and Northern Ireland]; Michele Fontefrancesco [Università Cattolica del Sacro Cuore, Italy]; Emmanuelle Freitas [Center of Mineral Technology, Brazil]; Gladys Cecilia Hernandez-Pedraza [Centro de Investigaciones de la Economia Mundial (CIEM), Cuba]; Gensuo Jia [Chinese Academy of Sciences, China]; Madhav Bahadur Karki [Centre for Green Economy Development, Nepal]; Shaneica Lester [The University of the West Indies, Jamaica]; Jianguo Liu [Michigan State University, China]; Jinlong Liu [Renmin University of China, China]; William Armand Mala

[Department of Plant Biology, University of Yaoundé I, Cameroon]; Jan Matuštík [University of Chemistry and Technology Prague, Czechia]; Alma Mendoza-Ponce [National Autonomous University of Mexico (UNAM), Mexico]; Amy Molotoks [Stockholm Environment Institute, University of York, United Kingdom of Great Britain and Northern Ireland]; Rachid Mrabet [National Institute of Agricultural Research (INRA), Morocco]; Veronica Mwangi [University of Nairobi, Kenya]; Jiayi Ng [Agency for Science, Technology and Research, Singapore]; Judit Oláh [John von Neumann University Doctoral School of Management and Business Administration, University of Debrecen, Hungary]; Jean Pierre Ometto [National Institute for Space Research (INPE), Brazil]; József Popp [John von Neumann University Doctoral School of Management and Business Administration, Hungary]; Joana Portugal Pereira [Coppe/Federal University of Rio de Janeiro and IST/ULisboa]; Fangxia Shen [Beihang University, China]; George Florin Staicu [Academy for Economic Studies, Bucharest, Romania]; Paul Sutton [University of Denver, United States of America]; Sénankpon Stephane Marcel Tcheton [Global Change Institute of the University of the Witwatersrand, Benin]; Thomas Thornton [University of Alaska, National Academy of Sciences, United States of America]; Leila Zamani [Department of Environment of Iran, Iran (Islamic Republic of)]

Chapter 21 Driving the Transformations

Catalina Turcu [University College London, Romania]; Eric Zusman [Institute for Global Environmental Strategies, United States of America]; Medani Bhandari [Atlantic States Legal Foundation, Nepal]; Sibel Eker [Radboud University/ International Institute for Applied Systems Analysis, Türkiye]; Simone Lucatello [Instituto Mora – SECHITI, Mexico]; Paul Lucas [PBL Netherlands Environmental Assessment Agency, Netherlands (Kingdom of the)]; Valerie Nelson [University of Greenwich, United Kingdom of Great Britain and Northern Ireland]; Martina Rotolo [University College London, Italy]; Audrone Telesiene [Kaunas University of Technology, Lithuania]; Sandra Torrusio [Faculty of Natural Sciences and Museum UNLP, Argentina];

Global Environmental Crises Chapeau

Ricardo O. Barra [University of Concepcion, Chile]; Fiffy Hanisdah Binti Saikim [Universiti Malaysia Sabah; Member of the Young Scientists Network – Academy of Sciences Malaysia, Malaysia]; Jonathan Davies [University of British Columbia, Canada]; Dulce Flores-Renteria [Center for Research and Advanced Studies of the National Polytechnic Institute, Saltillo Unit, Mexico]; Stephan Harrison [University of Exeter, United Kingdom of Great Britain and Northern Ireland]; Mulako Kabisa [University of the Witwatersrand - Global Change Institute, Zambia]; Christina Karakizi [National Technical University of Athens, Greece]; Indu K Murthy [CSTEP; Center for Study of Science, Technology and Policy, India]; Ravendra Naidu [Global Centre for Environmental Remediation, the University of Newcastle and crc for Contamination Assessment and Remediation of the Environment, Australia]; Eleni Sofik [National Technical University of Athens, Greece]; Elias Symeonakis [Manchester Metropolitan University, Greece]; Natalia Tarasova [D.Mendeleev University of Chemical Technology of Russia, Russian Federation]; Maria Cristina Tirado-von der Pahlen [University of California, SHE Foundation, Spain]; Le Yu [Tsinghua University, China]

Indigenous Knowledge and Local Knowledge Task Force and Chapeaux Authors

Janelle Baker [Athabasca University, Canada]; Victoria Del Pilar Chicmana Zapata [Universidad Peruana Cayetano Heredia, Peru]; Isa Elegbede [Lagos state university, Nigeria]; Eduardo Erazo Acosta [Universidad de Nariño, Colombia]; Jyotsna Krishnakumar [Keystone Foundation, India]; Yolanda Lopez-Maldonado [Indigenous Science, Mexico]; Jinlong Liu [Renmin university of China, China]; William Armand Mala [University of Yaoundé I, Cameroon]; Juliana Merçon [Universidad Veracruzana, Brazil]; Didacus Namanya [Ministry of Health, Uganda]; Valerie Nelson [University of Greenwich, United Kingdom of Great Britain and Northern Ireland]; Kamal Kumar Rai [ITT-Nepal, Indigenous Knowledge and Peoples Network, Society for Wetland Biodiversity Conservation, Nepal Indigenous Forum for Biodiversity, Nepal]; Aibek Samakov [University of Central Asia, Kyrgyzstan]; Kamaljit K Sangha [Charles Darwin University, Australia]; Sénankpon Stephane Marcel Tcheton [Global Change Institute of the University of the Witwatersrand, Benin]; Thomas Thornton [University of Alaska, United States of America]; Maria Cristina Tirado-von der Pahlen [University of California, SHE Foundation, Spain]; Sarah-Lan Mathez-Stiefel [Centre for Development and Environment, University of Bern

and Wyss Academy for Nature, University of Bern, Switzerland]; Carol Zavaleta-Cortijo [Universidad Peruana Cayetano Heredia, Indigenous Peoples Observatory Network (IPON), Peru]

Behavioural, Social and Cultural (BSC) Task Group

Aistė Balžekienė [Kaunas University of Technology, Lithuania]; Medani Bhandari [Atlantic States Legal Foundation, Nepal]; Elliot Boateng [Kwame Nkrumah University of Science and Technology, Ghana]; Sibel Eker [International Institute for Applied Systems Analysis, IIASA, Türkiye]; Richard Filcak [European Environmental Agency (EEA), Slovakia]; Razieh Ghayoumi [Biodiversity and Biosafety Group, Research Center for Environment and Sustainable Development, Iran]; Elisabeth Gilmore [Carleton University, Canada]; Alex Godoy-Faundez [Universidad del Desarrollo, Chile]; Mariana Guttieres-Paz [United Nations Development Programme, Brazil]; Julia Hammann [Food and Agriculture Organization of the United Nations, Germany]; Sigrid Kusch-Brandt [Ulm University of Applied Sciences, University of Southampton, Germany]; Annamaria Lammel [Université Paris 8 Vincennes-Saint Denis, France]; Aynur Mammadova [University of Padova, Azerbaijan]; Claude Mbarga Ella [IFORD, Cameroon]; Jaee Nikam [Stockholm Environment Institute, India]; Evans Osabuohien [Covenant University, DePECOS Institutions and Development Research Centre-DIaDeRC, Nigeria]; Leisa Perch [SAEDI Consulting (Barbados) Inc, Barbados]; Dan Poniachik Calderon [Social and Behavioral Change Agency Latam, Chile]; Audrone Telesiene [Kaunas University of Technology, Lithuania]; Catalina Turcu [University College London, Romania]; Chiara Varazzani [Organisation for Economic Cooperation and Development, Australia]; Jianhua Xu [Peking University, China]

Climate Change Adaptation (CCA) Task Group

Medani Bhandari [Atlantic States Legal Foundation, Nepal]; Donovan Campbell [The University of the West Indies, Jamaica]; Jan Cools [University of Antwerp, Belgium]; Bonmwa Fwangkwal [African Circular Economy Alliance Secretariat, AfDB, Nigeria]; Mariana Guttieres-Paz [United Nations Development Programme, Brazil]; Mulako Kabisa [University of the Witwatersrand – Global Change Institute, Zambia]; Miho Kamei [Institute for Global Environmental Strategies (IGES), Japan]; Govind Kelkar [GenDev Centre for Research and Innovation, India]; Debora Ley [United Nations Economic Commission for Latin America and the Caribbean, ECLAC, Ministry of Environment and Natural Resources of Guatemala, Mexico]; Simone Lucatello [Instituto Mora – SECHITI, Mexico]; S. Nadia Ouedraogo [UNECA, Burkina Faso]

Fellows

Aseel Ibrahim Mohammed Abo-Taleb [Global Youth and Sustainability Organization, Yemen]; Ayodeji Stephen Adekanbi [HydroGEM Energy Advisory, Nigeria]; Raphael Villela Almeida [Institute for Applied Economic Research, IPEA, Brazil]; Tarik Alkharusi [Imperial College London, UTAS-Oman, Oman]; Nadege Amizero [Environmental Pulse Institute, Rwanda]; Alison Amoussou [United Nations Resident Coordinator Office in UAE, France]; Francis Boafo Asamoah [International Forestry Students' Association, Ghana]; Zoe Barr [Yale School of the Environment, United States of America]; Marianna Baslandze [SOGAZ, Russia]; Sofia Belardinelli [University of Padova, Italy]; Acasia Broomes [Santa Rosa First Peoples Community, Trinidad & Tobago]; Ruijun Chen [Fuzhou University, China]; Maryam Eqan [Global Youth Biodiversity Network, United Nations Major Group for Children and Youth, Pakistan]; Tegan Evans [University of Portsmouth, Centre for Blue Governance, United Kingdom of Great Britain and Northern Ireland]; Laura Fanciulli [Italian Ministry of Environment and Energy Security, Italy]; Rose Foster [Centre for Policy Futures, The University of Queensland, Australia]; Emmanuelle Freitas [Center of Mineral Technology, Brazil]; Slobodan Gnjato [University of Banja Luka, Bosnia and Herzegovina]; Zhuang Han [Cornell University/The London School of Economics and Political Science, China]; Qian Jia [Tongji University, China]; Christina Karakizi [National Technical University of Athens, Greece]; Gabriela Kreutzberger [World Economic Forum, Chile]; Shaneica Lester [The University of the West Indies, Jamaica]; Astride Messaga Maffo [Institut de Formation et de Recherche Demographiques, IFORD, Cameroon]; Jan Matuštík [University of Chemistry and Technology Prague, Czechia]; Claude Mbarga Ella [IFORD, Cameroon]; Estee Miltz [Millennium Institute, South Africa]; Amy Molotoks [Stockholm Environment Institute, University of York, United Kingdom of Great Britain and Northern Ireland]; Fanni Moilanen [Finnish Institute of Occupational Health, Finland]; Botho Bahumi

Motlhanka [Global Green Growth Institute, Botswana]; Katie Noble [University of York, United Kingdom of Great Britain and Northern Ireland]; Iryna Ponedelnik [Independent, Belarus]; Jimena Reyeros Sanchez [Fundación Avina, Mexico]; Martina Rotolo [University College London, Italy]; Michael Ruggeri [University of Oxford, Italy]; Arthur Silva [Federal University of Rio de Janeiro, Brazil]; Eleni Sofik [National Technical University of Athens, Greece]; Helen Spence-Jones [Alfred-Wegener-Institute Centre for Polar and Marine Research and Trinity College Dublin, United Kingdom of Great Britain and Northern Ireland]; Sénankpon Stephane Marcel Tcheton [Global Change Institute of the University of the Witwatersrand, Benin]; Ekaterina Terenteva [Russian Federation, Russian Federation]; Pushp Raj Tiwari [University of Hertfordshire, India]; Kelo Uchendu [Students Organising for Sustainability, Nigeria]; Soham Vaidya [Global Shield Secretariat, India]; Victoria Del Pilar Chicmana Zapata [Universidad Peruana Cayetano Heredia, Peru]

Intergovernmental and Multi-stakeholder Advisory Group (IMAG)

Arthur Eijs [Ministry of Infrastructure & Water Management, Netherlands (Kingdom of the)]; Anna Mampye [Ministry of Forestry, Fisheries and Environment, South Africa]; Rolenas Baereleo [Department of Environmental protection and Conservation, Vanuatu]; Miroslav Havránek [Czech Environmental Information Agency, Czechia]; Ana Julieta Calvo-Obando [Ministry of Environment and Energy, Costa Rica]; Mohamed Abdelraouf [Gulf Research Center (GRC), Egypt]; Thuraya Said Al Sariri [President office- Environment Authority, Oman]; Zahra Abu Taha [ZATARI refugees camp, Oxfam, Jordan]; Silvio Albuquerque e Silva [Embassy of Brazil in Kenya, Brazil]; Djatougbe Aziaka [Welfare Togo, Togo]; Leila Bendifallah [M' hamed Bougara University, Algeria]; Thomas Chali [United Republic of Tanzania]; Merylene Chitharai [UKZN Howard College, South Africa]; Ingrid Coetzee [ICLEI Africa, South Africa]; Alexandra Gurgel Valente da Costa [Ministry of the Environment and Climate Change, Brazil]; Lisa Eriksson [Department for Outlook and Policy, Sweden]; Toghrul Feyziyev [Ministry of Ecology and Natural Resources, Azerbaijan]; Marek Haliniak [Ministry of Climate and Environment, Poland]; Meri Harutyunyan [Ministry of Environment, Armenia]; Neyra Herrera [Ministry of Environment, Panama]; Keri Holland [U.S. Department of State, United States of America]; Yi Huang [Peking University, China]; Claudia Kabel [German Environment Agency (UBA), Germany]; Christina Komorski [Environment and Climate Change Canada, Canada]; Maha Maayta [Ministry of Environment, Jordan]; Takashi Otsuka [Institute for Global Environmental Strategies (IGES), Japan]; Toral Patel-Weynand [U.S. Department of Agriculture Forest Service, United States of America]; Dušica Pešević [University of Banja Luka, Bosnia and Herzegovina]; Salla Rantala [Environmental Policy Centre, Finnish Environment Institute (SYKE), Finland]; Kenset Amaury Rosales Riveiro [Ministry of Environment and Resources Natural Resources (MARN), Guatemala]; Modibo Sacko [Permanent Interstate Committee for Drought Control in the Sahel (CONACILSS), Mali]; Jerome Lugumira Sebadduka [National Environment Management Authority (NEMA), Uganda]; Ruth Viola Spencer [Marine Ecosystems Protected Areas (MEPA) Trust, Antigua and Barbuda]; Gillian Stanislaus [Environmental Management Authority (EMA), Trinidad and Tobago]; Jan-Gustav Strandenaes [University of Stockholm, Norway]; Prem Singh Tharu [Asia Indigenous Peoples Pact (AIPP) under Environment Programme, Thailand]; Alexandra Gurgel Valente da Costa [Ministry of the Environment and Climate Change, Brazil]; Carlos Cordero Vega [Ministry of Environment and Energy, Costa Rica]; Fabian Wagner [IIASA, Germany]; Dominic Kailash Nath Waughray [CEO World Business Council for Sustainable Development, India]

Multidisciplinary Expert Scientific Advisory Group (MESAG)

Nicholas King [Wilderness Foundation Africa, South Africa]; Maria del Mar Viana Rodriguez [Spanish Ministry for the Ecological Transition and Demographic Challenge, Spain]; Ervin Balázs [Centre for Agricultural Research of the Hungarian Academy of Sciences, Hungary]; Rosemarie Casimiro [Nueva Ecija University of Science and Technology, Philippines]; Gian Carlo Delgado-Ramos [Institute of Geography, National Autonomous University of Mexico, Mexico] Dolors Armenteras Pascual [Universidad Nacional de Colombia, Colombia]; Ousséni Arouna [National University of Sciences, Technologies, Engineering and Mathematics, Benin]; Lorenzo Ciccarese [Higher Institute for Environmental Protection and Research (ISPRA), Italy]; Sandra Bibiana Correa [Mississippi State University, Colombia]; Eric Davidson [University of Maryland Center for Environmental Science, United States of America]; Nagwa El Karawy [Ministry of Environment (former), Egypt]; Tambe Honourine

Enow [Africa Climate and Environment Foundation (ACEF), Cameroon]; James D. Ford [Priestley Centre for Climate Futures, United Kingdom of Great Britain and Northern Ireland]; Catherine Ganzleben [European Environmental Agency (EEA), United Kingdom of Great Britain and Northern Ireland]; Razieh Ghayoumi [Research Center for Environment and Sustainable Development, Department of Environment, Iran (Islamic Republic of)]; Joyeeta Gupta [University of Amsterdam and IHE-Delft Institute for Water Education, Netherlands (Kingdom of the)]; Tatiana Kuznetsova [The Federal Service for Supervision of Natural Resources Management of the Russian Federation, Russian Federation]; Yonglong Lu [Xiamen University, China]; Mónica Moraes R. [Academia Nacional de Ciencias - Bolivia and Universidad Mavor de San Andrés, Bolivia (Plurinational State of)]; Amal Moufarreh [Ministry of Energy Transition and Sustainable Development, Morocco]; Janez Potocnik [UNEP International Resource Panel, Slovenia]; Nijavalli Ravindranath [Center for Sustainable Technologies, India]; Alberto Santos Capra [Basel Regional Center for South America under the Presidency of the National Institute of Industrial Technology (INTI), Argentina]; Majid Shafie pour Motlagh [University of Tehran, Iran (Islamic Republic of)]; Belay Simane [Addis Ababa University, Ethiopia]; Asha Singh [Environmental Governance Consulting, Guyana]; Inna Stecenko [Transport and Telecommunication Institute, Latvia]; Shau Hwai Aileen Tan [UNESCO-IOC Sub-Commission for Western Pacific (WESTPAC), University Sains Malaysia, Malaysia]; Alban Thomas [INRAE – French National Research Institute for Agriculture, Food and Environment, France]

Review Editors

Ahmed Abdelrehim [retired, formerly CEDARE, Egypt]; Bettina Hedden- Dunkhorst [Bundesamt für Naturschutz (BfN) Federal Agency for Nature Conservation, Germany]; Kofi Akamani [Southern Illinois University, Ghana]; Ramia Al Bakain [The University of Jordan, Jordan]; Chandani Appadoo [University of Mauritius, Mauritius]; Amanullah Bahriuloom [The University of Agriculture Peshawar, Pakistan]; William Balée [Tulane University, United States of America]; Suruchi Bhadwal [The Energy and Resources Institute, India]; Miranda Boettcher [German Institute for International and Security Affairs (SWP), Australia]; Ashok Das [SunMoksha, United States of America]; Naa Dodua Dodoo [African Institute for Development Policy, Ghana]; Oswaldo dos Santos Lucon [Secretary of Infrastructure and Environment Environment of the State of São Paulo, Brazil]; Timothy Dube [University of the Western Cape, Zimbabwe]; Paul Dumble [Independent Climate, Land, Waste and Environment Expert, United Kingdom of the Great Britain and Northern Ireland]; Samia Elfitouri Grimida [Food and Agriculture Organization, Libya]; Miguel Equihua [Institute of Ecology, Mexico]; Gabriela Fernandez [San Diego State University, United States of America]; Elsa Galarza [Pacific University, Research Center, Peru]; Nadezhda Gaponenko [Russian Academy of Sciences, Russian Federation]; Konstantin Gongalsky [A.N. Severtsov Institute of Ecology and Evolution, Russian Federation]; Wame Lucretia Hambira [Botswana University of Agriculture and Natural Resources. Botswana]; Shan Hu [Tsinghua University, China]; Arnulf Jaeger- Waldau [European Commission, Germany]; Rumiana Jeleva [Bulgarian Academy of Sciences, Bulgaria]; Injy Johnstone [Oxford Sustainable Finance Group, New Zealand]; Joni Jupesta [United Nations University, Indonesia]; Lian Pin Koh [National University of Singapore, Singapore]; Anil Markandya [Basque Centre for Climate Change, Spain]; David McCollum [Oak Ridge National Laboratory, United States of America]; Nibedita Mukherjee [Brunel University London, India]; Adetoun Mustapha [Shell Petroleum Development Company of Nigeria Ltd, Nigeria]; Alick Bulala Muvundika [National Institute for Scientific and Industrial Research (NISIR), Zambia]; Leonard Nurse [Centre for Resource Management and Environmental Studies, Barbados]; Eni Oko [Newcastle University, United Kingdom of the Great Britain and Northern Ireland]; Robert Onyeneke [Alex Ekwueme Federal University Ndufu-Alike, Nigeria]; Jiesper Pedersen [Copenhagen Business School, Denmark]; Dimitris Poursanidis [TerraSolutions Marine Environment research, Greece]; Kálmán László Rajkai [Institute for Soil Sciences Centre for Agricultural Research, Hungary]; Kilaparti Ramakrishna [Woods Hole Oceanographic Institution, United States of America]; Abdulkarim Rashed [RRC – London , Dubai branch, Bahrain]; Ariana Rossen [National Water Institute, Argentina]; Mayar Sabet [CEDARE, Egypt]; Georg Schiller [Leibniz-Institute of Ecological Urban and Regional Development, Germany]; Faizi Shahul Hameed [Japan International Coop Agency, India]; Diogo Silva [Federal University of São Carlos (UFSCar), Brazil]; Tannecia Stephenson [The University of the West Indies, Jamaica]; Saritha Sudharmma Vishwanathan [National Institute of

Environmental Studies, India]; Miguel Angel Taboada [Institute of Ecology, Argentina]; Ram Devi Tachamo Shah [Kathmandu University, Nepal]; Goran Trbic [University of Banja Luka, Bosnia and Herzegovina]; Oksana Volosko-Demkiv [Center for Environmental Consulting and Auditing (CECA), Ukraine]; Fei Wang [Chinese Academy of Sciences and Ministry of Water Resources, China]; Sarah Whitmee [London School of Hygiene & Tropical Medicine, United Kingdom of the Great Britain and Northern Ireland]; Lucia Helena Xavier [Mineral Technology Center, Brazil]; Xinzhu Zheng [University of Petroleum, China]; Malgorzata Zimniewska [Institute of Natural Fibers and Medicinal Plants National Research Institute, Poland]

Glossary

Actions and policies
Specified interventions carried out by (an) identified (group of) actor(s) according to their power, authority and competences to influence the operations, performance or configuration of a system or set of practices towards achieving long-term environmental sustainability goals.

Agrivoltaics
An agricultural technique proposed in 1982 that addresses the increasing competition for land between agriculture and renewable solar power installations and has the potential to facilitate the decarbonization of agriculture. The proponents of this approach suggest integrating agriculturalproduction and solar photovoltaic installations in the same area. There are three types of agrivoltaics. Interspersed PV arrays use the space between crop rows to install solar panels. Greenhouse-mounted PV arrays are installed to replace part of the greenhouse cover. Stilt-mounted PV arrays are installed on an open-air structure. These arrays can be static or dynamic. All these techniques rely on the understanding that plants utilize only certain portions of sunlight for growth and that there is a natural point of light saturation wherephotosynthesis levels off and no longer increases. Agrivoltaics can also be used to combine energy production with animal husbandry, potentially improving several aspects, such as providing shade for animal welfare. This concept is also known as agrophotovoltaics, agroPV, solar sharing or PV agriculture.

Agroecology
Agroecology applies ecological and social principles to create sustainable, resilient and equitable food systems.

Alternative proteins
Protein-rich foods that can substitute animal-sourced foods, including plant-based products, fermentation-derived products and cultivated meat.

Anthropogenic
This term denotes circumstances of, related to, or resulting from the influence of human beings on nature.

Bioaccumulation of pollutants
Bioaccumulation refers to the gradual build-up over a period of time of a chemical in an organism's body. When an organism absorbs a substance - in this case, a pollutant - from a medium such as water, that pollutant is then distributed throughout the organism's system. Predators that consume these organisms can receive the pollutants as well. The phenomena can cause significant environmental health risks. A variety of different pollutants commonly cause problems with bioaccumulation.

Biochar
Relatively stable, carbon-rich, charcoal-like material produced by heating biomass in an oxygen-limited environment. The main difference between biochar and charcoal lies in the purpose. Biochar is used as a soil amendment to improve soil functions rather than as a fuel for cooking and heating. In addition, biochar effectively locks away carbon that would otherwise be released as organic matter decomposes through the carbon cycle, making it a form of carbon sequestration. This technique was used by Indigenous communities of the Amazon for centuries.

Biocultural
Biocultural refers to the interwoven relationship between biology and culture, especially within the context of human beings. It encompasses how biology influences culture and vice versa, shaping human societies and their interactions with the environment. This approach is used in various fields like anthropology, sociology, and conservation to understand complex systems where biological and cultural aspects are intertwined.

Biodiversity
The variability among living organisms from all sources including, inter alia, terrestrial, marine and other aquatic ecosystems and the ecological complexes

of which they are part; this includes diversity within species, between species and of ecosystems.

Biodiversity loss
The reduction in the variety and abundance of life on Earth, encompassing genetic, species and ecosystem levels. This decline reflects a reduction in nature's functional capacity to deliver ecosystem services, such as pollination, climate regulation, water purification and nutrient cycling.

Bioeconomy
The bioeconomy is the production, utilization, conservation, and regeneration of biological resources, including related knowledge, science, technology, and innovation, to provide sustainable solutions (information, products, processes and services) within and across all economic sectors and enable a transformation to a sustainable economy.

Blended finance
Blended finance is the strategic combination of public, private, and philanthropic capital to mobilize additional investment for sustainable development projects. By blending different types of capital, blended finance aims to address market failures and create opportunities for private investors to support social and environmental goals.

Blockchain
A particular type of a distributed ledger comprised of unchangeable, digitally recorded data in packages called blocks. A block records some or all of the most recent transactions that have not yet entered any prior blocks. Each time a block is completed, it gives way to the next block in the blockchain. A block is thus a permanent store of records which, once written, cannot be altered or removed.

Blue carbon
Biologically driven carbon fluxes and storage in marine systems that are amenable to management. Coastal blue carbon focuses on rooted vegetation in the coastal zone, such as tidal marshes, mangroves and seagrasses. These ecosystems have high carbon burial rates on a per unit area basis and accumulate carbon in surrounding soils and sediments. They provide many non-climate benefits and can contribute to ecosystem-based adaptation. If degraded or lost, coastal blue carbon ecosystems are likely to release most of their carbon back to the atmosphere. There is ongoing debate about applying the blue carbon concept to other coastal and non-coastal processes and ecosystems, including the open ocean.

Blue economy
Sustainable and equitable use of ocean and coastal resources to support economic and societal wellbeing.

Business model
Describes how a company does business. It is the translation of strategic issues, such as strategic positioning and strategic goals into a conceptual model that explicitly states how the business functions. The business model serves as a building plan that allows designing and realizing the business structure and systems that constitute the company.

Capital
Resource that can be mobilized in the pursuit of an individual's goals. Thus, natural capital (natural resources such as land and water), physical capital (technology and artefacts), social capital (social relationships, networks and ties), financial capital (money in a bank, loans and credit), human capital (education and skills).

Capital market
Capital Markets allow businesses to raise long-term funds by providing a market for securities, both through debt and equity. Capital Markets offer a whole range of sometimes complicated products which allow businesses and banks not just to raise capital but also to hedge (or protect) against risks.

Carbon Dioxide Removal (CDR)
Anthropogenic activities that remove CO_2 directly from the atmosphere and durably store it in geological, terrestrial or ocean reservoirs, or in products; excludes natural uptake not directly caused by human activities.

Carbon market
A trading system through which countries and other actors (i.e. private actors) may buy or sell units of greenhouse-gas emissions in an effort to meet their national limits on emissions, either under the Kyoto Protocol or under other

agreements, such as that among member states of the European Union.

Carbon offset

Any activity that compensates for the emission of CO_2 or other greenhouse gases (measured in CO_2e) by providing for an emission reduction elsewhere. Because greenhouse gases are widespread in Earth's atmosphere the climate benefits from emission reductions regardless of where such cutbacks occur. If carbon reductions are equivalent to the total carbon footprint of an activity, then the activity is said to be carbon neutral. Carbon offsets can be bought, sold, or traded as part of a carbon market.

Carbon pricing

Initiatives that put an explicit price on greenhouse gas emissions, i.e. a price expressed as a value per ton of carbon dioxide equivalent (tCO_2e).

Carbon tax

A levy on the carbon content of fossil fuels. Because virtually all of the carbon in fossil fuels is ultimately emitted as CO_2, a carbon tax is equivalent to an emission tax on CO_2 emissions.

CBDR

Principle 7 of the 1992 Rio Declaration on Environment and Development reads as follows: "States shall cooperate in a spirit of global partnership to conserve, protect and restore the health and integrity of the Earth's ecosystem. In view of the different contributions to global environmental degradation, States have common but differentiated responsibilities. The developed countries acknowledge the responsibility that they bear in the international pursuit of sustainable development in view of the pressures their societies place on the global environment and of the technologies and financial resources they command"

Circular economy

A circular economy is a systems approach to industrial processes and economic activity that enables resources being used to maintain their highest value and function for as long as possible. Key considerations in implementing a circular economy are reducing and rethinking use, the pursuit of longevity, renewability, reusability, reparability, replaceability, upgradability for products, components and materials.

Circularity

Circularity describes feedback-rich, nested systems; it cues a number of practical approaches such as reduce, reuse, repair, recycling. In a socioecological context it balances natural systems and human production and consumption systems. Circularity concepts are also embedded in many Indigenous Knowledge systems and worldviews.

Co-production

It is a broad concept and approach applied in a variety of public-policy fields for opening up the process of knowledge production, problem-solving, decision-making and public-policy implementation by seriously involving all relevant stakeholders, including scientists, government, practitioners, indigenous groups, civil society, public service users, and others. In environmental sciences and sustainability research, co-production has been defined as an approach of knowledge creation where its producers and users collaborate to generate knowledge fit for the purpose. Such collaboration allows for a better acceptance of the conclusions reached by the decision-makers, based on perception of such decisions as salient, credible and legitimate, and may lead to a change of values and norms in the society (created based on Gerlak et al., 2023).

Cost recovery

A legal process that allows the government to recover the cost of cleanup at hazardous (Superfund) waste sites from those who cause the contamination.

Critical Energy Transition Minerals (CETMs)

Minerals and metals essential for clean energy technologies and infrastructure (e.g., lithium, cobalt, nickel, copper, rare earth elements) where supply risks could affect the energy transition (see also: Critical minerals).

Critical minerals

Critical minerals are a subset of minerals considered crucial for the manufacturing and technological needs of companies, industries, nations, or even the world. The criticality level of minerals is usually determined by the economic importance of the minerals and the risk of disruption to their supply chains.

Current trends scenario

An exploratory scenario that presents a future in which social, economic, and technological trends

follow historical patterns. The GEO-7 current trends scenario does not account for current policies and policy objectives.

Dead zones
Extremely low-oxygen areas in oceans and lakes, caused by excessive nutrient input from human activities coupled with other factors that deplete the oxygen required to support many marine organisms in bottom and near-bottom water.

Debt
Money borrowed by one party from another entity to serve a need that otherwise cannot be met outright.

Decent living standards
Decent living standards (DLS) provide a framework to estimate a practical threshold for the energy, GHG, and material consumption required to alleviate poverty.

Digital dumpsites
These are informal dumpsites and landfills of electrical and electronic waste in low and middle income countries across the globe. Such ineffective waste management and disposal threatens the health and well-being of impoverished city dwellers who live nearby and who also engage in materials recovery through informal processing, such as burning, heating and acid leaching. The resulting environmental pollution poses the greatest risk to children and to pregnant women and their fetuses. The associated pollutants include heavy metals, dioxins, furans and flame retardants, such as polychlorinated biphenyls, polybrominated diphenyl ethers and polycyclic aromatic hydrocarbons. The extent of the problem was brought to light by the World Health Organization report on children and the digital dumpsites in 2021.

Disinvestment strategies
Disinvestment strategy means the strategy by which units in Assets are disinvested where there is insufficient cash in the Product in order to pay charges: to pay Ongoing Adviser Remuneration; when there has been a Failed Payment; or when an Income Payment Strategy fails.

Do-no-significant-harm
The principle originates from the Hippocratic oath in medicine and recently has been expanded to apply in the settings of economic development and innovation, finance, development aid and humanitarian assistance. Various organizations and institutions at international and domestic levels apply it to a different degree and with different underlying definitions, which generally mean that no proposed activities should receive the support and be carried out if they may cause significant environmental and social damage.

Driver
The overarching socio-economic forces that exert pressures on the state of the environment.

Due diligence
The process of a business or organization undertaking a series of structured checks and investigations before undertaking a particular activity in order to ensure that they are fully compliant with the law and any other obligations (for example, in relation to their duty of care to their client, employees, or the general public). The structured nature of the due diligence process is designed to avoid situations in which potentially problematic issues may be accidentally overlooked, leading to allegations of breaking the law or of negligence.

Earth jurisprudence
It is a philosophical approach to legal and governance systems, rather than a theory of international environmental law. It refers to philosophies of law and governance which seek to guide humans to behave in ways that contribute to the integrity, healthy functioning, beauty, and ongoing evolution of the community of life known as "Earth". This approach seeks to promote the flourishing of the Earth Community and a mutually enhancing human-Earth relationship, rather than its subjugation and exploitation by humankind. While the international legal system and the legal systems of almost all states reflect a deeply anthropocentric view. The term was proposed by cultural historian, poet and "geologian" Thomas Berry.

Earth System Boundaries
Proposed safe and just limits – in relation to the climate, the terrestrial biosphere, freshwater, nutrients and air pollution – for maintaining the resilience and stability of the Earth system and minimizing exposure to significant harm to humans from Earth system change.

Economic activity
Economic Activity is the activity of making, providing, purchasing, or selling goods or services. Any action that involves producing, distributing, or consuming products or services is an economic activity. Economic activities exist at all levels within a society. Additionally, any activities involving money or the exchange of products or services are economic activities. For instance, running a small business is a great example of economic activity

Economic system
A means by which governments organize and distribute available resources, services, and goods across a geographic region or country.

Economy
The system of activity connected with the production, trade, and consumption of goods and services of a region, country, or other (not necessarily geographic) area.

Ecosystem services
The benefits people obtain from ecosystems, commonly grouped as provisioning, regulating and cultural services (supporting services underpin these in some frameworks).

Emerging contaminants
Emerging contaminants (ECs), also referred to as contaminants of emerging concern (CECs), are newly identified synthetic or naturally occurring chemicals or biological agents that are detected in the environment and potentially hazardous or recently determined to be hazardous to humans and ecosystems. The risks associated with these contaminants are not fully understood. They may include pharmaceuticals and personal care products (PPCPs), per- and poly-fluoroalkyl substances (PFAS), emerging pathogens, cyanotoxins and other natural toxins, pesticides, industrial chemicals, micro/nano plastics, nanomaterials, antibiotic resistance genes (ARGs), and other exogenous substances that are found in the environment but are not yet well understood in terms of their impacts on humans and natural ecosystems.

Endocrine disruptors
Any chemical, synthetic or natural in origin, that mimics or interferes with the normal actions of hormones in the body. Synthetic endocrine disruptors are used in a wide range of products and materials, from cosmetics and plastics to pesticides and industrial solvents. Because hormones are the chemical messengers of the endocrine system – the network of glands that regulates all essential biological processes, including development, metabolism, and reproduction – exposure to endocrine disruptors is a major health issue and an environmental concern worldwide. Examples of synthetic endocrine disruptors include bisphenol A, dioxin, lead, mercury, polychlorinated biphenyls, styrenes, glycol ethers, parabens, phthalates, and polybrominated diphenyl ethers.

Energy transition
An energy transition is a change in the primary form of energy consumption and production of a given society.

Environmental sustainability
The long term maintenance of ecosystems and other environmental systems for the benefit of future generations.

Environmental tax
Fiscal policy measures used to steer economic burdens away from economically beneficial activities (such as employment) towards environmentally harmful activities (such as the generation of pollution). With this approach, decision-making at every level, by the individual in society up to the highest national Government forum, is steered towards minimizing the environmental impacts of growth.

Environmentally harmful
Environmentally harmful refers to anything that negatively impacts the environment. This can include actions, substances, or conditions that damage air, water, land, or living organisms. Some common examples of environmentally harmful activities include: pollution, deforestation, overexploitation of resources, climate change, land degradation, etc.

Envirotyping
It is a concept and a methodological approach proposed in plant science that proposes to determine and measure the influence of all the environmental factors on plant growth. It has been proposed, as a third "typing" technology, complementing with genotyping and phenotyping. If genotyping aims to specify the genetic composition of a plant and phenotyping specifies the observable characteristics of a plant based on

its genetic information and environmental factors, then envirotyping aims to fill the gap between the two making the impact of environmental factors explicit on plant growth next to specifying its genotype and phenotype. External environmental factors proposed for studying are climate, soil factors, biotic factors, and crop management or cropping system.This approach holds a significant potential for future crop breeding strategies and more efficient crop production in the context of climate change adaptation, food security and sustainability of agriculture.

Equilibrium climate sensitivity
The equilibrium or steady state change in the surface temperature following a doubling of the atmospheric carbon dioxide concentration from pre-industrial conditions.

Eutrophication
The degradation of water or land quality due to enrichment by nutrients, primarily nitrogen and phosphorus, resulting in excessive plant growth and decay, principally of algae. Eutrophication of a lake normally contributes to its slow evolution into a bog or marsh and ultimately into dry land. Eutrophication may be accelerated by human activities that speed up the ageing process.

Externalities (environmental and health)
Costs or benefits arising from production or consumption that affect third parties and are not reflected in market prices (e.g., pollution damages to health and ecosystems).

Extinction debt
The future extinction of species due to events in the past, owing to a time lag between a cause, such as habitat destruction or climate change, and the subsequent disappearance of species.

Feed-in tariff
It is an energy policy supporting the development and dissemination of renewable power generation by individuals, communities, and businesses. In a feed-in tariff scheme, providers of energy from renewable sources, such as solar, wind or water, receive a price for what they produce based on the generation costs. This purchase guarantee is offered generally on a long-term basis, ranging from 5 to 20 years, but most commonly spanning 15-20 years. The cost of the tariff payments are typically shared with the electricity consumers.

Financial market
A market in which financial assets are traded.

Financial product
Any good or service provided by a financial institution. Financial products include loans, mortgages, insurance policies, advice, derivatives, etc.

Financial sector
The part of the economy concerned mainly with lending and borrowing, long or short term. This includes banks, non-bank financial intermediaries such as building societies (UK) or savings and loan associations (US), as well as merchant banks, insurance companies, pension funds, and a range of financial managers and advisers.

Financial system
A financial system is a network of financial institutions.

Fiscal
Fiscal means of or relating to taxation, public revenues, or public debt.

Food sovereignty
The right of peoples and communities to define their own food and agriculture systems.

Food system losses and waste
The combined reduction of food across the food system—from pre-harvest and on-farm handling through storage, processing and distribution to retail, food service and households—encompassing both food loss before retail and food waste at retail and consumption.

Foodshed model
It is a concept and approach gaining popularity in interdisciplinary urban food systems research. It is similar to the concept of watershed in a way that it also describes a flow in a certain geographical area – the flow of food from rural areas to urban areas. The urban foodshed model allows for examining links between urban consumers and rural agricultural production by mapping food flow networks or estimating the potential for local food self-sufficiency. Foodshed model analysis can inform policy related to multiple components of sustainable food systems, including navigating the social and environmental benefits and trade-offs of sourcing food locally, regionally, and globally.

Forever chemicals

These are per- and polyfluoroalkyl substances, a large family of fluorinated chemicals that have partially or completely fluorinated carbon chains of varied lengths. They possess stable structures that give them properties highly sought after in industry. They resist very high heat, protect surfaces from water, grease or friction, and have fire-retardant and stain-resistant properties. They are toxic, hazardous and persist in the environment and in the human body. They accumulate over time and have dangerous effects on the environment and our health. A few subgroups of per- and polyfluoroalkyl substances are currently listed under the Stockholm Convention as industrial persistent organic pollutants.

Fortress conservation

A conservation model based on the belief that biodiversity protection is best achieved by creating protected areas where ecosystems can function in isolation from human interference. It is assumed that local people use natural resources in irrational and destructive ways, and as a result, cause biodiversity loss and environmental degradation. Establishment of protected areas following this model often resulted in the forced displacement and human rights abuses of the Indigenous People who historically lived there and managed the natural resources sustainably. Three principles can characterize protected areas following the fortress model. Local people dependent on the natural resource base are excluded. Enforcement is implemented by park rangers patrolling the boundaries using a "fines and fences" approach to ensure compliance. The only appropriate interferences in the protected areas are tourism, safari hunting, and scientific research.

Free, prior and informed consent

A governance principle according to the Declaration on the Rights of Indigenous Peoples that requires States to consult and cooperate in good faith with the Indigenous Peoples concerned through their own representative institutions in order to obtain their free, prior and informed consent before adopting and implementing legislative or administrative measures that may affect them. Free implies that there is no coercion, intimidation or manipulation. Prior implies that consent is to be sought sufficiently in advance of any authorization or commencement of activities and respect is shown to time requirements of indigenous consultation and consensus processes. Informed implies that information is provided covering a range of aspects, including the nature, size, pace, reversibility and scope of any proposed project or activity; the purpose of the project as well as its duration; locality and areas affected. It also includes a preliminary assessment of the likely economic, social, cultural and environmental impacts, including potential risks; personnel likely to be involved in the execution of the project; and procedures the project may entail.

Fund

A fund is a pool of money set aside for a specific purpose. The pool of money in a fund is often invested and professionally managed in order to generate returns for its investors. Some common types of funds include pension funds, insurance funds, foundations, and endowments.

Fund for responding to Loss and Damage

It is a new climate finance mechanism under the United Nations Framework Convention on Climate Change. The fund has been established to assist developing countries that are particularly vulnerable to the adverse effects of climate change in responding to economic and non-economic loss and damage associated with the adverse effects of climate change, including extreme weather events and slow onset events. By financing recovery initiatives from climate-related losses and damage, the Fund empowers communities to rebuild and adapt. The fund provides resources directly to local actors in vulnerable developing countries through streamlined access processes. It strives for country-led locally driven solutions, ensuring interventions are aligned to country needs, priorities and contexts. Response to loss and damage is a core pillar of climate action, alongside mitigation and adaptation. The Fund mobilizes financial resources through government contributions, private sector partnerships and innovative financing mechanisms, ensuring a robust and sustainable approach to addressing climate-induced loss and damage. The Fund became operational in 2025.

Ghost forest

A maritime forest dieback is the result of saltwater intrusion into freshwater estuaries and other coastal freshwater bodies, as well as the flooding or submerging of low-lying maritime forests due to sea level rise resulting from climate change. Ghost forests may appear anywhere in the world where maritime forests occupy low-lying areas. The haunting sight

of lifeless and decomposing trees is what gives this phenomenon the name.

Global environmental crises

Global environmental crises are those environmental problems that threaten human well-being and hinder progress towards achieving the Sustainable Development Goals (SDGs) and international environmental agreements.

Global food system

Global food system encompasses all the actors and activities related to the production, processing, distribution, trade, retail, preparation, consumption, and end of life management of foods and drinks, as well as the outcomes of these activities, including socioeconomic and environmental, globally.

Global North

Although a formal definition does not exist due to changing socio-economic and political contexts, the Global North is generally comprised of a group of developed countries as classified by the the United Nations Conference on Trade and Development that are predominantly located in the Northern hemisphere, but not exclusively, and can be characterized by some or all features from the following list: high standard of living, high human development index, the presence of robust institutions, rule of law and democratic governance, and industrialized and diversified economies with developed service sectors and leaders in technological development and research. Historically, the core group of the countries in this list have been at the forefront of industrialization and involving geographical exploitation, conquest and colonization.

Global public good

It is a good, a service or a resource with benefits that are public or almost public and universal or near universal. Publicness of its benefits means that consumption or use of this good, service or resource does not diminish its quantity to the other consumers or users, or its consumption or use is non-rival. Secondly, no consumer or user can be excluded from using this good, service or resource, or its consumption and use is non-excludable. Public goods can be local, national, regional and global in scope. Global public goods can be enjoyed worldwide or at least by a group of countries and across generations. Few global public goods are pure in the sense of being truly global, non-rival and non-excludable, but one example is sunlight. Provision of most global public goods is a matter of international collective action by sovereign states, due to the unique characteristics of such goods and of controlling associated positive and negative externalities resulting from their use. Examples of global public goods in the field of environment include climate stability, the UV-protecting ozone layer, global biodiversity, and global knowledge products such as Global Environment Outlooks.

Global South

Although a formal definition does not exist due to changing socio-economic and political contexts, the Global South is best reflected by the scope of development-promoting activities of the United Nations Conference on Trade and Development since its establishment in 1964. The term refers to a group of countries classified by the United Nations Conference on Trade and Development as developing and characterized by some or all features from the following list: lower standard of living, lower human development index, higher poverty rates, underdeveloped infrastructure, poorer quality and outreach of public services such as health and education, higher rates of population growth, and poorer quality housing. The list of Global South countries generally includes those in Africa, Latin America and the Caribbean, Asia and Oceania with a number of notable exceptions, such as Japan, Australia and New Zealand and others. Historically, many countries in this list were subjected to colonialism, which arguably has left a still lasting imprint on their current development levels.

Governance

Governance provides the institutions and the spaces for establishing an overall direction of development, setting targets, coordinating actions, providing regulations, creating specialized organizations and enabling the flow of finance at national and subnational levels. Parliaments and state audit offices should ensure accountability for reporting on progress and learning from failures. Formal government institutions also need to work closely with the private sector, and civil society, providing "safe arenas" for deliberation on policies and instruments of transformation. Good governance enhances synergies and identifies trade-offs and connections while building engagement between politicians, civil society, businesses, youth, labour, media, Indigenous Peoples and local communities.

Green ammonia
Ammonia produced using renewable energy and leading to low life-cycle greenhouse gas emissions. The typical pathway is synthesis via the Haber–Bosch process using nitrogen from air and green hydrogen from renewable-powered electrolysis. Certification schemes set emissions-intensity thresholds and require stringent control of upstream energy sources and supply-chain emissions.

Green bond
A mode of private financing that tap the debt capital market through fixed income instruments (i.e. bonds) to raise capital to finance climate-friendly projects in key sectors of, but not limited to, transport, energy, building and industry, water, agriculture and forestry and waste.

Green finance
Green finance includes any structured financial process or activity that has been undertaken to ensure a better environmental outcome. This includes actions by private and public entities, including banks, governments, companies, non-profit organizations, and others. This finance includes all types of actions and initiatives, such as developing, implementing, and promoting projects that can have sustainable impacts or sustainable business models. Along with making funds available for green projects, another objective of green financing is to better quantify risks related to green projects.

Green growth
The Green Growth approach seeks to create an economic framework which opens up increased opportunities for maximizing the benefits of globalization, such as sharing and transferring knowledge and technologies for eco-efficient production processes, for renewable resource use and for integrated natural resources management as well as for creating new job opportunities. It also advocates eco-efficient and resource-saving economic and production activities based on the full life cycle analysis of production and consumption processes, in which more efficient and less materials-intensive production is cost-effective, reduces emissions and creates new job opportunities. By this means the Green Growth approach attempts to enhance the competitive edge and advantages of the countries in the region on the world trade market, which currently dominates their export-driven economic development.

Green investment
Green investments are traditional investment vehicles (such as stocks, exchange-traded funds and mutual funds) in which the underlying business(es) are somehow involved in operations aimed at improving the environment. This can range from companies that are developing alternative energy technology to companies that have the best environmental practices.

Green job
A green job, also called a green-collar job is, according to the United Nations Environment Programme, work in agricultural, manufacturing, research and development (R&D), administrative, and service activities that contribute(s) substantially to preserving or restoring environmental quality. Specifically, but not exclusively, this includes jobs that help to protect ecosystems and biodiversity; reduce energy, materials, and water consumption through high efficiency strategies; de-carbonize the economy; and minimize or altogether avoid generation of all forms of waste and pollution.

Green methane
Methane produced using renewable energy and leading to low life-cycle greenhouse gas emissions. Typical pathways are: (i) biomethane by upgrading biogas from sustainable biomass; and (ii) synthetic methane (e-methane) by methanating green hydrogen with captured CO_2 (biogenic or atmospheric). Certification schemes set emissions-intensity thresholds and require stringent control of methane leakage across the supply chain.

Green transformation
Green transformation has become one of the most important directions in the further development of the world. It involves the development of green technologies and the creation of legal regulations enforcing, for example, saving energy or reducing the emissions of greenhouse gases, as well as any other activities aimed at changing society's attitude towards the acceptance of frequently more expensive but more environment-friendly technological solutions and legal norms. Thus, green transformation can be defined as combining economic growth with caring about the environment to guarantee a high quality of life for present and future generations at a level which is attainable due to civilizational development, as well as to an effective and rational use of the available resources. Still, there is no single globally accepted

way to this transformation. It is proceeding in a variety of ways and depends on many different factors.

Greenwashing
A practice of presenting companies or products as more environmentally responsible than they are. Greenwashing involves exaggerating or misrepresenting sustainability efforts to mislead consumers into believing that they support meaningful environmental progress. These deceptive practices distort the truth and undermine genuine efforts to reduce environmental harm and improve quality of life.

Gross domestic product
The sum of gross-value-added, at purchasers' prices, by all resident and non-resident producers in the economy, plus any taxes and minus any subsidies not included in the value of the products in a country or a geographic region for a given period, normally one year. Gross domestic product is calculated without deducting for depreciation of fabricated assets or depletion and degradation of natural resources.

Heterozygosity
In the field of genetics it means possession of two different alleles of a particular gene or genes by an individual. Heterozygosity is a measure of genetic variation within a population. High heterozygosity values for a breed may be due to long-term natural selection for adaptation, to the mixed nature of the breeds, or to past mixing of strains of different populations. A low level of heterozygosity may be due to isolation with the subsequent loss of unexploited genetic potential. A high level of average heterozygosity is of critical importance for adaptive response to environmental changes.

Imaginaries
An interdisciplinary concept in humanities and social sciences that represents the ways in which people imagine their social existence, how they fit together with others, how things go between them and their fellows, the expectations that are normally met, and the deeper normative notions and images that underlie these expectations. As such, the concept of imaginaries has important implications for environmental governance. Imaginaries in the context of environment explore how the relationship between people and the environment depend on the specific features of that environment, how the relationships between the society and nature are being shaped by technology and politics, and how environmental governance is being formed. At the same time imaginaries can provide important insights on how the relationships between society and nature could be reconsidered and reshaped into radically different futures.

Inclusive wealth
It is the total value of a country's capital assets – natural capital, manufactured capital and human capital. Manufactured capital refers to investment in roads, buildings, machines, equipment and other physical infrastructure. Human capital comprises knowledge, education, skills, health and aptitude. Natural capital includes forests, fossil fuels, fisheries, agricultural land, sub-soil resources, rivers and estuaries, oceans, the atmosphere and ecosystems more generally. In contrast to the gross domestic product, which measures flows of products and services, inclusive wealth measures stocks of capital and accounts for its primary forms that support the well-being of current and future generations. The trajectory of inclusive wealth signals changes in a country's productive capacity and serves as a measure of its social well-being and sustainable development. The Inclusive Wealth Index is a measure pioneered by the United Nations Environment Programme in response to the beyond gross domestic product movement.

Indigenous and local knowledge
A cumulative body of knowledge, practice, and belief, evolving by adaptive processes and handed down through generations by cultural transmission, about the relationship of living beings, including humans, with one another and with their environment. It is also referred to by other terms such as: Indigenous, local or traditional knowledge, traditional ecological/environmental knowledge, farmers' or fishers' knowledge, ethnoscience, indigenous science, folk science.

Indigenous Peoples and local communities
Indigenous Peoples – also known as first peoples, aboriginal peoples, native peoples, or autochthonous peoples – are ethnic groups who are descended from and identify with the original inhabitants of a given region, in contrast to groups that have settled, occupied or colonized the area more recently. The distinctive groups are protected by international or national legislation that grants them specific rights based

on their linguistic and historical ties to a particular territory, before the later settlement, development, or occupation of a region. A local community is a self-identified human group that relates to a life environment in collective ways and participates in defining a shared territory and culture. The members of a local community frequently have direct encounters and share a common history, traditions, institutions, language, values, and life plans. A local community can be long-standing or relatively new, include a single or multiple ethnic identities, and be permanently settled or mobile. A local community should have a form of political identity that enables it to exercise its rights and responsibilities with respect to its territory and neighbours.

Inequality
Inequality is a multidimensional concept generally understood as the state of being unequal, especially in terms of status, rights and opportunities.

Information asymmetry
According to Nobel laureate Joseph Stiglitz, information asymmetry is an imbalance of information between market participants, and it can lead to market failure. Information asymmetry occurs when different people in a market have different information. For example, a car seller may know more about the quality of their car than the buyer.

Internationally agreed goals
Internationally agreed goals refer to objectives set by international organizations, such as the United Nations, that member countries commit to achieving. These goals are designed to address global challenges and promote sustainable development, peace, and prosperity. A well-known example is the Sustainable Development Goals (SDGs), which were adopted by the United Nations in 2015. The SDGs are a set of 17 goals aimed at ending poverty, protecting the planet, and ensuring that all people enjoy peace and prosperity by 2030.

Invasive alien species
Species whose introduction and/or spread by human action outside their natural distribution threatens biological diversity, food security, and human health and well-being. Alien refers to the species' having been introduced outside its natural distribution (exotic, non-native and non-indigenous are synonyms for alien). Invasive means tending to expand into and modify ecosystems to which it has been introduced. Thus, a species may be alien without being invasive, or, in the case of a species native to a region, it may increase and become invasive, without actually being an alien species.

Investment
In finance, investment is putting money into an activity with the expectation of gaining revenue, which upon thorough analysis, has a high degree of security of principle, as well as security of return, within an expected period of time. For the purpose of UNCCD reporting, investment refers to the use of non-grant instruments allocating financial resources, public or private, for projects, programmes and other relevant activities related to UNCCD implementation.

Key biodiversity areas
These are sites contributing significantly to the global persistence of biodiversity. They represent the most important sites for biodiversity conservation worldwide, and are identified nationally using globally standardized criteria and thresholds. Key biodiversity areas do not necessarily overlap with networks of protected areas. Key biodiversity areas initiative aims to steer the action of governments, business sector, donors, civil society, international organizations, secretariats of multilateral environmental agreements towards a more systemic and global view of preventing species extinctions. It is a global initiative by the world's leading conservation organizations, among them the International Union for Conservation of Nature, Birdlife International, the World Wildlife Fund and others.

Land degradation
A long-term loss of ecosystem function and services, caused by disturbances from which the system cannot recover unaided.

Land Degradation Neutrality (LDN)
A state whereby the amount and quality of land resources necessary to support ecosystem functions and services and enhance food security remains stable or increases; commonly assessed via land cover, land productivity and soil organic carbon.

Levers
Domain of societal influence that shares a configuration of a broad range of actors, actions and analysis.

Local communities
Local Communities as used in IPBES documents that Local communities can be understood as non-indigenous communities which, while highly diverse, are recognized for having historical linkages to places and natural resources, multiple domains of ecological knowledge, dynamic and hybrid resource management techniques and technologies, customary and formal institutions to manage natural resources, and distinctive worldviews and relationships to nature.

Local knowledge
Local knowledge refers to the understandings and skills developed by individuals and populations, specific to the places where they live

Marginalized groups
Those who are systematically excluded and disadvantaged due to factors like gender, age, ethnicity, disability, sexual orientation, or socioeconomic status, leading to their lack of access to power, resources, and opportunities

Market
A market is any place or venue where buyers and sellers can exchange goods and services. A market may be physical, like a retail outlet, or virtual, like an online brokerage with no physical contact between buyers and sellers.

Materials as a service
It is a newly proposed business model by Imperial College London, United Kingdom where companies that supply raw and intermediary materials do not sell their supplies to the end-product manufacturing companies, but instead offer temporary access to them in the form of subscription, usage fee or rent. At the end of the life-cycle, the materials are recovered and repurposed again by the raw material and intermediary goods supplier. It is believed that if adopted, such business models could incentivize sustainable design, support a fairer resource distribution globally, and accelerate progress towards circular economy goals.

Mean species abundance
It is an indicator of naturalness or biodiversity intactness. It is defined as the mean abundance of original species relative to their abundance in undisturbed ecosystems. A mean species abundance of 0% indicates a completely destroyed ecosystem, with no original species remaining.

Multilevel cooperation
Multi-level governance and cooperation mean governments successfully consult one another and work together.

Nationally determined contributions
These are national climate action plans submitted by countries under the Paris Agreement to the United Nations Framework Convention on Climate Change. Nationally determined contributions outline how a country plans to reduce greenhouse gas emissions to help meet the global goal of limiting temperature rise to 1.5°C and adapt to the impacts of climate change. These plans are updated every five years with increasingly higher ambitions, taking into consideration each country's capacity.

Natural capital
Natural assets in their role of providing natural resource inputs and environmental services for economic production. Natural capital includes land, minerals and fossil fuels, solar energy, water, living organisms, and the services provided by the interactions of all these elements in ecological systems.

Nature-based Solutions (NbS)
Actions to protect, conserve, restore, sustainably use and manage natural or modified ecosystems to address societal challenges effectively and adaptively, while simultaneously providing human well-being, resilience and biodiversity benefits.

Non-pricing
Non-pricing tools can play a critical role in reducing emissions and lowering the social and political cost of carbon emissions, especially in countries where typical pricing instruments are difficult to implement due to domestic political, economic, institutional, and social constraints. Higher carbon prices may deliver more emission reductions faster, but national political economy constraints may make this approach difficult to implement, and there are significant challenges in adopting or creating a high carbon price in the short term amid rising inflationary and macroeconomic pressure, particularly in developing countries.

Ocean acidification
The term is used to describe significant changes to the chemistry of the ocean. It occurs when carbon dioxide gas is absorbed by the ocean and reacts with seawater to produce acid. Although carbon dioxide gas naturally

moves between the atmosphere and the oceans, the increased amounts of carbon dioxide gas emitted into the atmosphere, mainly as a result of human activities, such as burning fossil fuels, has been increasing the amount of carbon dioxide absorbed by the ocean, which results in seawater that is more acidic.

One Health

It is an approach to address a health threat at the human-animal-environment interface based on collaboration, communication, and coordination across all relevant sectors and disciplines, with the ultimate goal of achieving optimal health outcomes for people, animals and ecosystems. A One Health approach is applicable at the subnational, national, regional, and global level. The WHO One Health Initiative was established in 2021 and coordinates a quadripartite collaboration involving the Food and Agriculture Organization, the United Nations Environment Programme, the World Health Organization and the World Organisation for Animal Health. It promotes a One Health-related research agenda and leverages cross-sectoral solutions to support regions and countries.

Performance standard

Performance standards in the environment refer to established guidelines or benchmarks that set a level of acceptable environmental impact for businesses or industries, usually requiring them to minimize pollution, resource consumption, and other negative effects on the ecosystem, often measured through emissions limits, waste reduction targets, or specific operational practices; essentially, a set of criteria defining how well a company or activity should perform environmentally, encouraging sustainable practices.

Planetary health

It is a solutions-oriented, transdisciplinary field of research and social movement focused on analyzing and addressing the consequences of human disruptions to Earth's natural systems for human health and all life on Earth. The Planetary Health Alliance is a growing consortium of hundreds of universities, non-governmental organizations, research institutes, and government entities from more than eighty countries around the world committed to understanding and addressing the impacts of global environmental change on human health and well-being. The start of the initiative was the Safeguarding human health in the Anthropocene epoch report published by the Rockefeller Foundation-Lancet Commission on Planetary Health.

Plastic

Non-metallic compounds that result from a chemical reaction, and are molded or formed into rigid or pliable construction materials or fabrics.

Pluriverse

A term that originates from the fields of cosmology and philosophy, it contrasts with the term "universe" as a single unified reality and wholesomeness. Instead, pluriverse presents the theoretical idea of multiple possible universes, where different realities can coexist independently or interdependently. The term has been used in many fields of social sciences, implying underlying complexities of a non-uniform world. In sustainability research, the term is used in the context of post-development theories, critical ecology, and post-colonial studies. The concept of pluriverse in sustainability questions the origins of power, the monopoly of Western thought, knowledge and technology, and their manifestations in the global sustainability agenda, as well as in proposed sustainability solutions. The concept of pluriverse in sustainability research highlights the importance of local contexts and openness to diverse perspectives and solutions. It challenges the shortcomings of universal one-size-fits-all approaches and technical quick-fixes that neglect social justice and preservation of culture. The term multiverse can be used as a synonym for pluriverse.

Polar amplification

Polar amplification describes the phenomenon where surface-temperature change at high latitudes exceeds the global average surface-temperature change. The terms Arctic amplification or Antarctic amplification are used when describing the phenomenon occurring at one of the poles.

Pollution

The presence of minerals, chemicals or physical properties at levels that exceed the values deemed to define a boundary between good or acceptable and poor or unacceptable quality, which is a function of the specific pollutant.

Pressure

Pressure resulting from human activities which bring about changes in the state of the environment (e.g.,

land-use change, resource extraction, emissions of greenhouse gases and air pollutants, introduction and spread of invasive alien species).

Pricing instrument
Pricing instruments can be flexible and provide incentives for cost-effectiveness. They can also reduce long-term abatement costs by encouraging climate-friendly technological change.

Prosumer
A term combining "producer" and "consumer" to describe individuals who are both active creators and consumers of goods and services.

Protected areas
Protected areas and Other effective area-based conservation measures contributing to effective conservation and management; under the Kunming–Montreal Global Biodiversity Framework Target 3, at least 30% of terrestrial, inland water, coastal and marine areas should be effectively conserved and managed by 2030.

Public investment
Public investment refers to investment by the state in particular assets, whether through central or local governments or through publicly owned industries or corporations

Regenerative agriculture
An inclusive agroecosystems approach focused on regenerating living soils, improving biodiversity and ecosystem services while producing food.

Savannization
It is a substitution of tropical rainforests by savanna-like dry grasslands – a replacement of primary rainforest. This refers to both direct human activities, such as deforestation and human-induced forest fires, and self-reinforcing cycles due to climate change, such as higher frequency of natural forest fires and disrupted hydrological systems. The environmental consequences of this process are wide-ranging: biodiversity loss, disruption of the carbon and other mineral cycles, disruption of regional and global climate stability, and land degradation. Some authors discourage the use of this term because it reinforces prejudices against natural savannas. Bottino et al (2024) encourage replacing the term with tropical forest dieback or tropical forest degradation.

Scenario
A plausible, coherent and internally consistent description of how the future may unfold under specified assumptions about key drivers and relationships (not a prediction).

Shared socioeconomic pathways
They are a set of distinct global scenarios describing the future evolution of key aspects of society to analyze possible trajectories for human development and global environmental change during the 21st century. They were developed principally to support climate research, but used extensively for other fields, including biodiversity loss, land degradation and air pollution.

Shock
Shocks, in the environmental context, may include a range of phenomena that are natural or human-caused, from earthquakes, through ecosystem collapses, to abrupt climate changes, wildfires, floods, droughts, pandemics, armed conflicts or any other event with an unpredictable element that damages the environment on which we depend. Such events also weaken political, economic and social systems.

Social capital
Networks together with shared norms, values and understandings that facilitate co-operation within or among groups. Social capital represents the capacity of a community (local or international like the UN) to gather and achieve common goals.

Social cost
Private costs are carried by individuals, companies or other private entities that undertake an action, whereas social costs include additionally the external costs on the environment and on society as a whole.

Social Cost of Carbon
The net present value of climate damages (with harmful damages expressed as a positive number) from one more tonne of carbon in the form of CO_2, conditional on a global emissions trajectory over time.

Social value
Social values refer to value indicators at a social scale, such as social willingness to pay in economics. They can be established by aggregation from individual

values through analytical procedures, or through social processes, such as deliberative valuation, that lead to shared social values.

Socioeconomic
Of, relating to, or involving a combination of social and economic factors.

Solution pathways
A package of actions for system transformation with a sequence that creates a self-sustaining momentum towards achieving recognized goals.

Stranded assets
Assets exposed to devaluations or conversion to liabilities because of unanticipated changes in their initially expected revenues due to innovations or evolutions of the business context, including changes in public regulations at the domestic and international levels.

Structural adjustment
This term refers to governmental policy changes required of developing countries in the 1980s and 1990s to qualify for International Monetary Fund or World Bank financial assistance. This conditional loan and policy reform package came to the rescue of developing countries experiencing economic and financial crises and aimed at restructuring national economies, increasing their trade linkages and altering government spending. The adjustments typically included liberalization of trade and investment policies, removal of government imposed anti-competitive agricultural policies, removal of exchange and price controls, reform of tax policies, cutbacks in government spending, wage reductions, privatization of state enterprises. These reform packages have been criticized based on many problematic aspects. Economically the results were disappointing, while the social and environmental consequences were widespread and have raised concerns.

Subsidies
In the context of international trade, there are two kinds of subsidies: export and domestic. An export subsidy is a benefit conferred on a firm by the government that is contingent on exports. A domestic subsidy is a benefit not directly linked to exports.

Sustainable development
Development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs.

Sustainable finance
Sustainable finance is the process of taking environmental, social, and governance (ESG) principles into account when making investment decisions in the financial sector. This results in more long-term investments in sustainable economic projects and activities.

Sustainable governance
Sustainable government refers to a government that is committed to creating and maintaining conditions under which humans and nature can exist in productive harmony, that permit fulfilling the social, economic and other requirements of present and future generations

Sustainable infrastructure
Sustainable infrastructure systems are those that are planned, designed, constructed, operated and decommissioned in a manner that ensures economic and financial, social, environmental (including climate resilience), and institutional sustainability over the entire infrastructure life cycle. Sustainable infrastructure can include built infrastructure, natural infrastructure or hybrid infrastructure that contains elements of both.

Sustainable intensification
Increasing food production from agricultural land while minimising environmental impacts and enhancing natural capital.

Target-seeking scenarios
Target-seeking scenarios are scenarios that start with the definition of a clear objective, or a set of objectives, specified either in terms of achievable targets, or as an objective function to be optimized, and then identify different pathways to achieving this outcome (e.g. through backcasting). Also known as "normative scenarios".

Telecoupling
It represents socioeconomic and environmental interactions over distances and time. It is an umbrella concept encompassing various types of distant interactions including international trade, tourism, migration, foreign investment, species invasion,

payments for ecosystem services, water transfer, information dissemination, knowledge transfer, and technology transfer and others.

Tipping point
The critical point in an evolving situation that leads to a new and sometimes irreversible development.

Total cost
Total cost, in economics, is the sum of all costs incurred by a firm in producing a certain level of output. It is typically expressed as the combination of all fixed costs (e.g., the costs of a building lease and of heavy machinery), which do not change with the quantity of output produced, and all variable costs (e.g., the costs of labour and of raw materials), which do change with the level of output.

Transformation
A change in the fundamental attributes of natural and human systems, or a thorough or dramatic change in form, composition, structure, appearance, or functionality. In terms of systems, it refers to changes that are fundamental, broad and deep; Transformations can lead to both desirable and undesirable outcomes.

Transformation pathways
Consistent trajectories of change to possible futures stemming from coherent sets of actions to achieve societal goals. Two qualitative and quantitative target-seeking scenarios are developed for GEO-7 that represent alternative Transformation Pathways. They result from integrated solutions that transform the economic and financial, food, energy, materials, and environmental systems, to achieve a set of internationally agreed goals. The set includes limiting global warming to 1.5°C global mean-temperature increase, halting and reversing biodiversity loss, achieving land-degradation neutrality, improving air quality, ending hunger and achieving universal access to clean water and modern energy services. These pathways describe alternative changes in how energy, food, and materials are used and produced, how natural resources are managed, and the pace and direction of technological and behavioural changes.

Transition
The process of changing from one state or condition to another in a given period of time. Transition can occur in individuals, firms, cities, regions and nations, and can be based on incremental or transformative change.

Transition finance
Transition is the journey to sustainable development, and transition finance the financing of that journey.

Unabated fossil fuels
Fossil fuel use without technologies that significantly reduce CO_2 emissions at the point of generation (e.g., high-rate carbon capture and storage).

Universal basic dividend
It is a way of making regular payments to all citizens from revenue raised by charging fees for the use and exploitation of common resources. Universal basic dividend would redistribute a portion of the excess wealth generated by the use and exploitation of the commons to each and every one of a country's citizens. Companies that pollute the commons, extract natural resources, or earn rents on financial assets, would pay fees from their profits into a country's citizen fund. This fund would then distribute equal payments to all citizens in the form of a dividend; the right of every citizen as a co-owner of the commons. It is not means tested or dependent upon government funds. Besides redistributing income to citizens as co-owners, this regular payout would, at the right level, provide essential individual economic security. Such security would likely reduce social tensions, especially during periods of disruption, and encourage the creativity, innovation, and entrepreneurship needed to design the societies of the future.

Value chain
A value chain refers to the full lifecycle of a product or process, including material sourcing, production, consumption and disposal/recycling processes. Value chains are an integral part of strategic planning for many businesses today.

Whole-of-government
A whole-of-government approach refers to deliberates effort to coordinate and integrate actions across government, spanning different departments, agencies, and levels —to achieve shared environmental goals. Rather than limiting environmental responsibility to a single ministry (such as environment or natural resources), this approach sustainability challenges are treated as cross-cutting, requiring collaboration across sectors like finance, transportation, energy, agriculture,

health, and education. Inter-agency committees, staffing rotations, cross-agency budgeting practices and harmonized reporting protocols can facilitate that collaboration. Changes to government structures may also be required for a more far-reaching transformative change approach.

Whole-of-society

A whole-of-society approach refers to a deliberate effort to include and engage all segments of society and plural forms of knowledge —social movements, citizens, Indigenous rightsholders, labour groups, civil society, communities, citizens, and private companies, large corporations, financial institutions, the informal economy, as well as governments —in addressing environmental challenges. Instead, it requires the active and meaningful participation of all actors and agents of change.

Special thanks to UNEP's funding partners. For more than 50 years, UNEP has served as the leading global authority on the environment, mobilizing action through scientific evidence, raising awareness, building capacity and convening stakeholders. UNEP's core programme of work is made possible by flexible contributions from Member States and other partners to the Environment Fund and UNEP Planetary Funds. These funds enable agile, innovative solutions for climate change, nature and biodiversity loss, and pollution and waste.

Support UNEP. Invest in people and planet.
